The next question which arose was the immunisation against diphtheria of susceptible subjects. It was realised that passive immunity could be conferred by injection of antitoxin, and this is done sometimes to protect children in hospital exposed to infection from an outbreak of diphtheria in a ward. But the immunity so conferred is transient, and I have known children so protected contract diphtheria from another source within six weeks of their discharge from hospital. Active and prolonged immunity can only be conferred by injection of the diphtheria toxin in suitable doses at stated intervals. The administration of the unaltered toxin was found to be dangerous. In 1913 Behring suggested the use of toxin-antitoxin as an immunising agent, the toxin being sufficiently neutralised by antitoxin to antagonise its dangerous properties. The use of toxin-antitoxin as a prophylactic against diphtheria was first adopted on a large scale in 1921, in New York City, by Park and Zingher, who were the pioneers in this work. Toxin-antitoxin as a prophylactic has now been superseded by some preparation of "toxoid." This consists of the diphtheria toxin so modified by treatment with formaldehyde that it loses its toxic properties, but retains its virtue as a powerful antigen. This method of preparation was first described in 1923 by Ramon working at the Pasteur Institute in Paris who gave the name of "anatoxin" to the toxin so modified. Since then "toxoid" or "anatoxin" in some form has been in general use there and in this country. Three preparations are employed: (1) toxoid antitoxin, T.A.M. "toxoid" with a small amount of antitoxin added; (2) "toxoid" alone, M.T.; (3) toxoid antitoxin floccules, T.A.F. This consists of the washed and resuspended precipitate which forms when "toxoid" and antitoxin are mixed. The advantages of "toxoid" over toxin-antitoxin are four: it is 20 to 30 times more powerful as an antigen; it contains no serum so there is no risk of sensitisation; it is more stable; and it produces little local or general reaction. T.A.F. is considered to be the most efficient preparation, producing the least local reaction.

In considering prophylaxis against diphtheria we may divide the subjects into three groups: the nurses and staff of fever hospitals; the inmates of large institutions and schools where outbreaks of

NOTES, COMMENTS, AND ABSTRACTS

THE MEDICAL QUARTER[1]

THE medical quarter of London, as Cavendish-square and the surrounding streets are termed here, is described in detail by Dr. Bryan, an outline map illustrating well the development of the district. The ownership of "the manor and parish, in the Hundred of Ossulston, Middlesex, anciently called Tyburn," has had many interesting vicissitudes. Renamed Marylebone, from the Church of St. Mary (not Mary-the-Good, but Mary-at-Burn), it was acquired in the sixteenth century by Henry VIII. from one Hotson, leased by Queen Elizabeth to the Forsyth family, reacquired by James I., pawned by Charles II., seized by Cromwell, and reseized by Charles II. But James I. had sold the Harley-street area back to the Forsyths, from whom it passed by marriage settlement to the Austin family. The Austins sold their property in the reign of Queen Anne to John Holles, a commoner who had married the only child of the Duke of Newcastle, and had been granted the title of his father-in-law, apparently because he was very rich. But Holles had no son, and the property passed to his daughter, Lady Henrietta Cavendish Holles, who married Edward Harley, Earl of Oxford of a new creation, and owner of the Wigmore estate in Hertfordshire, and of the Wimpole estate in Cambridgeshire. Again the property devolved on an only daughter, who married William Bentinck, Duke of Portland, owner of Welbeck Abbey, and a follower of William III. The spendthrift Duke of Chandos acquired the site whereon Chandos-street is built, having one wing of the unfinished Chandos House upon it, while Langham-place and the Langham Hotel are named after Sir John Langham, who built the hotel. The nomenclature of the estate planned by the Portland family is thus comprehensively explained.

In 1720, when Cavendish-square was first laid out, a Dr. James Newton came there to practice, and towards the end of the century we find the famous Matthew Baillie residing there, but it was not until the end of the first quarter of the nineteenth century that the square and three or four streets in its immediate vicinity became a recognised centre for medical consultants, rapidly emptying the famous City centre, Finsbury-square. Since then the names of the medical residents in the area read like a roll-call of successful London doctors; and even more than the square itself, Harley-street, Wimpole-street, Queen Anne-street, and Portland-place keep up the historic connexion with medicine.

Dr. Bryan supplies many interesting biographical notes upon celebrated or notorious residents "round about Harley-street" since the estate was built. With such a varied choice before him among the doctors it is inevitable that his selection for notice should seem capricious, but what he has to say is amusing and substantially accurate. Many of our readers will be interested in the book.

TIMELY AIDS TO THE NEW PHARMACOPŒIA

The twentieth edition of Martindale and Westcott's "Extra Pharmacopœia" (London: H. K. Lewis and Co., Vol. I. Pp. 1216. 27*s.* 6*d.*) just issued gives in a synopsis the principal editions and changes to be effected in the B.P. 1932, as was done on previous occasions (1885, 1898, 1914) when a new edition was brought out. Many of the older preparations will, Mr. Martindale thinks, continue in favour and are accordingly retained with the note (B.P. '14.) —To help in understanding the British Pharmacopœia, 1932, which was first issued for sale on Saturday last, Mr. H. Wippell Gadd, formerly lecturer on pharmacy at the University College, Exeter, has brought out a twelfth edition of his well-known Synopsis (London: Baillière, Tindall and Cox. Pp. 189. 2*s.* 6*d.*), which contains a summary of its requirements for daily reference. The articles and preparations removed from the B.P. 1914 number over 300; all the decoctions have gone, several of the extracts, many of the tinctures and syrups, and there are now no official medicinal wines. A list is given of the principal drugs and preparations of which the composition or the strength has been altered. In addition to its regular features, the Synopsis contains a summary of the Dangerous Drugs Acts, 1920–1932.—A free copy of the B.D.H. Guide to the B.P., 1932, may be obtained on application to the British Drug Houses, Ltd. (Graham-street, City-road, London, N.1), in which attention is directed especially to the preparations which differ materially from the corresponding preparations of the B.P., 1914. Throughout the Guide, which contains 122 large and well printed pages, single and double rules clearly indicate substances which are official for the first time and those which are altered.—Messrs. Woolley Sons and Co., Ltd., of Manchester, have also issued a pamphlet of 83 pages containing the alterations, additions, and deletions in the new Pharmacopœia in a form that will allow of easy reference by pharmacists and medical practitioners.

NEW PREPARATIONS

MULTIBRAL (Messrs. H. R. Napp, Ltd., 3 and 4, Clement's-inn, Kingsway, London, W.C.)—We have received a sample of this preparation of sodium monobromoleate, for which the claim is made that it gives an intensive bromine action 20 times greater than bromides, while it is free from secondary toxic affections. The use of multibral is recommended in conditions of nervous excitability as well as in organic diseases where bromide is customarily prescribed, while the regulation of the dosage is left to the directions of the practitioner.

BOURN-VITA.—This preparation, manufactured by Messrs. Cadbury Bros. Ltd., Bournville, is recommended as a specially palatable method of obtaining the benefits derived from the ingestion of milk, eggs, and cocoa. The preparation contains a large percentage of malt, and as it is easily digested as well as restorative, the manufacturers recommend it specially as "a good-night drink."

SCIATAGO.—This drug, supplied in dragées by Messrs. Coates and Cooper, Ltd. (94 Clerkenwell-road, London, E.C.), combines Phenyl-Quinolin-Carboxylic Acid, Hexamethylene-tetramine and Glycocoll, and is a new attempt to meet the painful symptoms associated with rheumatism, and the myalgic and neuralgic conditions falling under the general headings of lumbago and sciatica, with their associated fibrositis pleurodynia, and other manifestations. The dragée is prepared in accordance with the view that these pathological conditions owe their origin to a deranged metabolism, and the manufacturers claim that they have received clinical testimony that the relief of "rheumatismal affections of the most varied description" has been gratifying. Upon the tin in which the dragées are distributed it is indicated that two may be taken twice daily after meals, but it is advised that they should be used in accordance with the directions of the doctor.

The Glaxo Laboratories (56, Osnaburgh-street, London, N.W.) have sent us a specimen case of AMPOULES, with a price list of the various preparations which can be employed through their medium. The distinctive feature of the ampoules is that they open with a clean break and have no dead space in which part of the solution may accumulate. The firm believe that their prices are 25 per cent. lower than those generally prevalent for such products, economies being secured not only by control of production and distribution of costs, but by the employment of a simple packing. The exact place of breaking the ampoule is indicated in the instructions, and the use of the opener which is supplied is described clearly.

[1] Round about Harley-street. By Dr. Cyril Bryan. London: John Bale, Sons and Danielsson, Ltd. 1932. Pp. 240. 5*s.*

towns throughout America from 1922–26 onwards. In 1921 Park and Zingher immunised 52,000 school-children in New York, using toxin-antitoxin, and by the end of 1923 out of 180,000 children in the city, half were known to be Schick-negative or to have received injections of toxin-antitoxin. Diphtheria mortality and case-incidence steadily declined till 1927, when there was a very severe epidemic of diphtheria and the numbers again rose very considerably. After this disappointing result a diphtheria preventive committee was formed in 1929, and during that year 212,000 immunisations were carried out in New York City, particular attention being paid to the immunisation of young children, and especially of infants 1 year old. As a result of this active campaign in 1930 the mortality had fallen 70 per cent. and the case-incidence 65 per cent. In Philadelphia, with a population of over 2,000,000, by 1929 364,000 children had been immunised, and in 1930 efforts were made to secure immunisation of all susceptible children, and the attack-rate had fallen to the low level of 0·4 per 1000, so that no hospital for diphtheria was required. In Detroit at the end of 1929 153,000 out of 300,000 children were immunised and no case of diphtheria occurred among these, but 1885, or 12·6 per 1000 cases, occurred among the unprotected children. In Chicago, up to 1928, 215,000 children of school and pre-school age had been immunised but, in spite of this, during 1929 the diphtheria mortality and incidence remained high, so in 1930 efforts were made to secure immunisation of 500,000 children during the year. These figures give some idea of the strenuous efforts made to stamp out diphtheria in the large cities in America, and similar steps were taken in other towns throughout the United States.

In Canada diphtheria was for many years one of the chief causes of death in children. Preventive inoculation has been carried out in Ontario since 1920, and throughout the Dominion since 1923–24, and in March, 1929, it was estimated that a total of 500,000 children, or about one-sixth of those under 15, had been immunised. The mortality from diphtheria had fallen from 23·6 per 100,000 in 1921 to 9·4 in 1929, but the attack-rate had not fallen proportionately, though it differed in various provinces. In Ontario, when prophylactic inoculation was general, it fell from 2·0 per 1000 in 1921 to 0·9 per 1000 in 1928, whereas in the province of Quebec, when diphtheria immunisation was not widely practised, it rose from 0·54 per 1000 in 1924 to 1·0 per 1000 in 1929. Energetic measures were then instituted in the latter province in 1929, and immunisation on a wide basis was undertaken and continued in 1930, with satisfactory results. In Hamilton, 120,000 inhabitants, the attack-rate of diphtheria fell from 6·3 per 1000 in 1922 to 0·09 per 1000 in 1927–28, as a result of the immunisation of some 24,000 children between the years 1922–28.

In our own country the first immunisation centre was opened in Holborn in 1922, and during the next four years about 1000 children were Schick-tested and 600 immunised. No further action was taken by other borough councils till 1926, when clinics were opened at Westminster and Camberwell. Since then there has been a gradual and progressive increase in the number of preventive clinics opened in London and throughout the country. In spite of this the total number of Schick-tested in the whole of Great Britain in 1930, according to Dr. Graham Forbes, only amounted to 149,222, the number of inoculated to 129,146, the total number of "protected" (including Schick-negatives) 198,306, a protection-rate of 4·4 per 1000 as compared with 1·2 per 1000 in 1926. In view of these small numbers, it is not surprising that the attack-rate of diphtheria has not fallen in this country.

Most of the statistics quoted have been taken from Graham Forbes's remarkable book on "Diphtheria, its Distribution and Prevention," to which I wish to acknowledge my indebtedness. All the evidence goes to prove that immunisation of the community is a practical proposition. For its success it is essential that preventive inoculation of children should not be delayed till the school age, but that it should be undertaken when they are from 1 to 4 years old, and that a large proportion, two-thirds or more, of the child population should be immunised. Toxoid in some form is an absolutely safe and satisfactory antigen; it should be given in sufficient doses at stated intervals, and a Schick test should be done some two to four months after inoculation to detect those who have not been satisfactorily immunised. The experience of America, Canada, France, and other countries is that preventive inoculation greatly diminishes both the morbidity of and mortality from diphtheria in large towns where the disease is endemic. This country lags far behind the rest of the world in the adoption of preventive measures against diphtheria, in spite of the effort of local health authorities, and it is time that a widespread campaign against this disease should be inaugurated. For its successful issue, as pointed out in a stimulating and instructive leading article in THE LANCET (May 14th, 1932), "there must be effective propaganda and coördinated effort, in order that the public may realise that at the cost of, at most, trifling discomfort to its children, the nation may rid itself of diphtheria with all the suffering, mortality, and expense which the endemicity of this disease entails."

Scarlet Fever

Many years elapsed after the identification of the diphtheria bacillus before anything definite was discovered as to the organism responsible for scarlet fever. The history of the steps of this discovery makes a fascinating story. Klein in 1887 suggested that streptococci were the ætiological factors in scarlet fever, but this view was discredited, and no further addition to our knowledge was made till George and Gladys Dick took up the investigation of the disease, and conclusively demonstrated that hæmolytic streptococci were the cause of scarlet fever. Their first efforts in 1921 were not successful. They inoculated the throats of 30 volunteers with cultures of strains of hæmolytic streptococci from the throats of patients suffering from scarlet fever. The only result was to produce a "sore-throat," and in no instance was there a rash or any characteristic evidence of scarlet fever. Their conclusions were: "The 30 streptococcus throat inoculation experiments constitute a series large enough to discourage further experiments of the same kind with hæmolytic streptococci."

In spite of this they were not downhearted but continued their researches, and in 1923 they had their first success. They took some pus from a whitlow on the finger of a nurse suffering from scarlet fever, and from cultures grown on sheep's blood and agar plates they isolated hæmolytic streptococci. They swabbed the throats of five volunteers with the streptococci they had grown. One developed typical scarlet fever, two sore-throats only, and three were negative. In a second experiment they repeated the process, using the filtrate instead of the culture with negative results on five volunteers. They again diphtheria are liable to occur; and the general public. As regards the first group, for some time past it has been customary to apply the Schick to them, and to immunise all the positives as far as is possible. Figures from Dr. J. Graham Forbes's "Diphtheria, its Distribution and Prevention," show that in the London fever hospitals up to 1931 over 8000 nurses and members of the staffs had been Schick-tested, of whom 2000 were Schick-positive and of these, 1530 had been immunised. As an instance of successful immunisation carried out at an individual fever hospital, we may take that of the City Fever Hospital, Colinton, Mains, Edinburgh. From 1922 to 1931 600 nurses and staff were Schick-tested. Of these, 380 were Schick-positive and 366 of this number were fully immunised. The yearly average number of the staff who contracted diphtheria previous to 1922 was 13 to 14. By 1930 this had fallen to four, an incidence of 2·6 per cent. During the three years 1928, 1929, and 1930, 18 of the staff contracted diphtheria. Of these, five had only just completed the immunisation course, six were Schick-positive six months after inoculation. There were only seven nurses during this period who were Schick-negative, and whose immunity was not sufficient to resist repeated and massive doses of infection where diphtheria admissions were very high. These had mild attacks and recovered.

At the London Fever Hospital the toxin and antitoxin floccules are employed for immunisation and a preliminary dose of 0·25 c.cm. is given. If no marked reaction occurs 1 c.cm. is given on the following day and three weeks later a final dose of 1 c.cm. After a month's interval another Schick test is done. If this is still positive a second course of immunisation is carried out. Since 1926, when immunisation was instituted, 213 nurses have been tested. Of these, 96 were Schick-positive, 81 became immune after one course of T.A.F., 15 required two courses. In 1927 five cases of clinical diphtheria occurred, due to an outbreak of diphtheria in a scarlet fever ward, in nurses who had not yet been immunised against diphtheria. There were also three cases of follicular tonsillitis with a positive throat swab. In 1928 one case of clinical diphtheria occurred in a nurse who had finished the immunisation course two months before. In 1929 a remarkable case occurred in a nurse who had been nursing diphtheria for eight years. She had not been actively immunised, but was Schick-negative and the blood antitoxin was 1/5th of a unit per c.cm., whereas 1/30th of a unit is considered sufficient for protection. She was nursing a case of severe laryngeal diphtheria when she developed typical membranes on one tonsil with virulent organisms. She made a good recovery.

Active immunisation of the staffs of fever hospitals in Great Britain, as throughout the world, has been attended with most satisfactory results, and the value of the Schick test as a test of susceptibility has been amply demonstrated.

Coming to the second group, the active immunisation in schools and large residential institutions is not a general practice, and the question is, as a rule, only raised when recurrent outbreaks of diphtheria take place. The preventive measures carried out on an outbreak of diphtheria usually consist of removal of the case affected, isolation of contacts when practicable, and swabbing the throats and noses of all contacts with a view to detecting "carriers."

The diphtheria bacillus may be found in the throat or nose of healthy persons, "carriers," under the following conditions: it may persist in the throat of a patient convalescent from diphtheria; it may be found in the throat or nose of healthy persons in contact with the disease; it may be found in the throat of persons not known to have been in contact with diphtheria. The control of infection by swabbing throats of contacts, involving extensive bacteriological investigations and isolation of carriers is costly and frequently ineffective, as temporary disappearance of the organism from the throat or nose, or careless swabbing may fail to detect the carrier. All who have had to deal with outbreaks of diphtheria in hospital, schools, and large residential institutions will know how difficult it is to stamp out the infection, as case after case will occur at irregular intervals, in spite of all precautions, endless swabbing of throats, and isolation of detected carriers. Prolonged isolation of carriers when detected, moreover, is very costly, and up to the present no treatment except removal of tonsils in throat carriers has been found to be efficacious, and no satisfactory treatment of nasal carriers has yet been evolved. The least costly and the only effective procedure in dealing with such repeated outbreaks is to employ the Schick test on all the inmates, and not merely the contacts, and to actively immunise all those who are found to be Schick-positive. A striking illustration of the remarkable success from such prophylactic measures is the result obtained by Surgeon-Captain S. F. Dudley[1] at the Royal Hospital School, Greenwich. At this school over 100 cases of diphtheria occurred among the boys in 1921. As a result of precautions, search for carriers and their segregation, the number of cases fell to two during 1923–24. So far, so good, but in the years of diphtheria prevalence 1925–6–7 there were 42, 67, and 46 cases respectively. Surgeon-Captain Dudley then decided on general immunisation of all susceptible boys. From February, 1928, onwards all boys were Schick tested, and those who were Schick-positive were immunised. Toxoid and toxoid antitoxin floccules T.A.F. given in two injections at a month's interval were employed at first, and later T.A.F. only given in three injections at a fortnight's interval between each, as this was found to be the most satisfactory antigen. Another Schick test was done after two to six months interval and those who still remained Schick-positive were given another course. As a result of this intensive campaign, only two cases of diphtheria occurred in 1928, both of these in boys who contracted it before immunisation. The only case that has occurred since up to 1931 was in a boy who required five doses of toxoid before he became Schick-negative and, in spite of this, contracted diphtheria six months later.

Our third group was the community. If preventive measures are undertaken to stamp out diphtheria in large towns or districts, it is essential for their success that a large proportion of the most susceptible subjects —namely, children—should be immunised and that immunisation should be undertaken at an early age. Children as a rule are born with a passive immunity against diphtheria which persists for some time. It is a curious experience to see a mother suffering from diphtheria suckling a young baby and to realise that no precautions need be taken for the infant's safety. Investigations to determine when the immunity ceases suggest that the child becomes susceptible at three months, though in some cases the immunity appears to last rather longer.

America and Canada were far ahead of this country in instituting general prophylactic measures against diphtheria. Preventive measures on a large scale have been carried out in most of the States and large groups by serological methods, the remainder being of the "heterogeneous type." In view of the large percentage of inagglutinable hæmolytic streptococci in the latter group, they concluded that it is not possible accurately to correlate the type of streptococcus with the clinical type of scarlet fever. Since 1926 they have treated 670 cases of scarlet fever with scarlatinal antitoxic serum with beneficial results. The temperature fell to normal in 60 per cent. of cases, and there was a rapid improvement in the general condition and that of the throat. They also found that it reduced the number of complications. They came to the conclusion that the results of routine treatment of scarlet fever by scarlatinal antitoxin were good, though not to be compared with those obtained by the use of antitoxin in diphtheria. In common with all who have to do with fever hospitals, they found that there is a considerable proportion of Dick-positive reactors in convalescent scarlet fever patients, and they consider that the number is greater in those treated with antitoxin.

After these devastating criticisms by bacteriologists of the hæmolytic streptococcus responsible for scarlet fever, it is a relief to turn to the successful results obtained, despite all obstacles, by the Dicks themselves and other clinicians who have profited by the discoveries made. The Dicks stated in 1929 [6] that since 1923, when they discovered the skin test of susceptibility to scarlet fever, they have made tests on 32,400 persons. Of these 20,856 gave negative reactions. 11,584 persons with positive reactions were immunised, and no case of scarlet fever occurred among these, though they resided in institutions where outbreaks of scarlet fever occurred from time to time. They also immunised 1191 nurses and residents in fever hospitals, and none of these contracted scarlet fever. Controls were furnished by 37 cases which occurred in persons who had not been immunised. Drs. Blatt and Dale [7] have described how they dealt successfully with repeated outbreaks of scarlet fever at a hospital by Dick-testing and immunising the susceptible in the St. Vincent Maternity and Infant Hospital, which provides 170 beds for children under five. Cases of scarlet fever occurred at irregular intervals over a considerable period. Case 1 preceded Cases 2 and 3 by 19 days, Cases 2 and 3 preceded Case 4 by 14 days, Case 4 preceded Case 5 by 16 days, so infection could not have occurred by direct contact. Moreover, some of the cases were on different floors, so it appeared most probable that adult "carriers" having access to more than one floor were the means of transmission. Of a total of 271, including mothers, nurses, and children, 61 were found to be Dick-positive; of these 43 were children: 46 of the Dick-positive were immunised by injections of scarlet fever toxin at five days' intervals. Adults with hæmolytic streptococci in the throat wore special masks till the cultures became negative. The measures taken were successful, no further cases occurred, and it was not found necessary to close the hospital as had been proposed.

For satisfactory results in immunisation in Great Britain I would refer to those obtained by Dr. W. T. Benson, medical superintendent of the City Hospital, Edinburgh.[8] This observer, over a period of the five years, 1923–27, immunised the staff of a fever hospital, with the result that the incidence of scarlet fever among the staff fell from 8·59 per cent. in 1924 to 0·67 per cent. in 1927. In the latter year there were only six cases, of which four developed scarlet fever before immunisation. He gave four injections of the toxin prepared by Dr. R. A. O'Brien at the laboratories of Messrs. Burroughs Wellcome in doses of 500, 1000, 5000, and made 20,000 skin tests over a period of four weeks. As a result of his investigations, he came to the conclusion that the Dick test is a reliable index to susceptibility to scarlet fever. This conclusion was supported, not only by his experiences in respect of immunisation, but by the following: 97 cases wrongly suspected of being cases of scarlet fever were admitted to scarlet fever wards and found to be Dick-negative. None of these contracted scarlet fever. Thirty-six cases exposed to infection, which were Dick-positive, contracted scarlet fever.

At the London Fever Hospital during the last four years 178 nurses have been tested. Of these 113 were Dick-negative and 65 Dick-positive. Of the latter 48 were immunised, 17 left before this was done. No case of scarlet fever has occurred among the nurses who were immunised or who were Dick-negative when tested.

In France Dr. Radoyé,[9] during 1926–27, performed 1367 Dick tests on students in military academies, and immunised 725 who were Dick-positive. As a result, no case of scarlet fever occurred for two years, whereas previously no year had elapsed without an outbreak of the disease. Dr. Hélène Sparrow,[10] in Poland, organised immunisation of children on a large scale in 1925. During the years 1925–27 23,657 children were Dick-tested. The percentage of Dick-positive was 55 to 57, and these were immunised. Dr. C. O. Stallybrass [11] carried out immunisation of Dick-positive subjects in various institutions and orphanages in Liverpool, where outbreaks of scarlet fever kept recurring, with the result that no further cases developed. The above instances, which could be multiplied, demonstrate the successful results which have been obtained by prophylactic inoculation against scarlet fever.

Antitoxin.—As regards the antitoxin, which has been extensively employed both in this country and throughout the world, all those who have made use of it agree that usually it produces a rapid fall of temperature and greatly alleviates the local and constitutional symptoms, but opinion varies as to its efficacy in preventing complications. Drs. Burton and Balmain have had favourable experience of its use. The Dicks, as a result of their observations, find that mastoiditis occurs three times as frequently, and nephritis four times more frequently in controls than in those treated with antitoxin. Dr. Taketo Tsuda has reported that between January, 1929, and March, 1930, he treated every case of scarlet fever with serum (40 c.cm.). As the result of his observations he came to the conclusion that if given in the first 24 hours in sufficient doses it ensures *a cure and prevents complications.* The later it is given the less its efficacy in regard to prevention of complications; if given later than 72 hours after the onset of the attack it is useless. Drs. Friedemann and Deicher treated a number of cases of children in Berlin with antitoxin. They found that a rapid fall of temperature with amelioration of symptoms and early disappearance of the rash resulted. As regards complications, it only appeared to be of value in preventing suppurative lesions, but no difference was noted in respect of incidence of nephritis and adenitis. My own experience at the London Fever Hospital is that it causes a rapid amelioration of local and constitutional symptoms, that so-called "scarlatinal rheumatism" occurs much less frequently as a complication since the use of antitoxin, but I have been disappointed used an unfiltered culture for their experiment, and of four volunteers one developed scarlet fever and two sore-throats. They then came to the conclusion that scarlet fever was caused by a hæmolytic streptococcus or some unrecognised organism closely associated with it in cultures. Early in 1924 they demonstrated that the filtrate of the culture of hæmolytic streptococci which produced experimental scarlet fever gave a positive reaction when injected intradermally in a large percentage of persons who had not had scarlet fever, but no result in patients convalescent from scarlet fever. The positive reaction consists of a small circumscribed erythematous area which appears in four to six hours after the intradermal injection of 0·1 c.cm. scarlatinal toxin, diluted to 1 in 1000. This reaches its maximum in 18 to 36 hours and then fades, leaving some pigmentation or desquamation. This was the origin of the "Dick test." Experimenting further, the Dicks found that injection of serum from patients convalescent from scarlet fever into a Dick-positive subject neutralised the toxin and caused a Dick-negative reaction in a subsequent test. This suggested to them that the toxin might be utilised to produce active immunity, and they proceeded to inject a Dick-positive subject with doses of the toxin. Too large a dose was employed at first, which produced severe local and general reaction, vomiting, pyrexia, and a slight scarlet rash; subsequently the patient became Dick-negative. When used in suitable dilution in repeated doses the reaction was slight, and the patient became Dick-negative.

A. R. Dochez and L. Sherman [2] in the same year confirmed the results of the Dicks, and tried unsuccessfully to produce scarlet fever in various animals. Further, they immunised a horse by a series of injections of the scarlet fever toxin extending over six months. They obtained from the horse a serum which blanched a scarlet fever rash when injected intradermally, and, when injected subcutaneously in sufficient doses into a patient suffering from scarlet fever, caused a rapid fall of temperature and disappearance of the rash, the Dick-positive reaction becoming negative. In 1918 it had been shown that blanching of the scarlet fever rash took place locally when serum from a convalescent scarlet fever patient was injected intradermally. In the light of these discoveries it seemed that the Dick test was exactly analogous to the Schick test in diphtheria, and that it would be a simple matter to produce active immunity to scarlet fever by injection of suitable doses of the toxin at stated intervals, and to neutralise the ill-effects of the toxin in a patient suffering from scarlet fever by antitoxin, as in diphtheria. To a certain extent these hopes have been fulfilled, but the conditions are different. It is impossible to standardise the scarlatinal toxin or antitoxin, since no suitable animal for experimental purposes has yet been discovered except man, and he does not readily offer himself as a subject except perhaps in America to oblige the Dicks.

Prof. C. C. Okell,[3] in the Milroy lectures of the Royal College of Physicians of London for 1932, on the rôle of hæmolytic streptococci in infective disease, raises the question as to the specificity of the scarlet fever organism. He points out that there are two main views held as to the relationship of streptococci to disease. "The first, that each well-defined clinical entity is associated with a special kind of streptococcus, the 'specificity' view expressed in the use of such names as *S. scarlatinæ*, *S. erysipelatis*, &c. The second view is that different diseases due to the hæmolytic streptococcus are due essentially to one species. According to this view, factors of varying virulence and toxicity on one side and varying susceptibility on the other are held to account for the different streptococcal diseases outwardly so unlike." This he terms the "unitarian" view, and in his interesting and suggestive lectures he supports it. He ascribes to the hæmolytic streptococcal exotoxin these important offensive weapons: (1) An erythrogenic or rash-producing toxin, immunologically identical, from whatever source the strain is derived. For this a neutralising serum is available under the name of "scarlatinal antitoxin." (2) A pyogenic property, common to all hæmolytic streptococci to which no antibody has yet been discovered. (3) An invasive property or power to pass the local defences and infect the blood. These three elements, in the attack of the hæmolytic streptococcus, he states, vary in intensity, as does also the strength of the host's defence. Hence the great variation in the clinical and pathological manifestations when man is subjected to the attack of the hæmolytic streptococcus. In further support of his "unitarian" theory, Okell refers to epidemics in which scarlet fever or simple sore-throats are propagated indifferently, and suggests that in these instances the streptococcus, at first non-scarlatinal, has exalted its toxigenicity by passage from individual to individual till it arrives at a phase when it can produce scarlet fever in a Dick-positive individual.

Dr. Alison Glover and Dr. F. Griffith, writing on "Acute Tonsillitis and some of its Sequels"[4] as a result of investigations on epidemics of sore-throat and scarlet fever in a number of schools, found that cases of tonsillitis without rash occur in scarlet fever epidemics side by side with scarlet fever cases. But their conclusions, which are as follows, do not quite match with those of Prof. Okell: (1) Epidemic tonsillitis is due to a hæmolytic streptococcus. (2) Invasion of the throat by a hæmolytic streptococcus may produce: symptomless infection in a healthy carrier, tonsillitis, fever and pharyngitis, or scarlet fever; and any of the three latter may be followed by otitis media or rheumatism. They also conclude that many serological types of hæmolytic streptococci may cause scarlet fever, but four chief types predominate which are responsible for about 70 per cent. of cases. The remaining 30 per cent. are due to strains of a "heterogeneous type" which cannot be classified. Epidemic tonsillitis, they hold, is due to strains from the "heterogeneous group," which may, however, give rise to scarlet fever in susceptible individuals. Griffith, in 1928, had already published a paper in which he differentiated by agglutination methods four separate types of scarlatinal streptococci comprising 70 per cent. of the whole.

Dr. V. D. Allison and Dr. William Gunn, at the Park Hospital, carried out a series of investigations during 1927–28 on over 200 cases of scarlet fever, with a view to determine, if possible, a serological classification of the hæmolytic streptococci responsible for scarlet fever. They found that four different types could be differentiated by agglutination methods comprising about 54 per cent. of the total, and 46 per cent. were "heterogeneous" strains, which possessed no antigens in common with any of the four differentiated types.

Dr. A. R. Balmain and Dr. A. H. G. Burton,[5] during 1928, carried out a series of investigations on 265 cases of scarlet fever: 79 per cent. showed hæmolytic streptococci in the throat; of these, 46·1 per cent. could be classified under one of Griffith's four

SUBCUTANEOUS RUPTURE OF THE POPLITEAL ARTERY

A REPORT OF TWO CASES

By Cecil P. G. Wakeley, F.R.C.S. Eng., F.R.S. Edin.

SURGEON TO KING'S COLLEGE HOSPITAL AND THE BELGRAVE HOSPITAL FOR CHILDREN; CONSULTING SURGEON TO THE HAMMERSMITH AND MAUDSLEY HOSPITALS

AND

W. Ogilvy Reid, B.Sc., M.B., F.R.C.S. Edin.

LATE CASUALTY OFFICER, MILLER GENERAL HOSPITAL

Subcutaneous rupture of the popliteal artery is apparently rare, and no detailed account of the condition seems to be extant in the English language. As far as we can discover four cases only have been recorded since the late war. We feel convinced, however, that the lesion is probably not so rare as the number of recorded cases would lead one to expect. The condition is very serious and any hope of saving the affected limb is entirely dependent upon early diagnosis and treatment. The causes of the injury are varied and numerous, and our purpose of insisting upon the seriousness of the condition can be best served by first describing two typical cases.

TWO CASE RECORDS

Case 1.—A man aged 23, a strong healthy stoker, was playing in a game of football. While so engaged he ran to kick the ball, completely missed it, fell down, and cried out on account of sudden acute pain in his right knee-joint. The knee became very swollen and could not be extended voluntarily. Two hours after the accident the pain in the knee-joint was not so severe but pain in the hip-joint commenced. He was admitted to the Royal Naval Hospital, South Queensferry, on May 19th, 1916, four hours after the accident.

When he was examined on admission the right knee-joint was found to be swollen and the leg cold. The dorsalis pedis artery could not be felt. An X ray examination of the leg did not reveal any fracture. The knee-joint was flexed at an angle of 45 degrees, and any attempt at extension caused him considerable pain. The patient was put to bed, and the right leg supported on a pillow and encased in cotton-wool. The patient passed a very restless night, but next day all pain had disappeared from the limb, except for some intermittent shooting pain in the right hip-joint.

The leg was found to be quite cold and sensation was absent from the foot. The knee was considerably distended and there was some œdema over the tibia. The conclusion that the popliteal artery was lacerated in the region of the knee-joint was arrived at, and it was decided to tie the femoral artery and vein in Hunter's canal, the only treatment which held out any prospect of saving the limb. As the swelling about the knee was relatively very great, exposure of the popliteal artery in the popliteal space was obviously a hopeless procedure.

Under ether anæsthesia the femoral artery and vein were ligatured in Hunter's canal some 20 hours after the injury. When the femoral vessels were exposed, the surrounding tissues were found to be infiltrated with blood and exact differentiation was difficult. The leg was encased with cotton-wool and slung up in a frame. The limb remained cold in spite of the treatment, and no sign of pulsation could be distinguished in the arteries of the leg. Two days later gangrene of the foot commenced and the patient began to complain of acute pain in the leg and toes. Amputation was decided upon and was carried out under open ether anæsthesia. A supracondylar circular amputation was performed. When the popliteal artery was exposed it was found to be ruptured just below the opening in the adductor magnus muscle. There was a large rent in the vein at a lower level. The wound was drained with two large drainage-tubes as the tissues were considerably infiltrated with blood. The amputation stump healed well, and the drainage-tubes were removed on the third day after the operation. The patient was able to leave the hospital three weeks after the operation.

The amputated leg was carefully dissected; the popliteal space was one large hæmatoma and the knee-joint was also full of blood. The posterior ligament of the knee-joint was partly ruptured in its middle third in the regions of the intracondylar notch, but all the other ligaments of the knee, both extra- and intra-articular, were intact. There was no sign of any fracture or disease of the bones or ligaments. The popliteal artery was almost completely ruptured just below the opening in the adductor magnus muscle. There was no sign of disease of the vessel wall and the branches of the artery were all intact. The popliteal vein was ruptured about the middle of the popliteal space and its rupture was complete, the two ends of the vessel being separated, one from the other, by a distance of about half an inch. The tissues in the popliteal space were all infiltrated with blood. A section of the artery was examined microscopically and was reported to be quite normal, there being no sign of disease in the walls of the vessel. A piece of synovial membrane of the knee-joint was also examined microscopically, but it was also found to be quite normal and showed no evidence of disease.

Case 2.—A lad of 15 was cycling along Greenwich-road one day in September, 1927, when the front wheel of his bicycle collided with the edge of a tram-line raised slightly above the level of the road. He was thrown off his bicycle in front of a heavy Foden steam-wagon which he alleged passed over both his legs. This was the patient's story, and he subsequently sued both the L.C.C. tramways and the owners of the wagon for negligence. The case, however, went to the King's Bench Division and was heard before a jury, and it was conclusively agreed that the lad was not run over. The actual mechanism of the injury, however, remained a mystery, despite the investigations of learned counsel, and judgment was given that the unfortunate litigant sustained the lesion as a result of falling from his bicycle, and he consequently lost his case.

When brought into the Miller General Hospital the patient was suffering from some degree of shock. He complained of pain in the region of the left knee, but could move the foot and leg on that side, and apparently experienced no loss of sensation, or numbness, tingling, &c. His left knee was considerably swollen in the region of the joint. There was no bruising and no evidence of the limb having been subjected to any crushing violence. A provisional diagnosis of fracture of the patella with associated traumatic synovitis was made, and the patient was admitted to hospital. A rupture of the popliteal artery was not taken into consideration at this stage, and whether pulsation in the tibial arteries was present or absent was not observed.

On the following day the patient complained of numbness of the foot and toes and tingling in the leg, and it was then noted that pulsation in the tibial arteries was absent. A diagnosis of rupture of the popliteal artery was made by Mr. R. C. B. Ledlie, who decided to operate. The artery was exposed and a large quantity of blood clot was evacuated from the popliteal fossa. No muscle bruising was evident, but the muscles and other soft parts in the region appeared to be infiltrated with blood, the latter having percolated for some distance upwards into the thigh and downwards into the leg. The artery was partially ruptured about half an inch distal to the hiatus in the adductor magnus. The vein was intact; no nerve lesion was detected. The artery was ligatured above and below the rupture, the vein being left unligatured. The wound was then closed and drainage-tubes inserted.

This palliative operation was performed some 30 hours after the accident. The following day, that is, on the third day following the injury, evidence of incipient gangrene began to appear, and amputation was decided upon. This was carried out through the junction of the upper and middle thirds of the femur.

The patient made an uneventful recovery, and was seen about one year later, walking well, with a pylon attachment to the stump.

ÆTIOLOGY

In cases of ruptured popliteal artery associated with gross lesions in the region of the knee—e.g., fractures, dislocations, and those due to a crushing violence, such as occur when the limb is run over—the cause of the rupture is usually obvious. Schultz,[1] in his excellent review of 45 cases, gives an analysis of causes, and in his series there were 11 due to various forms of crushing violence, 11 due to luxation of knee, 5 due to fracture at lower end of femur, and 1 other referred to below. Harrison Cripps[2] records an interesting case in which a man had his leg pushed along in front of a braked wheel, which did not pass over the limb, and remarks that "the mechanism of rupture would appear to be the result of a force acting in an oblique direction, from below upwards, on the lower part of the femur." The artery gave way to find that it does not prevent the occurrence of middle-ear disease and mastoiditis or adenitis, though their incidence is reduced somewhat.

I think you will agree that the successful results obtained in immunisation against scarlet fever are remarkable in view of the impossibility of standardising the toxin or isolating a specific organism. The hæmolytic streptococci appear to be elusive and protean in character, and are responsible for many evils besides scarlet fever and its various complications, and it does not seem possible to sort them out satisfactorily.

I shall say little about the remaining infectious fevers as no recent discoveries have been made in connexion with them.

Measles

The micro-organism for this disease has not yet been isolated. Serum, however, from individuals convalescent from measles has been used successfully for the temporary immunisation of young children exposed to infection. This is of service in preventing the spread of the disease in hospitals and institutions, and for protecting infants and very young children in the case of whom an attack of measles might prove serious. The serum should be given before the sixth day of incubation to be effective.

Whooping-cough

Drs. Bordet and Gengou, working at the Pasteur Institute, isolated the bacillus of whooping-cough in 1906, which they cultured on a special medium of extract of potato and agar-agar with citrated or defibrinated blood. Various authors have confirmed their findings. Drs. Lawson and Mueller[12] isolated the bacillus in 259 out of 1115 cases examined, including 23 cases in the catarrhal stage. They found that there were two effective ways of obtaining cultures: by insulating Bordet-Gengou plates with pellets of sputum expectorated; and by holding a culture plate in front of a patient during a paroxysm of coughing. They claimed that vaccine treatment instituted early in the incubation period would often protect the patient. This, however, is a difficult matter to prove and has not been confirmed. Drs. Saure and Hambrecht[13] claimed that in a series of 200 cases they isolated the organism in 52 out of 53 cases in the catarrhal stage, and in 70 in the paroxysmal stage, but never in the declining stage. They considered that identification of the bacillus in the catarrhal stage was valuable as a means of early diagnosis for purposes of isolation.

Chicken-pox

Nothing definite is known as to the causative organism of chicken-pox, and the only point of interest which arises is that of the association of herpes zoster with chicken-pox.

In 1917 Le Feuvre wrote a paper[14] on "A plea for the common origin of shingles and chicken-pox." He collected 50 cases in which the two conditions were associated, which he classified under three headings: chicken-pox in one individual contracted from contact with shingles in another; shingles contracted from contact with a case of chicken-pox; shingles and chicken-pox occurring together in one individual. Of the 50 cases 41 came under the first heading, 5 under the second, and 4 under the third. The most common occurrence was the development of chicken-pox in a child following contact with shingles in an adult. The incubation period corresponded with that of chicken-pox. Dr. James Taylor[15] referred to Le Feuvre's paper, and quoted cases in which chicken-pox followed contact with herpes, and in a later paper[16] stated that since he had raised the question, several medical men had sent in accounts of similar cases. Personally, I have come across two cases falling under the third heading, in which a well-marked attack of herpes was followed in two or three days by chicken-pox in the same individual. Of course, the association of the two diseases is the exception rather than the rule, but it is interesting to find so many cases on record.

Conclusion

I have endeavoured to trace the great advance in our knowledge of the problems of immunity in connexion with diphtheria and scarlet fever. As regards the former, the success has been such that it would be possible to eradicate the disease from the country by the prophylactic measures now at our command.

As regards scarlet fever, universal immunisation, in the present state of our knowledge, is not a practical proposition, but such success has already been attained in the protection of those exposed to infection in fever hospitals that it may be feasible in the near future. Scarlet fever, however, is not so widespread as diphtheria, and if only a serum can be produced as efficacious in preventing its disastrous complications, as in the case of diphtheria, the need is not so pressing, though an enormous saving of expense to the taxpayers by the abolition of fever hospitals as well as great benefit to the public might be attained by the elimination of diphtheria and scarlet fever.

One word of warning. If these diseases are abolished as the result of what one may term "artificial" immunisation, this must be maintained indefinitely. At the present time natural immunity is to a great extent conferred on the community by droplet infection or mild doses of virus from "carriers" or patients, so that the "herd" are more or less salted. If all Nature's measures for protecting the community are withdrawn, and infection is introduced into an entirely unprotected community, a colossal epidemic might follow.

NEW SCHEME TO HELP HOSPITALS.—It is stated that the British Charities Association has given its approval to a new scheme for raising money for hospitals, and has expressed a hope that it will be well supported. Manufacturers are being asked to contribute to a central hospital fund one farthi [illegible]
net sales, and it is sugges [illegible]
will be sufficient to solve [illegible]
The manufacturers woul [illegible]
of their goods, which would, where practicable, be marked with the words "Pledged support," and buyers would be asked to give preference to such goods. It is stated that many firms have promised their support to the scheme. It is proposed that a national hospital committee should supply participators with a distinctive emblem which could be used in advertisements.

SUBCUTANEOUS RUPTURE OF THE POPLITEAL ARTERY

A REPORT OF TWO CASES

By Cecil P. G. Wakeley, F.R.C.S. Eng., F.R.S. Edin.

SURGEON TO KING'S COLLEGE HOSPITAL AND THE BELGRAVE HOSPITAL FOR CHILDREN ; CONSULTING SURGEON TO THE HAMMERSMITH AND MAUDSLEY HOSPITALS

AND

W. Ogilvy Reid, B.Sc., M.B., F.R.C.S. Edin.

LATE CASUALTY OFFICER, MILLER GENERAL HOSPITAL

Subcutaneous rupture of the popliteal artery is apparently rare, and no detailed account of the condition seems to be extant in the English language. As far as we can discover four cases only have been recorded since the late war. We feel convinced, however, that the lesion is probably not so rare as the number of recorded cases would lead one to expect. The condition is very serious and any hope of saving the affected limb is entirely dependent upon early diagnosis and treatment. The causes of the injury are varied and numerous, and our purpose of insisting upon the seriousness of the condition can be best served by first describing two typical cases.

TWO CASE RECORDS

Case 1.—A man aged 23, a strong healthy stoker, was playing in a game of football. While so engaged he ran to kick the ball, completely missed it, fell down, and cried out on account of sudden acute pain in his right knee-joint. The knee became very swollen and could not be extended voluntarily. Two hours after the accident the pain in the knee-joint was not so severe but pain in the hip-joint commenced. He was admitted to the Royal Naval Hospital, South Queensferry, on May 19th, 1916, four hours after the accident.

When he was examined on admission the right knee-joint was found to be swollen and the leg cold. The dorsalis pedis artery could not be felt. An X ray examination of the leg did not reveal any fracture. The knee-joint was flexed at an angle of 45 degrees, and any attempt at extension caused him considerable pain. The patient was put to bed, and the right leg supported on a pillow and encased in cotton-wool. The patient passed a very restless night, but next day all pain had disappeared from the limb, except for some intermittent shooting pain in the right hip-joint.

The leg was found to be quite cold and sensation was absent from the foot. The knee was considerably distended and there was some œdema over the tibia. The conclusion that the popliteal artery was lacerated in the region of the knee-joint was arrived at, and it was decided to tie the femoral artery and vein in Hunter's canal, the only treatment which held out any prospect of saving the limb. As the swelling about the knee was relatively very great, exposure of the popliteal artery in the popliteal space was obviously a hopeless procedure.

Under ether anæsthesia the femoral artery and vein were ligatured in Hunter's canal some 20 hours after the injury. When the femoral vessels were exposed, the surrounding tissues were found to be infiltrated with blood and exact differentiation was difficult. The leg was encased with cotton-wool and slung up in a frame. The limb remained cold in spite of the treatment, and no sign of pulsation could be distinguished in the arteries of the leg. Two days later gangrene of the foot commenced and the patient began to complain of acute pain in the leg and toes. Amputation was decided upon and was carried out under open ether anæsthesia. A supracondylar circular amputation was performed. When the popliteal artery was exposed it was found to be ruptured just below the opening in the adductor magnus muscle. There was a large rent in the vein at a lower level. The wound was drained with two large drainage-tubes as the tissues were considerably infiltrated with blood. The amputation stump healed well, and the drainage-tubes were removed on the third day after the operation. The patient was able to leave the hospital three weeks after the operation.

The amputated leg was carefully dissected ; the popliteal space was one large hæmatoma and the knee-joint was also full of blood. The posterior ligament of the knee-joint was partly ruptured in its middle third in the regions of the intracondylar notch, but all the other ligaments of the knee, both extra- and intra-articular, were intact. There was no sign of any fracture or disease of the bones or ligaments. The popliteal artery was almost completely ruptured just below the opening in the adductor magnus muscle. There was no sign of disease of the vessel wall and the branches of the artery were all intact. The popliteal vein was ruptured about the middle of the popliteal space and its rupture was complete, the two ends of the vessel being separated, one from the other, by a distance of about half an inch. The tissues in the popliteal space were all infiltrated with blood. A section of the artery was examined microscopically and was reported to be quite normal, there being no sign of disease in the walls of the vessel. A piece of synovial membrane of the knee-joint was also examined microscopically, but it was also found to be quite normal and showed no evidence of disease.

Case 2.—A lad of 15 was cycling along Greenwich-road one day in September, 1927, when the front wheel of his bicycle collided with the edge of a tram-line raised slightly above the level of the road. He was thrown off his bicycle in front of a heavy Foden steam-wagon which he alleged passed over both his legs. This was the patient's story, and he subsequently sued both the L.C.C. tramways and the owners of the wagon for negligence. The case, however, went to the King's Bench Division and was heard before a jury, and it was conclusively agreed that the lad was not run over. The actual mechanism of the injury, however, remained a mystery, despite the investigations of learned counsel, and judgment was given that the unfortunate litigant sustained the lesion as a result of falling from his bicycle, and he consequently lost his case.

When brought into the Miller General Hospital the patient was suffering from some degree of shock. He complained of pain in the region of the left knee, but could move the foot and leg on that side, and apparently experienced no loss of sensation, or numbness, tingling, &c. His left knee was considerably swollen in the region of the joint. There was no bruising and no evidence of the limb having been subjected to any crushing violence. A provisional diagnosis of fracture of the patella with associated traumatic synovitis was made, and the patient was admitted to hospital. A rupture of the popliteal artery was not taken into consideration at this stage, and whether pulsation in the tibial arteries was present or absent was not observed.

On the following day the patient complained of numbness of the foot and toes and tingling in the leg, and it was then noted that pulsation in the tibial arteries was absent. A diagnosis of rupture of the popliteal artery was made by Mr. R. C. B. Ledlie, who decided to operate. The artery was exposed and a large quantity of blood clot was evacuated from the popliteal fossa. No muscle bruising was evident, but the muscles and other soft parts in the region appeared to be infiltrated with blood, the latter having percolated for some distance upwards into the thigh and downwards into the leg. The artery was partially ruptured about half an inch distal to the hiatus in the adductor magnus. The vein was intact ; no nerve lesion was detected. The artery was ligatured above and below the rupture, the vein being left unligatured. The wound was then closed and drainage-tubes inserted.

This palliative operation was performed some 30 hours after the accident. The following day, that is, on the third day following the injury, evidence of incipient gangrene began to appear, and amputation was decided upon. This was carried out through the junction of the upper and middle thirds of the femur.

The patient made an uneventful recovery, and was seen about one year later, walking well, with a pylon attachment to the stump.

ÆTIOLOGY

In cases of ruptured popliteal artery associated with gross lesions in the region of the knee—e.g., fractures, dislocations, and those due to a crushing violence, such as occur when the limb is run over—the cause of the rupture is usually obvious. Schultz,[1] in his excellent review of 45 cases, gives an analysis of causes, and in his series there were 11 due to various forms of crushing violence, 11 due to luxation of knee, 5 due to fracture at lower end of femur, and 1 other referred to below. Harrison Cripps [2] records an interesting case in which a man had his leg pushed along in front of a braked wheel, which did not pass over the limb, and remarks that "the mechanism of rupture would appear to be the result of a force acting in an oblique direction, from below upwards, on the lower part of the femur." The artery gave way to find that it does not prevent the occurrence of middle-ear disease and mastoiditis or adenitis, though their incidence is reduced somewhat.

I think you will agree that the successful results obtained in immunisation against scarlet fever are remarkable in view of the impossibility of standardising the toxin or isolating a specific organism. The hæmolytic streptococci appear to be elusive and protean in character, and are responsible for many evils besides scarlet fever and its various complications, and it does not seem possible to sort them out satisfactorily.

I shall say little about the remaining infectious fevers as no recent discoveries have been made in connexion with them.

Measles

The micro-organism for this disease has not yet been isolated. Serum, however, from individuals convalescent from measles has been used successfully for the temporary immunisation of young children exposed to infection. This is of service in preventing the spread of the disease in hospitals and institutions, and for protecting infants and very young children in the case of whom an attack of measles might prove serious. The serum should be given before the sixth day of incubation to be effective.

Whooping-cough

Drs. Bordet and Gengou, working at the Pasteur Institute, isolated the bacillus of whooping-cough in 1906, which they cultured on a special medium of extract of potato and agar-agar with citrated or defibrinated blood. Various authors have confirmed their findings. Drs. Lawson and Mueller[12] isolated the bacillus in 259 out of 1115 cases examined, including 23 cases in the catarrhal stage. They found that there were two effective ways of obtaining cultures: by insulating Bordet-Gengou plates with pellets of sputum expectorated; and by holding a culture plate in front of a patient during a paroxysm of coughing. They claimed that vaccine treatment instituted early in the incubation period would often protect the patient. This, however, is a difficult matter to prove and has not been confirmed. Drs. Saure and Hambrecht[13] claimed that in a series of 200 cases they isolated the organism in 52 out of 53 cases in the catarrhal stage, and in 70 in the paroxysmal stage, but never in the declining stage. They considered that identification of the bacillus in the catarrhal stage was valuable as a means of early diagnosis for purposes of isolation.

Chicken-pox

Nothing definite is known as to the causative organism of chicken-pox, and the only point of interest which arises is that of the association of herpes zoster with chicken-pox.

In 1917 Le Feuvre wrote a paper[14] on "A plea for the common origin of shingles and chicken-pox." He collected 50 cases in which the two conditions were associated, which he classified under three headings: chicken-pox in one individual contracted from contact with shingles in another; shingles contracted from contact with a case of chicken-pox; shingles and chicken-pox occurring together in one individual. Of the 50 cases 41 came under the first heading, 5 under the second, and 4 under the third. The most common occurrence was the development of chicken-pox in a child following contact with shingles in an adult. The incubation period corresponded with that of chicken-pox. Dr. James Taylor[15] referred to Le Feuvre's paper, and quoted cases in which chicken-pox followed contact with herpes, and in a later paper[16] stated that since he had raised the question, several medical men had sent in accounts of similar cases. Personally, I have come across two cases falling under the third heading, in which a well-marked attack of herpes was followed in two or three days by chicken-pox in the same individual. Of course, the association of the two diseases is the exception rather than the rule, but it is interesting to find so many cases on record.

Conclusion

I have endeavoured to trace the great advance in our knowledge of the problems of immunity in connexion with diphtheria and scarlet fever. As regards the former, the success has been such that it would be possible to eradicate the disease from the country by the prophylactic measures now at our command.

As regards scarlet fever, universal immunisation, in the present state of our knowledge, is not a practical proposition, but such success has already been attained in the protection of those exposed to infection in fever hospitals that it may be feasible in the near future. Scarlet fever, however, is not so widespread as diphtheria, and if only a serum can be produced as efficacious in preventing its disastrous complications, as in the case of diphtheria, the need is not so pressing, though an enormous saving of expense to the taxpayers by the abolition of fever hospitals as well as great benefit to the public might be attained by the elimination of diphtheria and scarlet fever.

One word of warning. If these diseases are abolished as the result of what one may term "artificial" immunisation, this must be maintained indefinitely. At the present time natural immunity is to a great extent conferred on the community by droplet infection or mild doses of virus from "carriers" or patients, so that the "herd" are more or less salted. If all Nature's measures for protecting the community are withdrawn, and infection is introduced into an entirely unprotected community, a colossal epidemic might follow.

NEW SCHEME TO HELP HOSPITALS.—It is stated that the British Charities Association has given its approval to a new scheme for raising money for hospitals, and has expressed a hope that it will be well supported. Manufacturers are being asked to contribute to a central hospital fund one farthing for every pound sterling of their net sales, and it is suggested that the total sum thus obtained will be sufficient to solve the financial problem of the hospitals. The manufacturers would undertake not to increase the price of their goods, which would, where practicable, be marked with the words "Pledged support," and buyers would be asked to give preference to such goods. It is stated that many firms have promised their support to the scheme. It is proposed that a national hospital committee should supply participators with a distinctive emblem which could be used in advertisements.

from injury to vessels in any part of the body, has only been recorded twice.

From the above account of the very definite signs of rupture of this vessel, one would have thought that diagnosis of the condition should be relatively easy, and it is somewhat surprising to find that in most of the cases recorded, the diagnosis was not definitely established until the onset of gangrene, this usually taking place three or four days after the original injury.

Presumably this is partly due to the fact that the condition is so rare that the possibility of its occurrence does not enter the mind of the practitioner when he first sees the case. Moynihan has referred to the same diagnostic failing in the medical mind in connexion with another rare condition—acute *pancreatitis*—which. he says, is usually missed "because it has not been thought of." Like rupture of the popliteal artery, once the possibility of the lesion is seriously considered on logical lines the diagnosis is a long way towards being established.

Nevertheless, when one or other of the more salient diagnostic features are lacking, as is sometimes the case, the problem is rendered more difficult. For example, in the case recorded by Meyer [6] the most striking sign of pronounced swelling in the popliteal region was absent.

FIG. 1

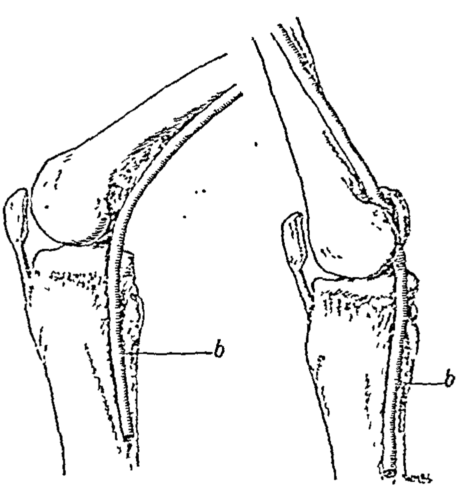

FIG. 2

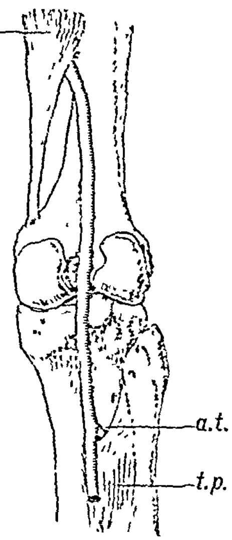

FIG. 1.—The popliteal artery in side view illustrating its relations to the skeleton: A, in slight flexion; B, in hyper-extension (abnormal) of the knee-joint. *b*, terminal bifurcation of the popliteal artery.

FIG. 2.—The popliteal artery from behind, illustrating the structures which are concerned in the fixation of its two extremities. *a.m.*, adductor magnus muscle; *a.t.*, origin of anterior tibial artery; *t.p.*, tibialis posticus muscle.

When the site of lesion was examined after operation only three or four spoonfuls of blood were present in the *Kniekehle*, yet both artery and vein were completely ruptured about 2 cm. distal to the hiatus in the adductor magnus. Both vessels were closed by a thrombus about 2 cm. long. The central end of the artery was very contracted and conical in shape. The injury was thought to be simply a "crushing wound" of the knee region without complications, the coldness and numbness being attributed to pressure on the tibial nerve. Failure of the pulse on the second day was also not regarded as significant and this was also the case in most of the other instances recorded. In a word of counsel Meyer says that in a case of relatively slight injury in the region of the knee where there is numbness and cold feet, always think of rupture of the popliteal artery—but do not forget the possibility of diabetes mellitus.

Billroth [8] describes a case similar to the above, in which the artery was ruptured when the lower end of the femur was fractured by a stone. The skin was insensitive as high as the knee, and the superficial veins were engorged with blood, the diagnosis being established on this latter fact, a point worth recording.

In the case of partial rupture, the diagnosis is often more difficult as pulsation in the more distal vessels is not always absent. The persistence of pulsation and a murmur heard over the fresh hæmatoma may be regarded as diagnostic features of partial rupture.

TREATMENT

In this, as in many other surgical conditions, the prognosis depends largely upon the rapidity with which the diagnosis is established and the proper treatment instituted. It would appear that tying the artery does not prevent the onset of gangrene, and Meyer even goes the length of saying that in the case of *total rupture* of the popliteal artery, it is impossible to save the damaged leg. Schulz states that "a rapid decision to amputate is in the best interest of the patient."

Apart from the empirical occasions for the above statement, it would appear upon consideration of the mechanism of the condition that they are what one would expect.

After the injury bleeding from the vessel soon ceases as a result of various factors. Considerable shock lowers the systemic blood pressure. The muscle wall of the vessel contracts (especially the circular layer after the rupture of the longitudinal clot) and consequently the vessel tends to close and thus diminishes the bleeding. A clot *rapidly forms* at the site of the rupture. Furthermore, the effused blood is limited in its spread by the fat and muscles in the region, and therefore the hæmatoma soon attains its maximum size. All these factors tend to bring about such a rapid equalisation of pressure inside and outside the vessel that the hæmorrhage ceases.

Local operative interference therefore, if undertaken, should not be with a view to tying the vessel primarily, but rather in an attempt to improve local conditions with a view to the facilitation of the establishment of an adequate collateral circulation. The latter is prevented in the limb after the injury by the following factors :—

(*a*) Pressure of the blood clot on the collateral vessels which would normally carry the blood when the main vessel was occluded.

(*b*) Damage to the associated soft parts.

(*c*) Damage to the smaller vessels themselves at the same time as the large artery and due to the same cause.

Factor (*a*) is, of course, most potent in hindering the establishment of efficient collateral circulation, and consequently evacuation of the clot by operation is manifestly a step in the right direction. Factors (*b*) and (*c*) however, are also important in this relation, and can be but little improved by operative interference. Factor (*b*) may be considerable. Poland [9] found the internal head of gastrocnemius torn. In many other cases the nerve was also almost torn through.

In view of the above facts, it is evident that once the condition is diagnosed tight bandaging, which just above the origin of the anterior tibial branch. Pozzi,[3] of Paris, has drawn attention to the frequency of rupture of an artery just above the site of origin of one of its large branches, the latter apparently acting as fixing agents, presumably in a manner similar to that of guy ropes.

When cases in which indirect trauma is the cause are considered, the problem becomes increasingly obscure. Such cases can, however, be classified into two groups—those in which the mechanical explanation offered seems adequate or, at any rate, likely, and those in which any explanation offered must of necessity be largely hypothetical.

The chief interest of the two cases we record above is that they fall into the second category. Adams[4] records a typical case which was accompanied by a slight luxation only of the lower end of the femur backwards, easily reduced by gentle manipulation—yet the artery was completely ruptured. In Schulz's series[1] three cases of rupture were due to forcible extension of a partly flexed knee-joint in which all the soft parts were contracted as a result of previous inflammatory changes in the region. A number of cases are also known in which this disaster has occurred in the course of enthusiastic but misguided "mobilising" of stiff arthritic joints. In all cases, of course, an unhealthy arterio-sclerotic condition of the vessel wall will obviously predispose to rupture.

We now come to the more obscure group of cases in which the rupture of the vessel is in itself the paramount lesion, and there is no evidence of other injury in the region. In connexion with these it will be profitable first to consider some points in the anatomy of the popliteal artery (Fig. 1).

Anatomical relations render this artery peculiarly susceptible to injury either by contusing or by twisting and stretching forces. The vessels in the popliteal space are in intimate relation to bone, more particularly when the knee is fully extended or hyper-extended (abnormally) (Fig. 1, A and B). Proximally the popliteal artery and vein are fixed at the adductor hiatus by the adductor magnus tendinous arch. Distally, at the terminal bifurcation of the popliteal artery, these vessels are anchored to some extent by the tendinous arch of the soleus, but chiefly by the tendinous arch of the tibialis posticus muscle, which together with the interosseous membrane through which it passes fixes the commencement of the anterior tibial artery (Fig. 2). The fact that the artery and vein are intimately associated in a common sheath in this region is also important, the two vessels frequently being ruptured together. Thus the anatomical proximity of the popliteal artery to the posterior surface of the femur and its proximal and distal fixations are the latent anatomical factors which tend to explain its subcutaneous vascular rupture, the result of a severe contusing injury without an associated bone lesion.

In cases where there is no evidence of a contusing force in the region, the above factors also play a part. Our cases quoted above fall into this category, and Mr. J. L. Stretton, of Kidderminster, also tells us of a similar case in his practice. A young lad suffered this injury during a game of football, yet he could not recall having been kicked in the region, nor could any sign of bruising be detected. Presumably, here again, a sudden hyper-extension at the knee-joint was a factor of great importance.

As a rule, the suddenness of the applied violence or movement induces a marked tension and distension of the vessel wall. In the popliteal artery the elastic tissue of the vessel wall offers but little protection against injury from sudden violence. The maximum tensibility of the vessel wall may not be reached, but the vessel, owing to its natural anatomical fixation, is ruptured by the abruptness of the violence to which it is subjected. Lipshutz,[5] who has pointed out some of the facts set out above, compares the mechanism of the vascular wound to a similar sequence of circumstances in the case of a taut piece of string. If the latter be firmly fixed at either end, then a sudden pressure or pull applied to its middle will cause it to give way.

An anomalous tendon, which may act as an additional factor in the fixation of the vessels, has been described in the popliteal region. The tendon has its origin from the short head of the biceps muscle and is inserted in a fan-shaped fashion into the postero-medial aspect of the capsule of the knee-joint, thus forming an additional arch over the vessels. As Lipshutz remarks, it must be admitted that this is an uncommon finding, but on the other hand, rupture of the popliteal artery is also relatively rare.

It will be gathered that the mechanism of rupture must be inferred from the known factors which we are enumerating. Two further points are worthy of consideration.

When the leg is extended to the normal degree the popliteal vessels do not rest against the bony surface, and consequently we can understand why they may be ruptured when the knee is over-extended (as in the case of anterior dislocation of the tibia—vide Fig. 1 B). Also in view of the firm fixation of the vessels anatomically, the rotation which takes place in the final locking of the knee-joint may presumably play some part in producing a torsion of the vessel when the joint is over-extended. This combined twisting and stretching of the vessel would together be very conducive to rupture.

DIAGNOSIS

In almost all cases, immediately or shortly after the injury, the patient complains of extreme pain, and a feeling of distension in the region of the knee (as if the leg felt too small). A swelling appears behind the knee, becomes stony hard, and gradually spreads upwards and downwards from the popliteal region. In some cases, according to Meyer,[6] the leg may swell to two or even three times its normal size. This, of course, is manifestly due to blood percolating downwards between the muscle layers.

Within a few hours the patient complains of a sensation of pins-and-needles first in the leg, then in the foot, and finally in the toes. Gradually, a numbed "dead" feeling is experienced in the foot, and localisation of sensation becomes more and more vague. Eventually, there is loss of all sensation as far as the middle of the leg.

In the case of complete rupture of the vessel, loss of pulsation in the anterior and posterior tibial arteries is an early sign. In cases of partial rupture, weak pulsation is usually still felt in the tibial vessels.

Rarely pulsation may be evident in the popliteal hæmatoma, and in the case of partial rupture, a pulsation murmur may be heard at the site of the lesion. This is said to be diagnostic of partial rupture, but these signs are not of much practical value, as they have only been noted on rare occasions. In 34 recorded cases pulsation was observed twice and a murmur was heard in one case only. Wahl[7] describes a remarkable case of rupture of both artery and vein in which a cross-anastomosis was established between the two vessels. The blood from the proximal part of the popliteal artery passed into the distal part of the severed vein with the result that a sort of reversed circulation was maintained for a time. Such an extraordinary occurrence, resulting recorded and is somewhat difficult to explain. The age at which it appears suggests some relation to the menopause.

The blood pressure curve for the eclamptic group rises much more rapidly after the age of 30, as compared with the control cases; the menopausal drop is exaggerated; there is a rapid rise up to 187 mm. and a slight fall, probably due to elimination, by serious disability or death, of the worst cases, which would have brought up the average still higher.

As there appears to be a difference of opinion as to what is to be regarded as the maximum normal systolic pressure, that indicated by Hill (140) has been accepted. On this basis 42·5 per cent. of eclamptics and 33·72 per cent. of controls have now got hypertension. On the control curve, however, the average systolic pressure rises to a maximum of 150 mm., and if this is taken as a standard, 26·5 per cent. of eclampsia patients and 21·6 per cent. of controls have hypertension. (Table I.)

TABLE I

Blood pressure.		Eclampsia.		Controls.
Over 140	..	40 = 42·5 per cent.	..	74 = 33·72 per cent.
„ 145	..	33 = 35·1 „	..	63 = 28·8 „
„ 150	..	25 = 26·5 „	..	47 = 21·6 „

Whichever standard is accepted a higher percentage of eclampsia cases is found to have hypertension.

The question arises as to whether the blood pressure gets progressively higher in relation to the time which has elapsed since the eclamptic convulsions, and in order to answer this, the average systolic blood pressure has been calculated in all the age-groups, in relation to the time since the attack.

All the age-groups show the same characteristics, such as a high reading in the 0–5 years section; a high jump between the second and third sections, and a low level in the "16 and over" group. This last is probably explained by two factors: (1) in the case of the eclamptics by death of the worst case; (2) in both classes by reluctance on the part of patients suffering from severe disability resulting from high blood pressure to come up for examination. (Table II.)

TABLE II.—*Average Systolic Blood Pressure*

Years since pregnancy.	Age-group.							
	31–35.		36–40.		41–45.		46–50.	
	E.	Ct.	E.	Ct.	E.	Ct.	E.	Ct.
0–5 ..	134	122	149	129	140	137	185	—
6–10 ..	135	141	139	142	—	143	138	158
11–15 ..	—	140	156	146	204	152	189	150
16 and over	126	130	166	128	159	144	133	126

E. = eclampsia; Ct. = control.

From Table II. one concludes that there is a fairly definite indication (after an initial drop) of a rise in blood pressure as time elapses after the attack. The fall in pressure between the fifth and the tenth years after the attack seems to suggest temporary recovery.

An attempt was made to determine whether *further* pregnancies have any effect on subsequent pressure readings. In the case of the controls there is no upward tendency as a result of further pregnancies, including miscarriages. Two groups of the eclamptics show a slight tendency to increase, but in two other groups the observations are indefinite. The early death of the worst cases makes these figures show to advantage, and there is thus a slight indication of rise of pressure with further pregnancies.

Inquiry was made into the relation between the number of fits and the pressure records, but the results were indecisive.

EVIDENCE OF RENAL DAMAGE

Difficulty was experienced in interpreting some of the findings. Where granular casts occurred in the urine of a patient with hypertension, it seemed reasonable to make a diagnosis of chronic nephritis.

Headaches were complained of in 24·4 per cent. of eclamptics and 10·09 per cent. of controls (a proportion of 2·4 : 1).

In 12·7 per cent. of eclamptics and 5·69 per cent. of controls (proportion 2·2 : 1) there was complaint of occasional œdema of the feet.

In the group of eclamptics albumin was present in the urine of six patients (6·38 per cent.). Two women appear to be definite cases of chronic nephritis.

One, aged 55, had eclampsia 16 years ago, in her eighth pregnancy. Two years later she had albuminuria of pregnancy, and was delivered of a stillborn, full-time child. When examined recently she was found to have a blood pressure of 230 mm. She complained of swelling of her ankles and hands; both 0·05 per cent. albumin and granular casts were found in her urine.

The other, a woman of 46, had eclampsia five years ago, in her sixth and last pregnancy. When seen her blood pressure was 240/160, the blood non-protein nitrogen 50 mg., and her urine contained 0·05 per cent. albumin—though no casts were found.

Two other patients, with neither casts nor albuminuria, gave suggestive histories.

The first, aged 38, had eclamptic fits in her first pregnancy, 16 years ago. She was found to have a blood pressure of 188/118, and her blood non-protein nitrogen was 31·4 mg.; she had œdema of the legs and ankles, and has been treated several times since her eclampsia for "kidney trouble."

The other, aged 36, had eclampsia in 1926, when pregnant for the fourth time; she had antepartum hæmorrhage with albuminuria in 1929, and acute nephritis in 1930. When examined, her blood pressure was 200/120, and she complained of œdema of the face and hands. It seems highly probable that the acute nephritis in 1930 was an exacerbation of a chronic condition.

Of the controls, albumin was found in two cases (0·91 per cent.), and in one of these, a woman of 48, the blood pressure was 238/156. This patient had typhoid fever 19 years previously, and according to Thayer,[11] the incidence of arterio-sclerosis is much higher after typhoid fever than in individuals who have not been affected. This may account for the high blood pressure in this case. These observations are set forth in Table III.

TABLE III

	Hyper-tension.	Albuminuria.	Prob. chronic nephritis.
	Per cent.		
Eclampsia ..	35·1	6·38	4·29
Controls ..	28·8	0·91	? Nil.

Two further cases are examples of eclampsia occurring in women with pre-existing chronic nephritis.

One, aged 47, gave a history of having had nephritis at the age of 7. There is no record of her first pregnancy; she had eclampsia in her second, and albuminuria occurred in each of the subsequent five pregnancies. When examined, her blood pressure was 168 mm., but no albumin or casts were found in her urine.

A second, aged 50, who had scarlet fever as a child, was traced through the courtesy of her doctor, but was unable to attend. She was treated for chronic Bright's disease after her second and during her third and fourth pregnancies, which ended prematurely. No information is available about the fifth; she had eclampsia in her sixth pregnancy, ars later, but is still alive.

would obviously embarrass the circulation still further, should be avoided.

The experience of some would seem to warrant local operation if diagnosis is made soon after the injury. The clot should be cleared out and the vessel ligatured. In most cases the vein is also damaged, but should this vessel be intact, it is advisable to ligature it as well, as by this means equilibration of the circulation seems to be brought about more rapidly. Albrot,[10] in 11 cases which he records, claims to have avoided gangrene in 5; Klein,[11] in a case of rupture of both artery and vein, avoided gangrene by ligature of both. If diagnosis is made later the best course to adopt seems to be to await the formation of a line of demarcation of gangrene, and then to perform amputation through the middle third of the thigh. The prognosis of partial rupture is, of course, more favourable, but there appears to be no case recorded in which suture in continuity has been successfully carried out.

We wish to thank Miss Mary Barclay-Smith for her illustrations and Mr. Ledlie for allowing us to report Case 2, which was under his care.

AN INQUIRY INTO THE

AFTER-EFFECTS OF ECLAMPSIA

WITH SPECIAL REFERENCE TO HYPERTENSION AND CHRONIC NEPHRITIS

BY JANET BREAKEY, M.D. SHEFF.

ASSISTANT PHYSIOLOGIST, JESSOP HOSPITAL FOR WOMEN, SHEFFIELD

MUCH has lately been written about the after-effects of eclampsia. Most observers have noted the liability to subsequent chronic nephritis, though they differ as to its incidence.

Harris[1] examined 27 women one year after an eclamptic attack and found chronic nephritis in 3. Nevermann[2] found the condition in only 3 out of 60 patients, though 30 others showed various symptoms, such as headache, visual disturbances, hypertension, &c.

Greenhill[3] also traced 60 "post-eclamptics," of whom 2 had died of nephritis, and 3 had this complaint when seen.

Döderlein[4] had only 1 case of hypertension in a series of 26 cases; 3 had slight albuminuria, and 7 albumin and casts.

Sym[5] examined 74 cases and found chronic nephritis in 2; Caldwell and Lyle[6] found nephritis in 8 per cent. of women after eclampsia, while Gibson[7] found the condition in 5 out of 14 patients.

It is difficult to compare results and draw conclusions without having a standard, and it was held desirable to control the results by following-up a number of women who had had eclampsia, and comparing the findings with those in normal parous women of corresponding parity and age.

Method of Inquiry

A review has been made of cases receiving in-patient treatment at the Jessop Hospital for Women, Sheffield, during the years 1908–1928 inclusive. These cases examined have been divided into two groups: (1) eclamptic patients who had definite fits; and (2) normal women as controls.

During the 21 years in question 333 cases of eclampsia were treated, with a mortality of 72 (21·32 per cent.). Of the surviving 261 patients, 10 were unmarried, and no attempt was made to communicate with them. Thus there remained for investigation 251 patients, of whom 94 attended for examination. A further 6 replied but were unable, for various reasons, to attend. Another 15 were not seen, but were traced through the courtesy of their family doctors, who reported on their condition; of these 7 had died. Four further deaths have been traced, making 11 altogether. Thus 132 were untraceable.

The controls were women without toxæmia, but who were as nearly as possible—as regards age, parity, and even method and date of delivery—similar to those of the eclamptic group who had attended for examination. Over 1300 women in this group were written to, and 218 attended. Seven are know to have died.

Method of examination.—Inquiry was made as to the patient's health and further pregnancies since the eclamptic convulsions or normal delivery as the case might be. In all cases both the systolic and diastolic blood pressure readings were taken whilst seated, due precautions being taken to eliminate a rise of blood pressure from emotional causes. The urine was examined, a catheter specimen being taken whenever albumin was found.

Results

Of the 11 eclamptic patients known to have died (at an average age of 34) after discharge from hospital, 1 was transferred to another institution with mania and died nine days later from pneumonia. A second was transferred four weeks after delivery to another hospital, where she died of broncho-pneumonia. Of the remaining 9, 4 died of nephritis, 1 of "dropsy" within four years, and 1 of perforated gastric ulcer. Another died of pneumococcal peritonitis five years later, but, since post-mortem examination revealed small white kidneys, she evidently had chronic nephritis. Two were certified as having died from "heart disease," death occurring respectively one year and seven years after leaving hospital.

Of the controls 7 are known to have died—at the average age of 63; 4 died from conditions in no way referable to renal disease. In the other 3 cases it was impossible to trace the cause of death.

ANALYSIS OF BLOOD PRESSURE READINGS

The average of both the systolic and diastolic blood pressures (at the time of examination) have been calculated for age-groups of five years—i.e., 20–25, 26–30, &c., and are shown in the Figure. Before we compare the results found in the two groups of cases it is necessary to consider the control curves. These show a general upward tendency between the ages of 20 and 60, with a slight, but definite, depression between the ages of 40 and 50. The upward tendency is in agreement with observations which have been made by various observers.

Taylor[8] states that in healthy persons the blood pressure increases from childhood to old age.

Leonard Hill[9] is of the opinion that the normal systolic pressure in healthy young men, measured by the digital method, is 110–130, but he also states[10] that this pressure should be as much as 10 mm. higher as measured by the auditory method, so that pressures up to 140 might presumably be considered normal.

The depression of blood pressure between the ages of 40 and 50 is an observation which one cannot find

The sequence may be represented as follows:—

Recurrence of eclampsia.—Twelve cases, of which two examples are given.

(1) Eclampsia. (2–7) Normal. (8) Eclampsia.
(1–5) Normal. (6) Eclampsia. (7) Eclampsia. (8) Abortion.

Eclampsia starting sequence.—Nine cases, of which two examples are given.

(1) Eclampsia. (2–4) Toxæmia. (5) Abortion. (6) Toxæmia.
(1–3) Normal. (4) Eclampsia. (5) Toxæmia.

Abortion-eclampsia sequence.—Ten cases, of which two examples are given.

(1–3) Normal. (4 and 5) Premature Birth. (6) Abortion. (7) Eclampsia.
(1–4) Normal. (5) Abortion. (6–14) Normal. (15 and 16) Abortions. (17) Eclampsia.

Conclusions

(1) In normal parous women there is a steady rise of blood pressure with increasing age, at any rate up to the age of 60. There is a slight depression between the ages of 40 and 50. After eclampsia the blood pressure rises more rapidly and to greater height. The depression occurs as on the control curve, but is exaggerated, and the readings at the upper end are modified by death of the worst cases. There is a fairly definite indication (after an initial drop) of a rise with advancing time; and a slight indication of a rise of blood pressure with further pregnancies.

(2) Chronic nephritis develops in a number of women after eclampsia, and this, in some cases, is severe enough to cause early death.

(3) There appears to be a direct relation between the age and parity of the patient, and the occurrence of hypertension and nephritis. Both are more liable to occur in multigravidæ who are over 30 at the time of the attack. Both occur more frequently after the antepartum type.

(4) There is no evidence that subsequent conception is rendered less likely by an attack of eclampsia. Fertility is lessened after this condition in that miscarriage and stillbirth occur more frequently than in normal women. Albuminuria is much more likely to complicate subsequent pregnancies after eclampsia than in normal cases.

(5) In a certain number of cases a "toxæmia sequence" occurs. Eclampsia may begin or end the sequence or may itself recur.

I am indebted to the staff of the Jessop Hospital for Women, Sheffield, for permission to use the case records of the hospital. I tender my grateful thanks to Prof. Miles H. Phillips and Mr. W. W. King for valuable assistance and advice, and also to Mr. J. R. Thompson, D.Sc., of the University of Sheffield, who has given me invaluable help with the statistical data available.

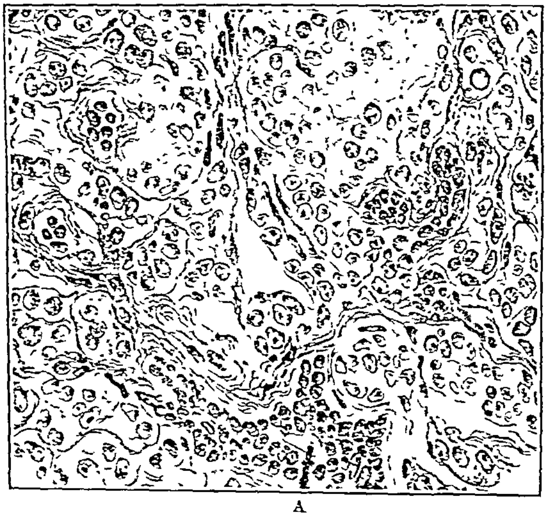
INFLUENCE OF THE SEXUAL CYCLE ON BREAST LESIONS

BY HELEN INGLEBY, M.B., M.R.C.P. LOND.
PROFESSOR OF PATHOLOGY IN THE WOMAN'S MEDICAL COLLEGE OF PENNSYLVANIA.

THOUGH a revolution in the interpretation of pathological lesions has followed Rosenberg's[1] discovery of the sexual cycle in the breast, even now the full extent and significance of these changes is sometimes scarcely realised. The proliferation of glandular elements during the premenstrual phase is far more rapid than the growth of a carcinoma. Their post-menstrual regression is equally astonishing; after a few days the only traces of the former lobule are one or two clefts barely visible in the fibrous tissue which has closed in and obliterated the site of the glandular mass. It is easy to see that even a slight upset in the mechanism of periodic growth and involution will have far-reaching consequences.

The most common benign tumour of the breast is known variously as fibro-adenoma, adeno-fibroma, and periductal fibroma. By comparing sections of breast and tumour from a series of cases in which the menstrual date was known it was found that in every one the tumour showed changes parallel to those in the surrounding normal breast. That is to say, in the premenstrual phase, new lobules formed in the tumour, although not as perfectly as in the breast; during menstruation the tumour ducts might be distended with secretion and shed cells; after menstruation many ducts underwent involution; in the interval phase the periductal fibrous tissue was dense and the epithelium had resumed the appearance typical of the resting state. The breast cycle was reflected in the tumour, but not perfectly. Had growth and regression been perfect there would have been no tumour. The tumour existed only because some local upset had marred the regular development

FIG. 1



Aged 33. Carcinomatous lobule from a breast removed 12 days before the onset of a period. The main duct (A) shows slight hyperplasia of the living cells but no cancer. It is surrounded by ductules; their outlines are still visible but in every one the epithelial cells are carcinomatous. This lobule was probably formed during the previous premenstrual phase but did not undergo involution since all its cells became cancerous.

On reviewing the known causes of death, together with the condition of patients seen, it becomes evident that chronic nephritis is found more frequently after eclampsia than in normal women. It is also clear that albuminuria and hypertension are more commonly found in the former group than in the latter. Christian and O'Hare [12] state that hypertension alone should not be considered evidence of chronic nephritis. After one examination it is frequently impossible to make a diagnosis between renal disease and hyperpiesia—the term applied by Allbutt [13] to hypertension associated with arterio-sclerosis. Arterio-sclerosis is commonly associated with intoxications and infections, and it seems possible that the eclamptic toxæmia may damage the kidneys or the arterial system or both.

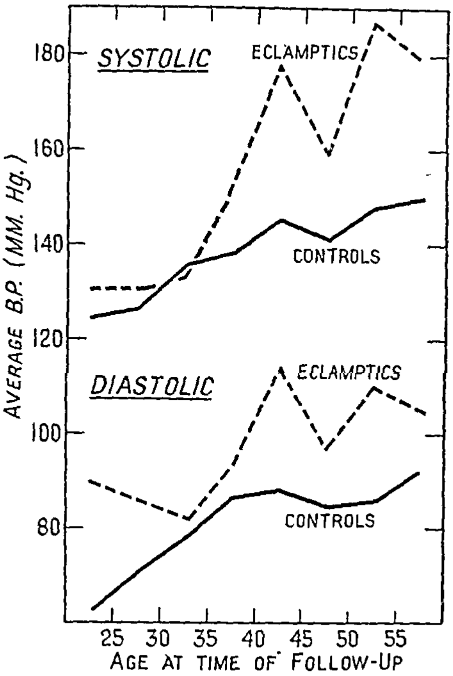

Chart showing the average blood pressure (systolic and diastolic) at various ages in women who have previously had eclampsia and those who have not.

TABLE IV.

Condition on examination	Condition at time of eclampsia.				Type.
	Under 30.	30 and over.	Primip.	Multip.	A.P. Eclamp.
Total —94	66 (70·2 %)	28 (29·8 %)	59 (62·7 %)	35 (37·3 %)	58 (61·7 %)
Nephritis —4	1 (25 %)	3 (75 %)	1 (25 %)	3 (75 %)	4 (100 %)
B.P. 160 and over —18	7 (38·9 %)	11 (61·1 %)	7 (38·9 %)	11 (61·1 %)	14 (77·7 %)
Nephritis at time of death —5	—	5 (100 %)	—	5 (100 %)	5 (100 %)

Peckham [14] has found in his series of cases that nephritis was present one year after an eclamptic attack, in 12·2 per cent. of primiparæ and in 39·3 per cent. of multiparæ. He also found age to be a predisposing factor, nephritis occurring in 11·8 per cent. of cases under 19, in 13·8 per cent. between 20 and 29, in 63·6 per cent. between 30 and 39, and in 66·6 per cent. over 40. Of "mild eclamptics" returning with nephritis, he found all in the antepartum group, while after the "severe type" the nephritics were distributed amongst the ante- and postpartum cases.

The findings discussed in this paper support those of Peckham. Of the five women who have died of nephritis, or who are known to have had it at the time of death, *all* were multigravidæ over 30 at the time of the attack, and in all the eclampsia was of the antepartum type. Of the four patients seen in whom chronic nephritis was diagnosed or suspected, three were multiparæ over 30 when they had eclampsia—which was antepartum in two cases and postpartum in the other two. Though at the time of examination a diagnosis of nephritis was made in only four cases, a further 18 women had a systolic pressure of 160 or over, and of these, 11 were over 30 years of age, and 11 were multiparæ when they had eclampsia, which was antepartum in 13.

These figures are very striking, for of the 94 women seen, 60 were under 30 and 28 were 30 or over when they had eclampsia, while 59 were primiparæ and 35 multiparæ. The antepartum type occurred in 58 (61·7 per cent.). (Table IV.)

SUBSEQUENT FERTILITY

In order to discover what, if any, effect these toxic conditions have on fertility, a careful history was taken of subsequent pregnancies in all cases seen. Pregnancy occurred again in 60·6 per cent. of women after having had eclampsia, and in 56 per cent. of normal women after the control pregnancy. Thus more eclamptics than controls actually became pregnant again.

Though ability to conceive does not appear to be lessened by an attack of eclampsia, miscarriages appeared to be common in this group, and the subsequent pregnancies have, therefore, been analysed. In the eclamptic group, miscarriages occurred in 22·8 per cent. of women, and of the controls in 15·5 per cent. In what proportion of women abortion was procured through fear of a repetition of the toxic condition is not known. (Table V.)

TABLE V

—	Eclampsia.	Control.
	Per cent.	
Reoccurrence of pregnancy	60·6	56·0
Miscarriage	22·8	15·5
Subsequent pregnancy complicated by albuminuria	8·5	0·46
Full-time pregnancy terminating in stillbirth	10·52	4·9

James Young [15] has drawn attention to the "surprising frequency of recurrence of toxæmia in eclamptic cases," and has noticed the existence of what he calls the "abortion-premature birth-toxæmia sequence." By piecing together previous and subsequent histories of all the cases traced, it has been possible to collect a number of cases in which such sequence occurs. Of cases traced a sequence is shown in 31. In 12 of these there is a recurrence of eclampsia, and five patients had normal pregnancies or abortions between the eclamptic attacks. One woman had eclampsia three times. In nine patients eclampsia started the sequence, being followed by abortion or toxæmia, and in six cases being preceded by normal pregnancies, while in the remaining ten cases, the sequence started with an abortion and went on to eclampsia.

(*b*) If only one or two ducts have become carcinomatous then the rest of the lobule undergoes the usual post-menstrual involution. The periductal fibrous tissue closes in. In the cancerous ductules the architecture is lost but the cells remain (Figs. 2 and 3). They remain as a column because of the pressure of the fibrous tissue outside. The column may be one or many depending on the number of ductules involved. Since cancer grows in the line of least resistance the cells are more likely to grow along clefts than in other directions. This accounts for the arrangement of cells in rows so often seen in carcinoma of the breast.

The observations recorded here were made from a study of six breasts from women ranging in age from 31 to 42. In none was the carcinoma complicated by other lesions. It is hoped to make cancer in older women the subject of a separate communication.

ON THE USE OF SANOCRYSIN IN PULMONARY TUBERCULOSIS

BY H. E. MANSELL, B.M. OXF., M.R.C.P. LOND.

MEDICAL REGISTRAR TO ST. GEORGE'S HOSPITAL

THIS paper is concerned with 153 tuberculous patients, who were treated with sanocrysin in Brompton Hospital during the three years 1926–28. Its publication is justified by the fact that, although the drug has been in clinical use for over seven years, there is yet no consensus of opinion as to its dosage, mode of action, and the type of case in which its use is indicated.

The patients were treated independently by the physicians under whose care they had been admitted. The obvious disadvantages of such separate observation have been more than counterbalanced by the fact that on some points the conclusions reached are similar and have thus received independent corroboration. The usual indication for sanocrysin was in patients not improving with conservative treatment and yet unsuitable for collapse therapy. It was also used in conjunction with artificial pneumothorax, phrenic avulsion, and thoracoplasty.

CLASSIFICATION OF CASES

It has been claimed that sanocrysin is more effective in the recent exudative type of case than in the fibrotic, and in order to investigate this point a fairly elaborate method of classifying the cases was considered essential. Of the available methods, that of Lyle Cummins[1] was adopted. He suggests a primary division of cases into two main types :—

1. Acute and initial (A), when the progress of the illness has been continuous from the start, without healthy intervals of any considerable duration.
2. Chronic and recrudescent (C), when there have been previous signs of tuberculous infection such as hæmoptysis, pleurisy, bone or joint or gland, abdominal or pulmonary infection, but where these have been separated from the present illness by periods of relatively good health. All cases over two years' standing are to be classified under this heading.

He subdivides each of these two main groups into three, using the international classification to denote the degree of lung involvement :—

1. Disease of slight severity limited to a small area of one lobe.
2. Disease of slight severity more extensive than (1), but affecting at most the volume of one lobe. Or disease of greater severity affecting at most the volume of half a lobe.
3. All cases of greater extent than (2), and all cases with considerable excavation.

For general purposes the stage should be assessed in accordance with the obvious clinical signs, but in this investigation the skiagraphic appearances have been taken into consideration, with the idea of obtaining a more accurate and more valuable assessment.

He makes a final subdivision according to the Inman method into (*a*) resting febrile; (*b*) resting afebrile, ambulant febrile; and (*c*) ambulant febrile.

It will be seen that by this method a classification consisting of 18 groups is obtained. The distribution of the 153 cases under discussion is given in Table I.

TABLE I

A1(*a*), A1(*b*), A1(*c*)	No cases.	C1(*a*)	1 case.
A2(*a*)	3 ,,	C1(*b*), C1(*c*), C2(*a*)	No cases.
A2(*b*)	2 ,,	C2(*b*)	1 case.
A2(*c*)	2 ,,	C2(*c*)	2 cases.
A3(*a*)	53 ,,	C3(*a*)	58 ,,
A3(*b*)	5 ,,	C3(*b*)	6 ,,
A3(*c*)	3 ,,	C3(*c*)	17 ,,

DOSAGE

During the early days large doses of sanocrysin were employed. It was usual to give an initial dose of 0·25 g. and end the course with three or more injections of 1 g. (in one case as many as seven injections of 1 g. were given). With added experience, however, it was unanimously found that each case must be considered individually on its merits, and there was a definite tendency to use smaller doses. Thus in 1926, out of 43 patients 22 received 6 g. or over, and of the remaining 21 more than half received 4 g. or over. In 1927 and 1928, out of 110 patients only 7 received 6 g. or over, and of the remaining 103 less than a third received 4 g. or over. Moreover, the first dose was usually only 0·05 or 0·1 g., and latterly it became the exception rather than the rule for final doses to exceed 0·5 or 0·75 g. The aim was to produce a moderate reaction and avoid strong reactions as far as possible. An interval of at least a week was allowed between injections, the total time taken to complete a course of 4 to 6 g. depending entirely on the degree of reaction produced and the subsequent spacing and increase rate of doses.

Two or more courses were given to 12 patients. This procedure appeared sound on theoretical grounds, and the results were encouraging. Ten cases showed improvement, three of them being "much improved." Of these, one showed improvement in symptoms and physical signs and, although a skiagram after the first course suggested an increase of infiltration, another taken after the second course showed marked improvement.

TABLE II

	Cases and per cent.
Temperature :—	
Evening rise (Type 2 of Secher[2]) ..	114 (74)
Delayed rise (Type 3)	2 (1⅓)
Sustained rise (Type 4)	6 (4)
Absence of temperature (Type 5)	31 (20)
Albuminuria	42 (27½)
Skin rashes	31 (20)
Affections of mucous membranes :—	
Conjunctivitis	2 (1⅓)
Metallic taste	18 (12)
Sore tongue	2 (1⅓)
Sore-throat	3 (2)
Stomatitis	3 (2)
Gastro-intestinal symptoms :—	
Vomiting	47 (31)
Diarrhœa	38 (25)
Abdominal pain	21 (13½)
Focal reaction	6 (4)

REACTIONS

The following reactions, similar to those recorded by previous writers, were noted as occurring after sanocrysin treatment (Table II.).

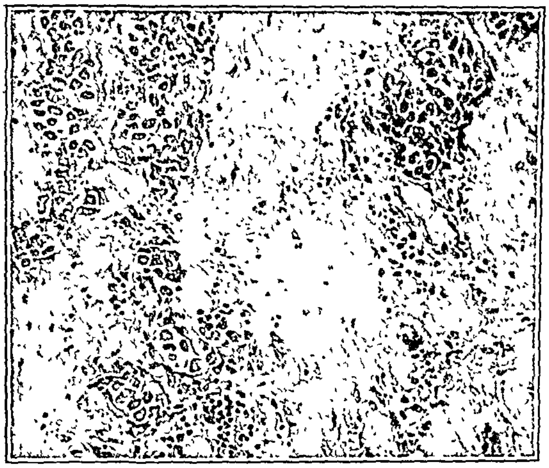
of the cycle. The varied appearances assumed by a fibro-adenoma depend upon which element or elements, epithelium or fibrous tissue, is at fault and in what direction (overgrowth, excessive secretion, defective involution, degeneration, &c.).

Just as fibro-adenoma is *the result of a local irregularity* in development and involution, so the lesion known as "chronic mastitis," or better, mazoplasia,* is the effect of a general irregularity in *the cycle* changes. The condition occurs most commonly in girls about puberty and in women *nearing the menopause, but is found particularly in* association with irregular menstruation in women of *any age. A similar condition can be produced in* rats by upsetting the œstrous cycle.

The lesions in fibro-adenoma and chronic mastitis have a direct relation to cycle changes. But even in carcinoma the sexual cycle cannot be left out of account. In women of the childbearing age it is of the utmost importance in explaining a common mode of spread of the growth and in accounting for some of its morphological appearances.

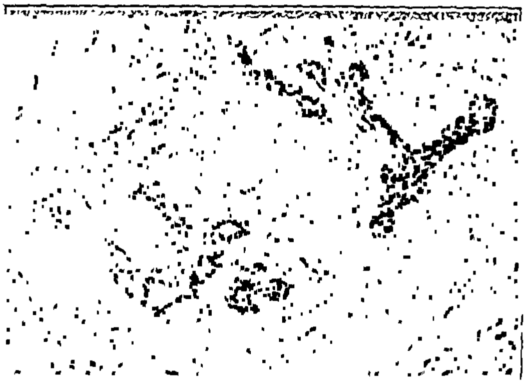
There is some substance given off by a carcinoma which induces hyperplasia in surrounding cells. For example, in the beginning stages of epithelioma of the skin it is common to find hyperplastic skin papillæ, showing early malignant change, at a distance from the main growth. In the breast, hyperplasia resembling that of the premenstrual phase is often seen in the neighbourhood of a malignant growth while the rest of the breast is in the resting stage. Not all hyperplastic tissues become malignant because, as F. S. Hammett and F. R. Reimann have shown, fully differentiated epithelial cells do not divide. Malignancy is only possible in those cells which for some reason do not differentiate fully. As regards squamous cell carcinoma it could be objected that the hyperplasia of adjacent skin going on to carcinomatous proliferation was not due to the presence of the primary growth but to the same factor that caused the original tumour. In the breast, however, I have shown that carcinoma in the main duct does induce carcinomatous proliferation in the cells of the lobules.[2] In breasts removed in the premenstrual phase, all stages from normal *premenstrual proliferation to carcinoma* can be traced in favourable sections in the newly formed lobules. The fact that the cells in the *main duct*, which are the result of many divisions, have in some cases *a totally different appearance* from the newly forming carcinoma cells in the lobules, shows that the growth in the lobules is not due to migration there of cancer cells from the main duct. The mode of spread by carcinomatous transformation of the newly formed cells of premenstrual lobules will explain why, in younger women especially, carcinomatous nodules are found scattered through a breast, as Cheatle showed many years ago, in the territory covered by an affected duct and its branches.

FIG. 2



Aged 36. Section taken near the edge of a carcinoma. Breast removed on the fourth day of menstruation. Groups and columns of cancer cells are seen surrounded by fibrous tissue. In the fibrous tissue are clefts, the remains of ductules which have undergone post-menstrual involution.

FIG. 3



Aged 36. Normal lobule from the same breast as Fig. 2. Post-menstrual involution is nearly complete. The ductules have disappeared except for the clefts which mark their site. Only the larger ducts remain.

Under the microscope most breast carcinomas bear no resemblance to the normal tissue, a fact which has puzzled generations of students. A study of what happens to cancer *during the sexual cycle* changes in the breast will show how some of the microscopical *appearances arise.*

When a premenstrual lobule comes under the influence of a carcinoma in one of the larger ducts it is possible either for the cells in the whole or the greater part of the lobule to be affected or for only one or two of the ductules to undergo carcinomatous change. The events in the first of these alternatives will be as follows: (*a*) The cancer cells in each ductule grow and divide. The lumen of the ductule is obliterated and its architecture soon lost. Of course no post-menstrual involution takes place in the carcinoma cells *and before long the periductal connective* tissue is encroached upon and destroyed. By *the time* the next premenstrual phase is due the outlines of the former ductules are barely distinguishable (see Fig. 1). Soon all that is seen is a round or ovoid clump of cancer cells occupying the former site of the lobule. But owing to the destruction of the connective tissue the blood-supply is cut off from the centre of the mass. The centre then degenerates and finally there is a clear central space *surrounded* by a ring of cancer cells. These are not ducts as has sometimes been supposed. They *are* lobules which have become carcinomatous "en masse" and whose *centres have degenerated.*

---

* Lenthal Cheatle uses the term "*mazoplasia*" to denote extreme physiological hyperplasia and desquamative cysto-phorous hyperplasia to denote the pathological condition. Mazoplasia has here a b[illegible] significance in that it includes cystic dilatation of ducts [illegible] proliferation which can be ascribed to the [illegible]

[2] Arch. of Pathol., 1929, viii., 653.

SANOCRYSIN WITH THORACOPLASTY

Five cases were treated with this combination. One case will not be considered in detail, because thoracoplasty was performed much later as treatment for a spontaneous pneumothorax that arose in the interval between two courses of sanocrysin; the treatments were in no sense used in conjunction. The value of this combination can best be indicated by a brief account of the other four cases.

No. 2, a man of 33, had a large right hydropneumothorax, the result of a spontaneous pneumothorax five weeks before, and scattered infiltration in the other lung. Temperature 101–102/98–99° F. After sanocrysin treatment his condition was greatly improved, sputum still positive, but evening temperature only occasionally rising to 99° F. He was then successfully operated upon by thoracoplasty, and his present condition, four years later, is good.

No. 11, a man of 39, was admitted with a right pyopneumothorax, which had arisen in an artificial pneumothorax initiated a year previously. The left lung showed no clinical or skiagraphic evidence of infiltration. The sputum was positive, and the evening temperature 100° F. As a result of sanocrysin treatment his general condition improved, evening temperature fell to 99° F., and the sputum became negative. Phrenic avulsion and thoracoplasty were then performed. Four years later he is alive, but has been bedridden for the last 12 months.

No. 96, a man of 29, was admitted with bilateral disease of considerable extent, sputum positive, and temperature 99·4° F. at night. Phrenic avulsion and thoracoplasty were performed on the left side, which was the more diseased of the two, and six weeks after the operation the patient had made an excellent recovery, the amount of sputum had been reduced from 2 oz. to ½ oz. daily, but the evening temperature of 99·4° F. persisted. A course of sanocrysin was given, after which he was able to go to Frimley afebrile and with negative sputum. He is now alive and in good health, two years afterwards.

No. 127, a widow of 39, was admitted with an evening temperature of 98·4–100° F. Clubbing was present, and the sputum was positive. A right artificial pneumothorax had been initiated eight months before, and X ray now showed the diaphragm on that side high and adherent, with much basal fibrosis but no fluid. Phrenic avulsion and thoracoplasty were performed, after which the temperature settled for a time, but two months after the operation it had risen again to 101·5° F., and X ray now showed scattered infiltration in the left upper and middle zones. Although the fever again showed signs of settling, a course of sanocrysin was given; after the second dose the sputum became negative and remained so, and she was eventually discharged to Frimley afebrile and gaining weight. She is now in good health, two years afterwards.

These cases suggest that sanocrysin has a value, either in preparing a patient for thoracoplasty or as treatment for the better side in cases of bilateral disease where the operation is performed on the worse side. It will be convenient to include under this heading a case in which sanocrysin was combined with phrenic avulsion for the latter purpose.

No. 104, a girl of 23, was admitted complaining of cough and loss of weight since broncho-pneumonia and pleurisy two years before. She was somewhat cyanosed, with slight clubbing of the fingers and an evening temperature of 99° F. She was found to have infiltration of the whole of her left lung, the base being especially involved, and infiltration of the upper and middle zones of the right lung. Left phrenic avulsion was followed by a reduction of sputum from an ounce to a drachm daily, but her general condition remained unaltered and she was unable to get up without rise of temperature. After a course of sanocrysin she was discharged to Frimley, afebrile and up for six hours daily, with negative sputum and a gain in weight of 10 lb. She is now alive and in very fair health, two and a half years afterwards.

AFTER-HISTORY

Of the total number of 153 patients, 142 (93 per cent.) have been successfully followed up, and only 11 could not be traced. In view, however, of the several uncontrollable factors involved, it was considered that nothing would be gained by a statistical examination of the after-histories of these patients.

DISCUSSION

This paper is in no wise an attempt to estimate the value of sanocrysin in pulmonary tuberculosis. The criteria to be observed in such a task have been admirably stated by Walters,[4] and include not only a similar group of control cases under similar conditions, but also a knowledge of how the remedy should be employed, how it acts, and under what conditions. Neither of these criteria was available, the first because the routine of a metropolitan hospital makes such control experimentation impracticable, and the second because the knowledge in question has yet to be discovered. Amberson and his fellow-workers [5] have set an example of the carefully pre-arranged plan to be followed in a clinical test of a chemotherapeutic agent, but their conclusions as to the undesirability of sanocrysin treatment cannot be accepted as final until the work has been repeated with different dosage and less advanced types of case. On these questions of dosage and type of case certain conclusions may be drawn from the present series of cases and from the published literature.

The dosage controversy reached its culmination, after seven years, in a recent issue of THE LANCET, when in consecutive papers Secher [6] advocated the large dosage, and Allon Pask [7] stated that he had discontinued using doses larger than 0·75 g. All workers are agreed that some degree of reaction to the drug is desirable, and reaction depends on two factors, the type and extent of the tuberculous process and the dosage of sanocrysin. The more severe the type of case, therefore, the smaller must be the dose if disastrous reactions are to be avoided. Examination of the results published by advocates of small doses reveals the fact that the cases treated were mostly of advanced type. Wurtzen and Sjørslev [8] treated 145 cases with small doses and found improvement in 88 (68 per cent., as compared with 67½ per cent. in the present series); the cases were of advanced type. Faber [9] compared the results of large and small dosage in two groups of cases and obtained better results with the latter; both groups consisted chiefly of Type II. and Type III. patients. In the present series smaller doses were gradually adopted, and the most striking fact which emerges from examination of the clinical material is that a very large proportion of the cases are classified as A3(*a*) or C3(*a*), while not a single case is to be found in classes A1(*a*), A1(*b*), A1(*c*), C1(*b*), C1(*c*), and C2(*a*).

On the other hand, Secher,[6] who adheres steadfastly to the larger doses and who claims "cure" in a considerable number of cases, states clearly that in his opinion "an advanced stage is a contra-indication to sanocrysin, as the patient will be unable to stand the intoxication produced by the treatment." He now reserves sanocrysin for cases where cure, or at any rate considerable improvement, can be anticipated. Stub-Christensen [3] found that large doses were as well tolerated as small by Stage I. patients. Case 1 in this series, who during his course received no less than seven injections of 1 g., was an early case with only eight months' history and afebrile at rest. He showed both symptomatic and skiagraphic improvement at the time of treatment, and five years later was well and working eight and a half hours a day.

Finally it should be noted that Amberson's [5] cases were all either moderately or far advanced, and that he employed a dosage which many would consider too large for the type of case, a fact which may explain his disappointing results.

What is the conclusion? Clinical evidence is accumulating to show that in cases of extensive exudative disease sanocrysin in small doses often has a beneficial immediate effect which may be at least of economic value. There is yet no convincing

Malaise lasting 24 hours or so was complained of in almost every case. Cramps and joint pains occurred in 11 cases, drowsiness in 20 cases, night-sweats in 5 cases, and rigors in 23 cases. Type 3 of temperature reaction was in both cases associated with the appearance of a rash. Type 4 was found in children, in patients destitute of resistance, and as the result of excessive dosage. Of the 31 cases in which Type 5 was encountered, 7 were acute and initial, and 24 were chronic and recrudescent. This distribution supports the view of previous observers that absence of temperature reaction is found in cases where fibrosis is the predominant pathological feature. When albuminuria occurred, it was considered inadvisable to give the next dose of sanocrysin until the urine was clear. The occurrence of a skin rash was not considered an indication to discontinue the treatment, provided that special care was taken with subsequent doses. In only one case was diarrhœa severe enough to necessitate abandonment of the treatment. Focal reaction took the form, subjectively, of pain and tightness in the chest, dyspnœa, and increased cough and sputum; objectively, of an increase in the number of râles.

IMMEDIATE RESULTS

In attempting to assess the immediate results of the treatment, I have taken four factors into consideration: (1) disappearance of bacilli from the sputum; (2) general symptomatic improvement as connoted by lowered temperature and pulse-rate, diminished or absent cough and sputum, absence of lassitude, improved appetite, and increasing weight; (3) changes in physical signs in the direction of fibrosis and diminution in the number and extent of moist sounds; (4) skiagraphic changes suggesting diminished infiltration and increase of fibrosis. Each patient has been marked in these four categories, a half or whole mark being given according to the degree of improvement. Maximum improvement would thus be denoted by +4. Patients showing only −½ or +½ have been regarded as unaffected by sanocrysin.

In 36 cases no record of the sputum findings was available, and 9 patients were negative throughout their stay in hospital. Of the remaining 108 cases with a positive sputum, 49 became negative during treatment, a bacillary loss of 45 per cent., which is comparable with the 43·9 per cent. given by Stub-Christensen[3] as the figure for his early period, when many unsuitable cases were included. In five cases the sputum became positive during treatment; in two of these it remained positive, while in three it became negative again before the end of the course. It was disappointing to find that the disappearance of bacilli was in a large number of cases not permanent. Thus, of the 49 cases who showed disappearance of bacilli during treatment, no less than 29 were known to have become positive again within three months, and probably there were others, as it was not found possible to follow up every case on [illegible] [illegible] this point.

TABLE III

	Cases and per cent.
Died	3 (2)
Worse	14 (8½)
Unchanged	31 (22)
Improved	78 (51½) } = 67½ per cent.
Much improved	24 (16) }

The general results are given in Table III. "Improved" denotes less than +3; "much improved," +3 or over.

The relative results in the two main groups of cases are given in Table IV.

—	Cases.	Died.	Worse.	Un-changed.	Im-proved.	Much im-proved.
		Cases and per cent.				
Group A	68	3 (4½)	5 (7½)	9 (13½)	32 (47)	19 (27½)
Group C	85	0	9 (10)	25 (30)	46 (54)	5 (6)

Group A, it will be seen, contributes a large proportion of the "much improved" cases, but also the only three cases who died during treatment. It may be noted here that of the 19 Group A patients classed as "much improved," 14 were 25 or under in age, and 10 of these were actually only 21 or under. Group C includes a relatively large number of unaffected patients, but also shows quite a high percentage of improvement if the total results are taken:—

Group A .. .. 51 improved = 74½ per cent.
" C .. .. 51 " = 60 "

These facts support the generally accepted view that dramatic results are more likely to be obtained in young patients with recent exudative disease, and that fibrotic cases, although apt to be unaffected by sanocrysin, do frequently show some improvement.

The relative results in 1926, when large doses were used, and in 1927–28, when more caution was employed, are given in Table V.

TABLE V

Year.	Cases.	Died.	Worse.	Un-changed.	Im-proved.	Much im-proved.
		Cases and per cent.				
1926 ..	43	0	5 (12)	12 (28)	19 (44)	7 (16)
1927–28.	110	3 (3)	9 (8)	22 (20)	59 (53½)	17 (15½)

The difference is not striking, but enough to warrant the use of small doses, at least in the severe type of case under discussion.

SANOCRYSIN AND ARTIFICIAL PNEUMOTHORAX

Several patients in this series at some time or another received collapse therapy as well as sanocrysin, but only those will be included here who were treated "de novo" with the combination. The combined method was used in 18 cases; in 11 of these collapse was induced on the worse side while gold was given for the other lung; in two cases treated in the first place with pneumothorax for unilateral disease, sanocrysin was given for fresh infiltration in the other lung; in two cases sanocrysin was combined with bilateral pneumothorax; and in three cases of unilateral disease collapse therapy was found to be insufficient and the combination was used. The results are given in Table VI.

TABLE VI

	Cases and per cent.
Worse	4 cases (22)
Unchanged	No "
Improved	10 " (56) } = 78 per cent.
Much improved ..	4 " (22) }

No final conclusion can be drawn from such a small number of cases, but the figures certainly lend some support to the view that sanocrysin is of value in conjunction with collapse therapy.

place, and now I am thankful to say I am cured. I have no pain in my feet; I can walk seven miles with ease and comfort; and I feel that a new lease of life has been granted to me." Now I take credit to myself that on receipt of that letter I realised that this was not an occasion for petty annoyance or for standing on my dignity. Here was a most typical case of one of the commonest complaints in orthopædic surgery, which I had treated. no doubt you will say, very badly, and I agree, but at least I will say conscientiously and according to the accepted principles of all the leading orthopædic surgeons of the day. Yet I had failed miserably, and the patient had gone to a bone-setter who had promptly cured her.

I sat down and I asked myself three questions. First, was this genuine? Yes, undoubtedly it was. I knew this patient well. and I had no doubt that, whatever the explanation, she had been relieved of her pain. Besides, we had heard of many similar cases where patients had failed to get relief from orthodox treatment and had then been cured by bone-setters. So my second question was: what is it possible for a man (any man) to do to a foot with his hands alone? The answer is that, apart from rubbing or massage (with which we are not now concerned), he can do nothing except *move* it. In what way, then. can one man's movement or manipulation differ from that of another? We had often manipulated feet, when we thought it was indicated, but we had not had the dramatic successes that were claimed by bone-setters. The answer to this is that he can only move it with more force, or in a *different direction. or both.*

Now here was the key to a riddle which had puzzled surgeons for many years, and, like all riddles when you know the answer, it is extremely simple.

The Secret of the Bone-setter

The human foot is always described as a structure built in the form of an arch, and it is commonly believed that this arch is maintained, at least in part, by the ligaments and fasciæ of the sole, and that when these give way the individual suffers from flat-foot. This is a half-truth which is little better than a lie. The truth is that the natural foot, as seen in bare-footed races who have never worn boots or shoes, is completely flat when its muscles are relaxed and arched only when the muscles are *in action.* You may observe the same thing in the feet of the best ballet-dancers; their feet also are completely flat when *standing at ease* and highly arched only when their powerful muscles are in action. You can see it also in the feet of your own children, when they are beginning to walk. In short, the natural foot should be so supple, it should have such mobility, that it can be completely *flattened or raised in the* form of an arch at will, and the attitude of the foot at any moment is determined by the action of its muscles.

Unfortunately, nearly all civilised people from early childhood onwards encase their feet in stiff leather coverings—boots or shoes—with the result that much of the natural mobility of the foot is lost and the feet become *fixed in* a position of action—that is, with more or less of a fixed longitudinal arch. The individual is then compelled for ever more to keep his body-weight raised above this minimum height of arch, for otherwise he will press it down and stretch and strain the soft parts which are shortened and adapted to the arch. There cannot be strain without resistance. If a foot can flatten completely without resistance, it is painless, and the completely flat-foot nearly always is painless. People do not suffer from flat-foot, but from inability to flatten their feet—that is, from foot strain.

For years and years both the medical profession and the public have been obsessed with the idea of putting up. restoring. and supporting the arch of the foot. It has been a miserable failure. I do not deny that a slight so-called support may give a measure of relief in some early cases of foot strain, but the relief is usually *short-lived. A rigid support* converts the would-be supple foot into a rigid system without spring, elasticity, or comfort. The bone-setter, on the other hand, to give him his due. tumbled to the fact that the right treatment of a strained *foot was to remove the resistance to flattening, to* restore or increase its mobility. so that it could yield and flatten without meeting resistance. Note, then, how his movement or manipulation differed from ours. We had used as much force as he used. We had even on occasions used a spanner, a thing called a Thomas's wrench, which gives enormous leverage and far more force than can be applied with the hands alone. But we had always tried to push up the arch of the foot and to mould it into what we thought was its natural shape. He manipulated in exactly the opposite direction, abducting, everting, and flattening out the sole to the utmost.

The proof of the pudding is in the eating. For many years now we have manipulated all cases of *foot strain,* which is miscalled *flat-foot.* We do it better than the bone-setter, because we employ full anæsthesia and so have complete control of the foot. We do it more safely, because we can make a differential diagnosis and we do not manipulate indiscriminately cases of foot strain, tuberculous joints, and feet that are stiff from chronic arthritis. The results are most gratifying. for the great majority of cases are promptly relieved of their pain and disability.

Perhaps I can hear some of you say, "flat-foot as we know it is a most unsightly deformity, with its turned-out feet and its ungainly walk. Do you really mean to tell us that you deliberately make these people more flat-footed than before?" No. I don't. You will find that when they are relieved of their pain and stiffness by manipulation they begin to use their muscles normally again. and I have told you that the attitude of the foot is but an expression of muscular action. Massage and exercises here play a part in the after-treatment. and in this respect also we have improved on the empirical treatment of the bone-setter. Again I say, this is not all specialists' work which has nothing to do with general practice. These cases abound in general practice, and it is work that anyone can do who cares to do it.

How are you to recognise these cases? That is easy. The patient complains of pain in his feet, they ache when he has been on them, and he gets so easily tired. The pain is referred typically to the inner border in the region of the astragalo-scaphoid joint; *commonly,* also, to the outer side below and in front of the external malleolus; and sometimes to the fore-part of the foot. The condition is brought on by prolonged standing or over-use of the feet. or as the result of muscular debility. as on getting up after an illness. There may be a history of injury—a twist or sprain—some time before. Such cases. of course. are often unilateral. Now stand the patient up and *look at his feet.* You will probably say that he has flat-foot. But do not be deceived by the eversion of the foot as a whole. Take hold of the foot in your evidence that this effect is lasting, in fact such a contingency is unlikely in the type of case under consideration. The following indications are suggested for its use :—

(1) In cases of active infiltration, where for any reason the time factor is important, it being reasonable to infer from these cases that the improvement shown in general condition, physical signs, and skiagraphic appearances would have taken longer to obtain by ordinary methods of treatment.

(2) In certain cases which remain pyrexial on exercise after three months' institutional treatment: (*a*) cases in which collapse therapy is impossible owing to adhesions or any other cause; (*b*) cases which have already been treated by artificial pneumothorax, phrenic avulsion, or thoracoplasty.

(3) In certain cases in conjunction with one of the forms of collapse therapy.

(4) In cases of extreme gravity, where all other treatment has proved unavailing, in view of the fact that results little short of miraculous have been recorded after its use.

The case for the use of large doses in treating the disease in its early stages remains unproven, and it is suggested that there is a real need now for further investigation of this question on the lines laid down by Amberson and his colleagues.[5]

SUMMARY

A review of 153 patients treated with sanocrysin shows that the most dramatic effect, in the direction either of improvement or the reverse, is obtained in young patients with exudative disease, and that fibrotic patients, although more likely to be unaffected, do in a considerable number of cases show definite improvement. Promising results are obtained from its use in conjunction with artificial pneumothorax, phrenic avulsion, and thoracoplasty. There is need for further controlled investigation, particularly of the effect of large doses on early cases showing a relatively slight degree of lung involvement.

My sincere thanks are due to the honorary medical and surgical staff of the Brompton Hospital for permission to use their cases in this investigation. It was carried out with the aid of a grant from the Hospital Research Fund.

HOME ACCIDENTS.—A "safety in the home" committee has been formed at Sheffield in consequence of the large number of indoor accidents, especially to children and old people. It is stated that whereas traffic accidents treated at Sheffield Royal Hospital are only 4 per cent. of the casualties treated, domestic accidents amount to 20 per cent.

REMEDIAL PHYSICAL TREATMENT AT KING'S COLLEGE HOSPITAL.—Last week Dr. Barrie Lambert, chairman of the public health committee of the London County Council, opened an extension of the physical treatment department of King's College Hospital. Lord Gorell, the chairman of the hospital, stated that in 1921 the number of patients in the department was 35,200; last year it was 60,500, and this year the number has increased to 110,000. The number of massage students has grown from 30 to 70, and in an examination open to all England, King's College students took first and third places. The new premises were formerly the students' refectory.

MANIPULATIVE SURGERY IN GENERAL PRACTICE*

BY A. S. BLUNDELL BANKART, M.CHIR. CAMB., F.R.C.S. ENG.

ORTHOPÆDIC SURGEON, MIDDLESEX HOSPITAL; SURGEON TO THE ROYAL NATIONAL ORTHOPÆDIC HOSPITAL

IT is now the fashion to speak of manipulative surgery, but the term has nothing to commend it. There is no conceivable reason why the simple procedure of moving a joint or joints for therapeutic purposes should be exalted into a special branch of surgery with a high-sounding title like "manipulative surgery." The term was invented, not by us, but by a bone-setter who, having achieved considerable popularity, decided to call himself a manipulative surgeon and thereby seek to attain to the higher status which such a name implies.

Manipulation is not a highly specialised branch of surgery with a difficult and mysterious technique which can be practised only by a few highly trained or specially gifted individuals. It is really the simplest thing in the world, if you only know, and it can be done by anyone who has two good strong hands and an inclination for minor surgery. It is done regularly by my young house surgeons and registrars as a part of their routine work. I do not deny that a certain facility in manipulation is acquired by practice and experience, but, after all, that is true of all manual procedures, whether at work or at play.

It is true that surgeons generally were slow to appreciate what might be done by manipulation in certain cases, and that the conspicuous success, not of one, but of many bone-setters was one of the factors which compelled their attention. But there were reasons, if not excuses, for this tardy recognition. In the first place, surgeons were very much preoccupied with the abdomen and the bigger things of surgery. Orthopædic surgery itself was not officially recognised as a specialty in this country until the year 1913, and then only under vigorous protest from many of the older surgeons. Moreover, the obviously false diagnosis of "a small bone out of joint," upon which the bone-setters' practice was ostensibly based, was calculated to prejudice surgeons against it, and to blind them to the good which might be achieved empirically. Lastly, a very large proportion of the cases regularly seen in orthopædic practice have previously been treated by bone-setters, so that orthopædic surgeons were perhaps unduly familiar with the unsuccessful side of manipulative surgery. For there is an unsuccessful side, and it is well to appreciate the limitations as well as the possibilities of manipulation in surgery.

Many years ago I received a letter from a patient of mine—an intelligent, educated, middle-aged woman. She reminded me that some two years previously she had consulted me for pain in her feet due to flat-foot. While under my treatment she had done everything that I had told her to do. She had worn the special boots that I had ordered, with the wedges and the supports. She had had the massage and done the exercises which I had prescribed for her. But she had got no better, and she began to fear that she would be crippled for life. Then she consulted a bone-setter. "He" she wrote; "he, with his wonderful hands, put the bones of my feet back into has been poured out, chiefly from America, about what Americans have called "low back pain." In my opinion the subject has been needlessly elaborated and a great deal of what has been written is purely imaginary. The cases included in this category fall mostly into four groups: (1) sacro-iliac strain; (2) lumbosacral strain; (3) acute and chronic lumbar back strain; and (4) spinal arthritis, with or without sciatica. In addition to these, of course, we meet with cases of true lumbago, Pott's disease, compression fractures of the lumbar vertebræ, and other less common conditions which are easily distinguished by their characteristic signs.

---

* A paper read at the Paddington Medical Society on Oct. 11th, 1932.

SACRO-ILIAC STRAIN

Strain of the sacro-iliac joint is the commonest cause of persistent pain in the lower part of the back. The sacro-iliac joint is exceedingly strong and possesses a very small range of normal movement, while the forces acting upon it are very great. If during some sudden or unguarded movement the joint is forced beyond its normal range, it is strained or sprained like any other joint in similar circumstances. Such strains are very common; but that any gross or demonstrable displacement or subluxation of this joint occurs, except in the rarest instances, has never been proved either by clinical or by radiographic examination. Sacro-iliac strain either comes on suddenly with a sharp pain in the joint during some effort or after a fall, or it may seem to come on gradually. Many patients who give a history of gradual onset will, however, recall a strain or an injury when they are questioned about one. It is especially common in women, and not infrequently follows childbirth or gynæcological operations. The patient complains of pain over the back of the sacro-iliac joint, usually worse after sitting and often better when he is walking about. He has a feeling of insecurity which is quite characteristic. When asked to localise the pain, he feels more or less accurately for the posterior superior spine of the ilium, which overlies the centre of the joint, and firm pressure over this point and immediately below it evokes an expression of pain, which is almost enough for a correct diagnosis. In fact, the only serious condition to be excluded is tuberculous disease of the sacro-iliac joint, which is comparatively rare, much more disabling, and seldom presents itself before there is either an abscess or obvious signs of bone destruction in the radiogram If this condition is not recognised and properly treated it may persist for years, and a considerable degree of neurosis is often developed.

The treatment is usually simple and straightforward. The great majority of cases (over 90 per cent.) are cured by manipulation, and occasionally the cure is sudden and dramatic. It is exceptional to find a case that obstinately resists manipulation, though some cases have to be manipulated more than once. The few that are not so cured can be cured by arthrodesis of the joint. The actual manipulation employed is a forcible twist of the pelvis under full anæsthesia, while the patient is turned half over, so that the leg on the affected side hangs over the side of the table. Massage and exercises are commenced on the following day and continued for a month, or as long as may be necessary.

LUMBOSACRAL STRAIN

Lumbosacral strain is quite different from sacro-iliac strain and should not be confused with it, even when, as sometimes happens, the two conditions are combined. As in sacro-iliac strain, there may be a history of inj [illegible] adual onset, and the latter history is usually associated with faulty posture. When the patient is asked to localise his pain, he draws his fingers horizontally across the back above the base of the sacrum. Tenderness on pressure is definitely localised to the tip of the spinous process of the fifth lumbar vertebra and the space below it. Pain is also felt on hyperextending the spine. There may be some spasm of the erector spinæ muscles, but usually the patient can bend forwards fairly freely, the movement taking place in the lumbar spine above the lumbosacral junction. These signs are quite sufficient for a diagnosis.

Now this condition looks as though it ought to be amenable to manipulation, but in our experience it is not, and the reason, I think, is that the lumbar spine is so movable that it is impossible to localise manipulation accurately to the lumbosacral junction. But it occurred to us that, if we could not stretch the ligaments, we could divide them. We therefore excised the spine of the fifth lumbar vertebra, thereby ensuring that everything attached to it was divided, and in every case in which we have done this the pain has been relieved and has not returned since. This is a minor operation, and I give it to you for what it is worth.

ACUTE AND CHRONIC LUMBAR BACK STRAIN

Acute back strain is another very common condition which presents quite definite clinical features. It is essentially a localised rupture of some of the deeper fibres of the erector spinæ muscle on one side, produced by muscular action. In proof of this is the fact that occasionally, though rarely, one of the transverse processes of a lumbar vertebra is pulled off by the violence of the muscular contraction. Without warning, the patient experiences a sharp pain like a stab in the back, either during some special effort, such as lifting a heavy weight, or while stooping in an awkward position. The sharp pain is succeeded by a dull ache in the back, which is most noticeable when the patient is sitting with the muscles relaxed. Later, the lumbar spine is found to be rigidly fixed by spasm, and every attempt at movement is pulled up by a sharp stab of pain in the back. On examination, the whole of the lower part of the back is found to be hyperæsthetic, and there is a localised point of tenderness over the erector spinæ on one side.

If seen when the condition has become chronic, there is a history of sudden onset, there is a point of localised tenderness over one erector spinæ, the muscle on one or both sides is strongly in spasm, and when the patient tries to bend forward he either does not bend at all or he inclines towards the painful side. Frequently there is a considerable degree of added neurosis, and I do not know of any trivial injury which causes such a profound and disproportionate sense of disability. The radiographic appearances are normal except in the rare instances in which there is a fracture of a transverse process.

The treatment of acute and chronic back strain should be prompt and decisive. It consists in immediate mobilisation of the spine by forcible manipulation under an anæsthetic, followed by massage and exercises. This usually cures the condition outright, unless there is an impending claim for compensation or a long-standing neurosis. The manipulation is practically the same in all cases—namely, forcible flexion, rotation in both directions, and finally hypertension.

SPINAL ARTHRITIS, WITH OR WITHOUT SCIATICA

A patient with spinal arthritis may or may not complain of his back. Many patients with this condition are quite unaware that there is anything wrong hands, and move it about in all directions, and particularly try to flatten out the sole. You will find that the movements are more or less restricted, and that in the traumatic cases there is usually stiffness and some pain on inversion as well as on eversion of the foot. If the foot is rigid from arthritis, leave it alone, or at least be cautious in your prognosis. Otherwise, manipulate without hesitation.

The manipulation consists in forcible movement of the foot in all directions, but particularly in the direction of abduction and eversion, and I must add that it is a man's job. Make no mistake about this; the manipulation is forcible and even violent. The manipulation of an adult foot often requires all the strength that a strong man can put into it, and I defy you to damage an adult foot with your hands alone. Next morning, put a good masseur on, and tell him to mobilise the foot and give exercises. The shoes, provided that they are well made and of a good shape, may be of the ordinary conventional type. A well-known bone-setter is said to have made two-thirds of his fortune by simply moving feet that other people would not move. It was not a stunt or deception practised on a credulous public, but perfectly sound surgery—empirical, it is true, but effective.

Twists and Sprains of the Knee

Now many, perhaps most, orthopædic surgeons would put the knee first among the joints which most often require manipulation. Personally I should put it third. But at any rate chronic sprains of the knee are very common, and the bone-setter might well have made approximately the other third of his fortune by empirically moving knee-joints that other people would not move. I use the word "empirically" deliberately, because I have evidence that this manipulation, too, was based upon an erroneous idea of the pathology of the condition—yet it served its purpose.

Twists and sprains of the knee-joint are very common. The usual mechanism is that, while the foot and leg are fixed upon the ground and the knee is slightly bent, the femur is forcibly rotated inwards by the whole momentum of the moving body swinging inwards. This movement of rotation actually takes place between the upper surface of the head of the tibia and the under surfaces of the semilunar cartilages. When the head of the tibia has reached the limit of its normal movement in this direction a state of tension arises and, if the force continues, something has to give way. On the inner side the tibia tries to drag the internal semilunar cartilage forwards. But the posterior end of this cartilage is firmly held down by the condyle of the femur and also by its attachment to the internal lateral ligament, so that a great longitudinal strain is thrown on the curved cartilage. A common result of this accident is that the cartilage is torn from its peripheral attachment to the capsule and springs like a bow-string towards the centre of the joint. This is the familiar bucket-handle detachment of the cartilage which is so often found at operations for displaced semilunar cartilage.

The symptoms of torn and displaced semilunar cartilage have been known to surgeons for very many years, and they are described in all text-books of surgery. It is universally recognised that, when a joint is "locked" by the cartilage getting caught between the bones, it must be freed at once by manipulation, for, if it is left, it will do irreparable damage to the joint. It is also known now that the only thing that manipulation can do in such a case is to displace the cartilage further towards the centre of the joint, where it may lie in the intercondylar notch, and with luck may not give trouble for a long time. It is known that a detached cartilage cannot be made to retrace its steps, as has been claimed by some people. And, lastly, it is known that fibrocartilage does not heal, so that even if it could be restored to its original position it would not become re-united. Personally I believe that a displaced cartilage should always be removed, because it nearly always gives rise to further trouble sooner or later, and it is significant that a very large proportion of the cases that are treated by manipulation in the first place come eventually to have their cartilages removed by operation.

But what surgeons failed for so long to grasp was that exactly the same accident which, if it went far enough, would tear the cartilage, might in fact stop short of actual detachment and produce instead a sprain of the peripheral attachment of the cartilage. A sprain is a rupture or tear in a minute or microscopical sense. A few fibres of the ligament are separated or torn; there is a little hæmorrhage around them, followed by exudation of fluid and infiltration by connective tissue cells—in fact, the usual simple inflammatory reaction to an injury, which ends either in complete resolution or in the formation of new fibrous tissue or adhesions at the site of the injury.

In the knee-joint this condition gives rise to a characteristic train of symptoms. There is usually a history of an initial twist of the knee, followed by pain on the inner side and perhaps some synovitis, but never any locking of the joint. The patient complains that the knee is weak, that it tends to give way, and that he then gets twinges of pain on the inner side, and perhaps some swelling. On examination, the knee looks normal; there is often a tender spot on the inner side over the joint cleft; movements appear to be normal, though there may be some pain on outward rotation of the leg; there is also some wasting of the quadriceps.

Now surgeons would not operate upon these cases, because there was no typical locking of the joint suggesting displacement of the semilunar cartilage, and, being unfamiliar with this minor degree of the same injury, they did nothing, except order some ineffective massage. So that the patients went in large numbers to bone-setters, who promptly cured them by manipulation, because these cases respond readily to manipulation of the joint. The bone-setter diagnosed them as cases of "slipped cartilage" and professed to put the cartilage back. Actually they were cases of chronic knee strain with adhesions about the peripheral attachment of the cartilage. But, as they were easily cured by manipulation, the bone-setter got the reputation of being able to cure cartilage cases without operation while the surgeon could only cure them by operation. The manipulation, of course, consists merely in forcibly putting the joint through its full range of movement in all directions, not forgetting rotation of the head of the tibia. The results, as I have said, are entirely satisfactory, the great majority of cases being promptly relieved of their pain. Here again we can improve upon empirical treatment by employing a proper anæsthetic and by ensuring efficient after-treatment.

Pain in the Back

In my experience, after the foot, the spine and the pelvic joints are the parts which most often require manipulation, and the conditions which call for it are among the commonest in general practice. In recent years an enormous volume of literature negative. He manipulated osteo-arthritis, he said, often with great benefit.

Dr. N. D. DAMRY related an experience of fracture of the olecranon in India. The doctor had frightened the patient, but the bone-setter had set it, supported it for a few days, and then manipulated the limb, with excellent result. Bone-setters had, he said, led the way in the doctrine of early movement.—Mr. BANKART said that in his experience *the last thing a bone-setter in this country* would do was to set a bone; if he suspected a fracture he passed the case on at once.

The CHAIRMAN related personal experiences of success following early manipulation. A spot of tenderness often remained just over the back of the joint in wrist sprains. A Colles's fracture often showed persistent pain over the styloid process of the ulna. In the middle of the calf there was often pain after ankle injuries. If these secondary lesions were not attended to early the result would be spoiled. All general practitioners practised manipulation; expression of the placenta was a skilled manipulation. Manipulation for uterine displacement had been recommended a few years ago by a Swedish authority.

REVIEWS AND NOTICES OF BOOKS

Reflex Activity of the Spinal Cord

By R. S. CREED, D. DENNY-BROWN, J. C. ECCLES, E. G. T. LIDDELL, and C. S. SHERRINGTON. Oxford: Clarendon Press. 1932. Pp. 183. 10*s*.

THE distinguished physiologists who have collaborated in the production of this book have sought to lay before the reader a concise account of what they style the "elementary features" of reflex mechanism, as it can be studied in the reflexes of the mammalian preparation at levels below the corpora quadrigemina. They are, indeed, desirous of restricting the term "reflex" to such phenomena as characterise post-quadrigeminal animals, and in consequence would not allow the term for any automatic activities at higher levels; ex hypothesi there would be no such thing as a cortical reflex. Whether such a distinction should be rigorously maintained is perhaps open to discussion. But be that as it may, the chief object of study in the book is the individual motor-unit, of which much more is known now than was known a short time ago. The individual anterior-horn cell is the "motoneurone"; its axone connects with perhaps as many as 160 separate muscle-fibres, the whole constituting a "motor unit." Interesting evidence is adduced which goes some way towards settling the question of whether neurones are structurally linked or not, the view here taken being that there is contact (by means of the neuronic arborisations known as "boutons terminaux" which are applied against the cytoplasm of the adjacent cell), but not anatomical continuity. There is thus a "surface of separation," to whose varying properties and conditions many of the qualitative differences as between reflex-arc conduction and nerve-trunk conduction are due.

The degree of activity of a given motoneurone depends on the algebraic sum of the opposed influences of excitation and inhibition which converge on it at any given moment; it is the "collision-field" of the two, which are both commonly at work. Such ways of phrasing the facts of experimentation undoubtedly suggest a "conflict" between opposing forces, yet elsewhere the process is described as one of "collaboration." On still another page we read that one influence acts "against" the other, as "more or less a counterpart and counterpoise." There is here surely that "coöperation of antagonism" of which Hughlings Jackson used to speak—an expression that can hardly be bettered. Considerably less is known of the locus of inhibition than of that of excitation; according to work here summarised, it lies "closely circumjacent" to the motoneurone itself.

The application of the manifold researches of the writers of the book to medicine and neurology in particular may appear somewhat remote, but physiology has already aided immensely in the understanding of clinical problems; and the clinician may hopefully peruse such a volume of up-to-date physiology as this with an eye to the interpretation of the symptoms that he encounters.

Anatomie élémentaire des centres nerveux et du sympathique

Second edition. By P. GILIS, Professor of Anatomy at the Faculty of Medicine of Montpellier. Revised by J. EUZIÈRE, Professor of Nervous and Mental Diseases, Montpellier. Paris: Masson et Cie. 1932. Pp. 234. Fr.24.

WE reviewed this book on its first appearance some five years ago. The new edition, of practically the same size, contains but few modifications. Its major portion is concerned with a minute description of the sympathetic nervous system, the form and functions of which are dealt with from the sensory, motor, and secretory side respectively. Though an elementary text-book, it nevertheless gives a fairly extensive account of its subject matter. the usefulness of which is increased by a series of simple schematic drawings —original, clear, and well supplied with explanatory legends.

Some Factors in the Localisation of Disease in the Body

By HAROLD BURROWS, C.B.E., F.R.C.S., Assistant at the Research Institute of the Cancer Hospital; Consultant-Surgeon of the War Memorial Hospital, Gosport. London: Baillière, Tindall and Cox. 1932. Pp. 299. 15*s*.

THE predilection of certain micro-organisms for particular regions of the body has long been recognised as one of the most interesting problems of the process of infection. In this monograph Mr. Harold Burrows puts forward the thesis that the localisation of many blood-borne diseases is due (1) to an abnormal permeability of the walls of small blood-vessels, (2) to the presence of forces which will transport the noxious agents through the endothelial cytoplasm, (3) to the retention of noxious agents in the tissues under the influence of inflammation. In the first part of his book the influence of the inflammatory process upon the permeability of vascular endothelium is discussed, also the permeation of the capillary endothelium by normal proteins, and the localisation in the tissues of foreign proteins, dyes, natural pigments, syphilis, bacteria, viruses, and cancer. The second part of the book deals with the factors concerned in localisation: the cause of the increased capillary permeation, the transport of matter from the blood stream to the tissues, and the retention of with their spines. They complain of sciatica. The great majority of cases of sciatica are suffering from spinal arthritis, and the pain is due to irritation of the roots of the sciatic nerve in the intervertebral foramina. On examination you will find that the movements of the lumbar spine are restricted and that the pain and tenderness are referred to the sciatic notch and down the trunk of the sciatic nerve. We do not pretend that spinal arthritis is more amenable to treatment than chronic arthritis elsewhere, but we do find that, if we can restore mobility to the lumbar spine, the pain may be relieved, and we have found that manipulation under an anæsthetic followed by physiotherapy may be expected to give relief, almost amounting to a cure, in about 50 per cent. of cases.

MEDICAL SOCIETIES

PADDINGTON MEDICAL SOCIETY

AT a meeting of this society, held at the Great Western Hotel on Oct. 11th, the chair was taken by the President, Dr. G. DE SWIETOCHOWSKI. Mr. A. S. BLUNDELL BANKART read a paper on Manipulative Surgery in General Practice, which is printed on p. 840.

The CHAIRMAN said that Mr. Bankart had thrown a good deal of light on the triumphs of the profession's successful rivals, the bone-setters.

Dr. H. C. WOODYATT asked what should be done for the foot in early convalescence if supports were to be deprecated.—Mr. BANKART replied that the discomfort of the support often discouraged rather than encouraged the use of the foot. Muscular action after illness should first be restored by massage. The only support he ever used was a wedge on the inner side of the heel.

Dr. W. G. BENDLE said he had often been puzzled by the success of bone-setters. Apparently the general practitioner had been too timid to perform manipulations which the bone-setter undertook unhampered by any knowledge of anatomy or pathology. He would like to know how long after injury manipulation should take place.—Mr. BANKART replied that he never rested a sprained joint unless it was too painful to touch. As soon as it could be touched he put a masseuse on to mobilise it. The best pressure for immediate application was a couple of small sponges; this generally brought the swelling down.

Mr. R. Y. PATON pointed out that surgery was the Greek word for manipulation, and had only secondarily become associated with "cutting" instead of "use of the hands." Bone-setters obtained their success because they did something at once, before the patient left the room. It did not matter if trouble recurred; the psychological effect of giving some immediate relief, announced by an audible click, was very great. He knew a man who had to wear supports in his bedroom slippers but could complete the annual Stock Exchange walk without trouble in ordinary shoes. This confirmed Mr. Bankart's theory of flat-foot. The foot, to be healthy, must be supple. He quoted the case of a girl who had twisted her knee and had it put right at once by a bone-setter; later she had put out the other knee, and a doctor had put her to bed and told her she had "water on the knee." After several weeks she had gone to hospital and been cured by the manipulation which she might have had at once. There were many movements not taught in anatomy. Full flexion and extension did not indicate a normal knee; there must also be rotation of the tibia on the femur. Internal rotation of the humerus was a movement of great importance to the patient. In some ankle strains the tibia rode forward a little on the astragalus; if it were pushed firmly it went back with a dramatic crack and the patient was greatly benefited.

After a Colles's fracture there might be much limitation of the smaller wrist movements, causing severe disability. Manipulation would restore them. Early function was of the greatest importance. Mr. Paton said that he was even making patients with Pott's fractures walk three days after operation. Fear was the chief factor in preventing early movement.

Dr. J. COHEN wondered whether the lithotomy position used in gynæcological operations had anything to do with low back pain following them, and whether bands of strapping over the sacro-iliac joint were of value. He quoted a case of persistent pain after fracture of a metatarsal; the patient had tried Scholl supports, but his pain had ceased as soon as his compensation was paid.—Mr. BANKART replied that he had no doubt that the lithotomy position was responsible for sacro-iliac strain. He could not conceive how strapping could have any effect on so deeply situated a joint with tremendous forces acting on it from above.

Dr. ALEX. BALDIE said that general practitioners lacked the clear-cut precision of thought of the specialist. It would have been very useful if the principles they had heard that night had been applied to the thousands of flat feet seen in the war. But if a third of these cases had been cured would not the others have shifted their neurotic symptoms to some other region? It was difficult to determine whether a case of backache was suitable for manipulation, for psychological treatment, or for occupational therapy. Man was a vertical animal for 16 hours out of the 24. Dr. Baldie asked to what extent obscure pains in the back were explicable by these habits of posture, and what was the diagnosis and treatment of this type.—Mr. BANKART said that postural backache was very common, especially in round-shouldered women with prominent abdomens. They had no spot of tenderness in the back. They were treated by remedial exercises or—if very fat—by abdominal supports. Many of them had a definite neurosis superadded, and an indefinite hyperæsthesia over the back. Their neurosis would not, however, be cured without manipulation to relieve its organic basis. Manipulative surgeons had to do a great deal of psychotherapy.

Dr. S. CROWN asked for more details of the patients with rupture of the erector spinæ.—Mr. BANKART replied that he had long hesitated to manipulate acute back strains, but he had seen dramatic cures, and had had very great success himself. The acute pain was largely due to muscular spasm, and the explanation of the relief was that manipulation paralysed this. No trivial injury caused such a profound disability and psychological effect; ignorant and imaginative people feared paralysis. This accounted for the traumatic neurasthenia in back strains, and was another reason for immediate treatment.

Dr. J. GREEN asked if manipulation were practised in rheumatoid arthritis.—Mr. BANKART replied in the negative. He manipulated osteo-arthritis, he said, often with great benefit.

Dr. N. D. DAMRY related an experience of fracture of the olecranon in India. The doctor had frightened the patient, but the bone-setter had set it, supported it for a few days, and then manipulated the limb, with excellent result. Bone-setters had, he said, led the way in the doctrine of early movement.—Mr. BANKART said that in his experience the last thing a bone-setter in this country would do was to set a bone; if he suspected a fracture he passed the case on at once.

The CHAIRMAN related personal experiences of success following early manipulation. A spot of tenderness often remained just over the back of the joint in wrist sprains. A Colles's fracture often showed persistent pain over the styloid process of the ulna. In the middle of the calf there was often pain after ankle injuries. If these secondary lesions were not attended to early the result would be spoiled. All general practitioners practised manipulation; expression of the placenta was a skilled manipulation. Manipulation for uterine displacement had been recommended a few years ago by a Swedish authority.

REVIEWS AND NOTICES OF BOOKS

Reflex Activity of the Spinal Cord

By R. S. CREED, D. DENNY-BROWN, J. C. ECCLES, E. G. T. LIDDELL, and C. S. SHERRINGTON. Oxford: Clarendon Press. 1932. Pp. 183. 10*s*.

THE distinguished physiologists who have collaborated in the production of this book have sought to lay before the reader a concise account of what they style the "elementary features" of reflex mechanism, as it can be studied in the reflexes of the mammalian preparation at levels below the corpora quadrigemina. They are, indeed, desirous of restricting the term "reflex" to such phenomena as characterise post-quadrigeminal animals, and in consequence would not allow the term for any automatic activities at higher levels; ex hypothesi there would be no such thing as a cortical reflex. Whether such a distinction should be rigorously maintained is perhaps open to discussion. But be that as it may, the chief object of study in the book is the individual motor-unit, of which much more is known now than was known a short time ago. The individual anterior-horn cell is the "motoneurone"; its axone connects with perhaps as many as 160 separate muscle-fibres, the whole constituting a "motor unit." Interesting evidence is adduced which goes some way towards settling the question of whether neurones are structurally linked or not, the view here taken being that there is contact (by means of the neuronic arborisations known as "boutons terminaux" which are applied against the cytoplasm of the adjacent cell), but *not anatomical continuity*. There is thus a "surface of separation," to whose varying properties and conditions many of the qualitative differences as between reflex-arc conduction and nerve-trunk conduction are due.

The degree of activity of a given motoneurone depends on the algebraic sum of the opposed influences of excitation and inhibition which converge on it at any given moment; it is the "collision-field" of the two, which are both commonly at work. Such ways of phrasing the facts of experimentation undoubtedly suggest a "conflict" between opposing forces, yet elsewhere the process is described as one of "collaboration." On still another page we read that one influence acts "*against*" the other, as "more or less a counterpart and counterpoise." There is here surely that "coöperation of antagonism" of which Hughlings Jackson used to speak—an expression that can hardly be bettered. Considerably less is known of the locus of inhibition than of that of excitation; according to work here summarised, it lies "closely circumjacent" to the motoneurone itself.

The application of the manifold researches of the writers of the book to medicine and neurology in particular may appear somewhat remote, but physiology has already aided immensely in the understanding of clinical problems; and the clinician may hopefully peruse such a volume of up-to-date physiology as this with an eye to the interpretation of the symptoms that he encounters.

BELLE VUE SPA AND HOTEL

TREFRIW, NORTH WALES

The combination of medical treatment and comfortable residence amid beautiful scenery offers great attraction to visitors as well as patients.

Thirty bedrooms, magnificent lounges, billiard room, tennis court, eight and a half miles of salmon and trout fishing, and golf courses within easy reach. The new bath and treatment rooms within the Belle Vue Spa's grounds, recently opened by an eminent surgeon, are equipped with the most up-to-date apparatus for electrical treatment.

The Belle Vue Spa sulphur-iron water (ferrous sulphate), described by medical men as the purest and most highly concentrated in the world, is collected from an ancient Roman mine according to medical advice, so as to prevent any air coming in contact with the iron water.

Sufferers from Rheumatoid Arthritis or Osteo-Arthritis in hips or knees, who have been bed-ridden for months or years and want to walk again without pain, can avail themselves of the Hoefftcke Ambulatory Extension Treatment.

Special facilities are provided for those requiring this treatment in the nursing wing under medical supervision.

This treatment has been favourably commented upon by many eminent medical men in the Medical Journals.

See *The Medical Press and Circular*, April 27th, 1932, pp. 348-351: Ambulatory Treatment of Fractures and Diseased Joints by the Hoefftcke Extension Splint.

For reprints and further particulars apply The Secretary, Belle Vue Spa, Trefriw, N. Wales, or Mr. C. A. Hoefftcke, 7, Harley Street, London, W.1.

colloids or other substances by inflamed tissue. The third part consists of a general discussion, and includes a section devoted to the consideration of the process of localisation on therapeutic measures.

Dr. Burrows has read widely. His book contains a wealth of information which will be of value to workers in this subject, and a bibliography of over 400 references is appended. Certain of his conclusions, however, seem to have little application to disease as it occurs in the human being. The numerous examples which he details of the metastatic localisation of various infections are of interest, as illustrations of a process which has long been recognised, but they do not explain the incidence of the primary disease; and in our view the author stretches his argument beyond reasonable limits when he applies his theory to the cancer process. It may be, as he says, that a primary malignant growth is due to the localisation of a circulating cancer virus in an area of inflamed or damaged tissue, but this is merely a hypothesis. Again, it is hardly correct to say that several malignant tumours in animals are initiated by viruses; nor will most pathologists agree that malignant metastases are due to the arrest of malignant emboli by the macrophage cells of the reticulo-endothelial sinusoids. One of the most pleasant features of the book is the series of coloured plates illustrating the localisation of pigments in the lesions produced in animals. These are beautifully reproduced, and indicate the valuable possibilities of intravital staining.

Clinical Atlas of Blood Diseases

Second edition. By A. PINEY, M.D., M.R.C.P., Director of Pathological Department, Cancer Hospital, London; and STANLEY WYARD, M.D., M.R.C.P., Physician to the Hospital. London: J. and A. Churchill. 1932. Pp. 105. 12*s*. 6*d*.

THE new edition of this atlas is in every way a worthy successor to its predecessor. The colour plates are among the best of their kind ever published and reflect the greatest credit on the artist, Mr. J. R. Ford, and on the printers. The letterpress accompanying the plates is apt and concise; the microcytic anæmia associated with absent or deficient hydrochloric acid in the gastric juice which has been described in this country by L. J. Witts and is probably the commonest of all types of anæmia in the British Isles escapes specific mention, but most of the common conditions are well described, while every possible hæmatological rarity receives attention.

An Introduction to Sexual Hygiene

By A. BUSCHKE, M.D., and F. JACOBSOHN, M.D. Translated by EDEN and CEDAR PAUL. London: George Routledge and Sons, Ltd. 1932. Pp. 193. 7*s*. 6*d*.

THIS book is a good example of a literature that is becoming profuse; it is, however, a translation from the German and there may be more need for it in the country of its origin than there would seem to be here. The structure and function of the reproductive organs of both sexes are clearly set out, some elementary considerations in respect of reproduction will be useful to lay readers, and the essays upon the problems of puberty and the sexual impulse are well devoid of fine writing and quite sane in their teaching. Facts that are disagreeable, some of which were till recently not accepted as facts, are faced, and the reasons for the conclusions upon debatable points are given. The advantages of birth control are taken for granted and some elementary information is supplied concerning certain techniques. Monogamy is regarded as the ideal form of marriage both for men and for women, and all forms of "modified marriage" are condemned. But a quasi approval of "companionate" unions, as a substitute for the early marriage that is so difficult in modern conditions, must be dependent upon the successful practice of birth control.

New Babes for Old

By WINIFRED DE KOK, M.R.C.S., L.R.C.P. London: Victor Gollancz. 1932. Pp. 191. 5*s*.

THIS book, which is intended for parents, contains an account of the development of infants and small children, and advice on their management and upbringing. It is written from the psycho-analytic point of view, and is illustrated throughout by notes of the progress and achievements of the author's children. Much stress is laid on the importance of weaning, in the happy management of which the seeds of all future conduct are held to lie. Much of the advice in this book will probably be found to work well with many children, but there is little recognition of the diverse ways in which different children respond to the same mode of upbringing. In some cases the author's optimism may lead to disappointment on the part of parents who adopt her recommendations, some of which are rather difficult to apply to existing social conditions.

A Manual of Pharmacology

Fourth edition. By TORALD SOLLMANN, M.D., Professor of Pharmacology and Materia Medica in the School of Medicine of Western Reserve University, Cleveland. London: W. B. Saunders Co., Ltd. 1932. Pp. 1237. 37*s*. 6*d*.

THIS important work has been revised and reprinted on ten occasions since it was first published in 1917. Prof. Sollmann's chief object has been to furnish medical students and practitioners with an outline of the current conception of the actions of drugs, especially from the point of view of their practical importance in medicine, and in this he has succeeded admirably. The book is, however, much more than a mere outline. By relegating to small print parts which the author does not regard as having a direct bearing on medical practice, he has been able to present a mass of information on all aspects of pharmacology, and has, in fact, made his book the best work of reference on the subject in the English language. He has added also an extensive bibliography which should be of great help to the practitioner and investigator who may desire to form an independent judgment or to obtain additional information. In the new edition many of the sections have been rewritten, the most important being those on the barbiturates, sexual hormones, arsphenamine compound, temperature regulation, vitamins, and the iodine compounds employed in roentgenography.

The book can be cordially recommended to everyone who desires an accurate and up-to-date work of reference on pharmacology.

THE LANCET

LONDON: SATURDAY, OCTOBER 15, 1932

PROFESSIONAL SECRECY

At the St. Pancras inquest, reported in another column, a medical practitioner was found to have taken the unusual step of cutting off and destroying the upper parts of the pages of his case-book sooner than permit the police the possible investigation of his patients' secrets. The privilege, it must be remembered, is the privilege of the patient not of the doctor. The moral obligation of professional secrecy is well established. There is undoubtedly a legal obligation as well. Some years ago, when the Court of Appeal was examining the banker's duty not to disclose his customer's account, Lord Justice Scrutton, in declaring that secrecy was an implied term of the contract between banker and customer, suggested that the same term would be implied between doctor and patient. In other words, a doctor is liable to an action for damages if he wrongfully discloses his patient's confidences. Lord Riddell, in his little volume on "Medico-Legal Problems," remarked that the absence of copious direct legal decision on this point must be due to the consistently discreet and uncommunicative behaviour of the medical profession. It is well known that no cause of action can arise in respect of anything said by a witness in a court of law. Nor is there any doubt that the law insists on a doctor answering in court all such questions as the interests of justice may require to be put to him. Refusal to answer exposes him to the serious and summary penalties inflicted for contempt of court. It is not quite clear to what further lengths legal insistence will go. The doctor must give information to the judge in court: need he give it to the policeman outside? Is he obliged to set the criminal law in motion?

A simple and possibly not uncommon example of the dilemma occurs where a doctor is called in to attend a woman upon whom an illegal operation has, as it seems to him, been performed. What is he to do? In 1896 Mr. Justice Hawkins told a grand jury that he very much doubted whether, in such a case, the doctor could be justified in reporting the facts to the Public Prosecutor: "such action would be a monstrous cruelty." The Royal College of Physicians of London thereupon took the opinion of the late Sir Edward Clarke and Mr. Horace Avory (now the distinguished High Court judge) who confirmed Hawkins's opinion. A medical man, they advised, was not liable to be indicted for the practically obsolete offence of misprision of felony, merely because he does not inform the police in a case where he suspects criminal abortion. Misprision of felony, it may be explained, is the offence of concealing (or procuring the concealment of) a felony when one knows that some other person has committed a felony. In December, 1914, Mr. Justice Avory reopened the matter by enlarging, as it seemed, the medical practitioner's responsibility. A woman who died as the result of an illegal operation had been attended by three doctors. She was understood to have mentioned to one or more of these the name of the abortionist. But, because none of the doctors passed on the information to the police, no dying statement was taken, and there was insufficient evidence for convicting the person accused in the case. The learned judge, while conceding the general duty of medical secrecy, told the grand jury that this was an instance where the desire to preserve the confidential relation should have been *subordinated to the good* citizen's duty to assist in the investigation of serious crime. Expressing the wish to clear up all misunderstanding or misrepresentation as to the opinion he had given 20 years earlier, Mr. Justice Avory declared that it might be the moral duty of the medical man, even in cases where the patient is *not dying or not unlikely to recover*, to communicate with the authorities when he sees good reason *to believe that a criminal offence* has been committed.

> "However that may be, I cannot doubt that in such *a case as the present, where the woman is, in* the opinion of the medical man, likely to die, and therefore her evidence likely to be lost, it is his duty; some one of these gentlemen ought to have done it in this case."

It is noteworthy that the words "moral duty" rather than "legal duty" were used. One might also perhaps classify judicial colloquy with a grand jury as something less conclusive and authoritative than a decision of the Court of Criminal Appeal. Not unnaturally, the observations uttered at Birmingham took the medical profession by surprise. Amongst other bodies which examined the legal position more closely in consequence, the Royal College of Physicians of London obtained from the censors' board a report containing medical and legal opinions. This report was adopted by the College in July, 1915, and was circulated to the Public Prosecutor, the Royal College of Surgeons, the General Medical Council, and the medical press. The Public Prosecutor taking exception to some of the legal advice, the terms of the report were varied. Finally, resolutions of the College were published in February, 1916, after obtaining the opinion of counsel (the late Sir Richard Muir). Counsel's opinion was mainly devoted to the admissibility in evidence of dying statements, and the method of recording such statements. The resolutions first sum up what the College believes to be the proper professional practice. That is to say, they reaffirm the solemn duty to respect a patient's confidence. They state that the doctor who is convinced that a third person has performed an illegal operation should urge his patient, especially if she is *likely to die, to make a* statement which may be available against the abortionist, provided always that the effort of persuading the patient does not prejudice her prospect of recovery. They state that the College

PRACTICAL FOOD INSPECTION

In Two Volumes. Vol. I.—**MEAT INSPECTION**

By C. R. A. MARTIN, M.R.S.I., A.M.I.S.E., Senior Sanitary Inspector, Whitstable, etc.

Publisher's Note.—This work is published with the object of making available to inspectors, students, and others, a book embracing important post-war technical and administrative developments in food inspection, written by a practical inspector.

Sykes' MANUAL OF GENERAL MEDICAL PRACTICE. Second Edition. Crown 8vo. **7s. 6d.** net; postage 5d.
". . . delightfully written . . . contains much sound practical advice."
—QUEEN'S MEDICAL MAGAZINE.

Lewis Jones' MEDICAL ELECTRICITY: A Practical Handbook for Students and Practitioners. Eighth Edition. 14 Plates and 197 other Illustrations. Demy 8vo. **22s. 6d.** net: postage 9d.
". . . has established its claim beyond any doubt."
—BRITISH MEDICAL JOURNAL.

JUST PUBLISHED. Crown 8vo. **6s.** net; postage 4d.

NATIONAL HEALTH INSURANCE

By G. F. McCLEARY, B.A. (Camb.), M.D., D.P.H., formerly Principal Medical Officer, National Health Insurance Commission (England), and Deputy Senior Medical Officer, Ministry of Health, etc.

READY NEXT WEEK. Crown 8vo. **4s.** net; postage 3d.

THE INJECTION TREATMENT OF VARICOSE VEINS, HAEMORRHOIDS AND OTHER CONDITIONS

By RODNEY H. MAINGOT, F.R.C.S., Surgeon, Royal Waterloo Hospital, London; late House Surgeon and Chief Assistant to a Surgical Unit, St. Bartholomew's Hospital, &c.

Osler's ÆQUANIMITAS: With other Addresses to Medical Students, NURSES, AND PRACTITIONERS OF MEDICINE. Second Edition. Ninth Impression. Post 8vo. **7s. 6d.** net; postage 6d.
"Written with all the breadth of view and the beauty of style which make Professor Osler's writings so characteristic and so valuable."—THE LANCET.

Jelliffe and White's DISEASES OF THE NERVOUS SYSTEM. A Text-book of Neurology and Psychiatry. Fifth Edition. With 475 Engravings and 13 Plates. Royal 8vo. **47s. 6d.** net.
". . . the best account in English . . ."—BRITISH MEDICAL JOURNAL.

SIXTH EDITION. Plates from Original Drawings (6 in Colours) and other Illustrations in Text. Demy 8vo. **30s.** net.; postage 9d.

ON DISEASES OF THE LUNGS AND PLEURÆ

Including TUBERCULOSIS AND MEDIASTINAL GROWTHS

By **Sir RICHARD DOUGLAS POWELL**, Bt., K.C.V.O., M.D. Lond., F.R.C.P., late Physician-in-Ordinary to H.M. the King; Consulting Physician to the Middlesex and Brompton Hospitals; and **Sir PERCIVAL H.-S. HARTLEY**, C.V.O., M.D. Camb., F.R.C.P., Physician, St. Bart.'s Hospital; Senior Physician, Brompton Consumption Hospital, etc.

". . . . can be confidently recommended as a safe guide to the practitioner in search of authoritative medical opinion."—BRITISH MEDICAL JOURNAL.

Rea's AFFECTIONS OF THE EYE IN GENERAL PRACTICE. With 7 Coloured Plates and 35 other Illustrations. Demy 8vo. **10s. 6d.** net; postage 6d.
". . . the practitioner will find it supplies his needs in good measure."
—THE LANCET.

Master's ALCOHOL HABIT AND ITS TREATMENT. Crown 8vo. **6s.** net.
"This volume deals clearly with the subject of alcoholism."—THE LANCET.

Gregory's INFANT WELFARE. *For the Student and Practitioner.* Crown 8vo. **4s. 6d.** net; postage 4d.
". . . extremely practical and clearly expressed."—THE LANCET.

Moxon's PATIENT'S MANUAL OF DIABETES. Crown 8vo. **6s.** net. postage 4d.
". . . an excellent manual . . . should prove invaluable."
—GLASGOW MEDICAL JOURNAL.

LONDON MEDICAL EXHIBITION: Stands 32, 40, 41

October 17th—21st. Noon till 6.30 p.m. Daily

London: H. K. LEWIS & CO. LTD., 136 Gower Street, W.C.1
Telegrams: "PUBLICAVIT, EUSROAD, LONDON." Telephone: MUSEUM 7756-7-8.

this greater mortality from tuberculosis of the lungs or tracheo-bronchial glands in Scottish children in contrast with those in other parts of the world. "It may be," he writes, "that, on account of the relatively isolated position of this country as compared with others, the opportunities for infection in the past . . . have prevented the development of the same racial resistance in Scottish people as in those of other countries."

A noteworthy feature of Dr. BLACKLOCK's investigation is the light which he throws on the pathway of infection to the lung and lymphatic glands. A characteristic primary lung lesion was described originally by PARROT (1876), KUSS (1898), and later by GHON, CANTI, and others, as occurring in the human subject and corresponding to the primary site of infection. This lesion was found by Dr. BLACKLOCK in 148 out of 173 cases in which the first site of infection was considered to be thoracic. Of the cases with primary foci, 133 had one each, and in 15 they were multiple, giving a total of 170 primary lung lesions. All of them showed evidence of caseation; in some further changes—cavitation, fibrosis, or calcification—had occurred. These primary lesions were found more often in the right lung than in the left, the right upper lobe being most frequently involved, and then in order, the right lower, the left upper, the left lower, and lastly the right middle lobe. The anterior aspect of the upper and middle lobes was most frequently affected, the apex of the upper lobes, however, was seldom the site of a lesion. In both lower lobes the primary foci were most frequently found in the lower two-thirds posteriorly. The tracheo-bronchial glands in direct anatomical relation to these foci were always diseased, and the important fact emerged that the occurrence of the primary lesion in any particular lobe was the important factor in determining the distribution of the glandular lesions. Macroscopic and microscopic examinations indicated that the lesions in the primary focus and related lymph glands were either of the same age or else that in the glands was more recent. No retrograde spread from the tuberculous tracheo-bronchial glands back into the lung substance was observed. In some of the cases there was spread of the tuberculous adenitis to the glands in the neck, or to the lymph glands in the upper part of the abdomen, but this was always secondary to that at the root of the lungs, and the intensity of the adenitis diminished the further away it was traced from the glands in direct anatomical relation to the focus in the substance of the lung. Concerning the significance of these primary foci, the pathological and histological evidence cited renders it unlikely that they are of hæmatogenous or lymphogenous origin. Dr. BLACKLOCK concludes that they are ærogenic, and adds that unknown factors must determine the predominant localisation to a single primary focus. From cases in which the primary lung lesion was found, only human types of bacilli were obtained, either from the lesion itself or from the glands in direct anatomical relation. If the focus had been of hæmatogenous origin, bovine bacilli should frequently have been found, in view of the fact that bovine strains were isolated from 81·8 per cent. of the primary abdominal lesions in children from the same series of autopsies as those with primary thoracic lesions.

Tuberculosis in the child is an obscure and controversial subject. Dr. BLACKLOCK's report contains a great wealth of material, skilfully handled. It should do good service in letting light into many dark places, and his pathological and bacteriological evidence should be reflected in more reasoned clinical treatment and the medical administration of juvenile tuberculosis.

FIFTY MILLION BOTTLES OF MEDICINE

THE Ministry of Health tells us that last year over 50 million prescriptions were dispensed for 15 million insured persons, and that of these prescriptions over 60 per cent. were for mixtures. Yet, as Dr. E. KAYE LE FLEMING so pointedly emphasised in his inaugural address to St. George's students, abstracted in our last issue (p. 801), the art of prescribing is not a strong point in the general practitioner's training; much more instruction, he thinks, might well be given in the medical curriculum on this subject. Dr. LE FLEMING went on to deprecate the use of the phrase "the bottle of medicine fetish"; this gibe, he said, comes more often than not from a critic with no personal knowledge of prescribing, and who is as ignorant of the real therapeutic value of drugs as of the psychology of human nature; the best answer to criticism of this kind would be found in the issue of the new Pharmacopœia. He went on to deal with the old fallacy, which dies so hard, that a panel patient is debarred from having the same range and quality of drugs as the private patient, and that an insurance doctor who prescribes the best for his patients will be admonished and surcharged. The panel patient, he said with emphasis, may have anything necessary for his proper treatment; but it is unfortunately true, he added, that the medical student has little opportunity for acquiring a knowledge of the values of remedies before he engages in practice, and it is as easy to be extravagant in prescribing as it is in eating or drinking. Nevertheless, out of 14,840 doctors issuing prescriptions last year under the National Health Insurance Acts, only four were surcharged for excessive prescribing.

In his presidential address to the West London Medico-Chirurgical Society last week, the sub-title of which we have taken for this article, Dr. JULIUS BURNFORD made a comprehensive survey of therapeutics, past and present. Consider, he said, how man must have suffered since he began to take notice of his ills and to trust to others for relief. Consider how through the ages he has been physicked; what an experiment in tolerance! And he went on to cite all the various sources from which medicine in the ages had drawn its stock of drugs and remedies. Treatment had followed treatment in endless stream and variety, though, as if to remind us that there is nothing new under the sun, old treatments were apt to reappear in is advised that, if the patient refuses to make the statement, the doctor is not legally obliged to pursue the matter further. They observe that, if the patient dies, the doctor should refuse to give a certificate of the cause of death, and should communicate with the coroner. This last observation will now, of course, be read in conjunction with the 1926 legislation and the consolidated Regulations of 1927 as to death registration; under Part IX. of the latter the registrar reports to the coroner any death which appears, from the contents of the medical certificate, to have been due to abortion. The resolutions of 1916 went on to emphasise the legal position by declaring that the doctor is under no legal obligation either to urge the patient to make a statement, or, if she refuses to do so, to take any further action. It is significant that this statement of the legal position was submitted to the Director of Public Prosecutions before publication, and is understood to have had his complete approval.

If the resolutions of 1916 are taken to represent organised medical opinion, independent medical writers have expressed their own hesitations. Although it is no part of a doctor's duty to act as an auxiliary policeman, is it any part of his duty to screen a professional abortionist? Lord RIDDELL, admirably summing up the problem in the volume already cited, remarks that the practice of abortion has greatly increased since the resolutions were passed. He asks whether, apart from legal obligation, the medical profession is justified in helping to conceal acts of this nature especially where the case is one of a series performed by the same abortionist. The answer seems to depend on the strength of public opinion, whereon ultimately the law itself and its enforcement are founded. Since Lord RIDDELL's book was published in 1929, judicial utterances have shown that the law itself is uncertain. What obligation can there be upon the doctor to aid in bringing an abortionist to justice if the judge holds that a charge of criminal abortion is an obsolete anachronism? If some of our judges think this and others think the opposite, the legal consequences of medical secrecy are a mere gamble.

◆

JUVENILE TUBERCULOSIS: A SCOTTISH INVESTIGATION

THE gaps in our knowledge of tuberculosis in childhood are gradually being filled up as diagnosis becomes more accurate. Clearer knowledge is leading to more precision in defining our terms. L. COBBETT has pointed out, for instance, how the old phrase tabes mesenterica, which used to figure so largely in practitioners' death certificates, has declined in frequency during recent years, doubtless in favour of a more accurate terminology. A monograph published this week[1] goes a long way toward closing the gaps still further. Dr. BLACKLOCK has made full use of his opportunities as pathologist to the Glasgow Royal Hospital for Sick Children in an exhaustive study of the tuberculous lesions, obvious or suspected, in a series of 1800 consecutive autopsies at the hospital during the years 1924–31. He has thus made it possible to collate the figures for Glasgow and the West of Scotland with those previously obtained for Edinburgh and the East, and afforded a basis for checking the figures already available from America, England, and Germany. Dr. BLACKLOCK's work helps, too, to define the differences between tuberculosis of childhood and tuberculosis of the adult. And last, but by no means least, the details of his post-mortem records provide material, extremely valuable to comparative pathologists, for comparison with the data set out[2] by Dr. H. H. SCOTT as a result of observations on the children of non-immunised Chinese at Hong-Kong and of higher apes in the London Zoo.

After determining the bacteriological type of the tubercle bacilli isolated from cases at autopsy—both those dead of tuberculosis and those dead of other causes—and from cases of surgical tuberculosis still alive, Dr. BLACKLOCK concludes that 37 per cent. of the bacilli are of the bovine strain, a finding which leads him to the conclusion that bovine tuberculosis is more prevalent in Scotland than in England or on the continent. Out of the total number of 1800 cases investigated post mortem, 283 showed tuberculous lesions, and in these 173 (61·1 per cent.) were considered to be due to a primary infection of the thoracic tissues. Wherever this primary lung lesion was found, only bacilli of the human type were obtained, whereas there was a high incidence of bovine strains in *primary abdominal lesions*. The high preponderance of bovine strains in abdominal lesions will excite no surprise, but the total absence of bovine strains from the thoracic lesions in the Glasgow autopsies is of considerable interest in view of the recent figures—chiefly in young adults—given[3] by W. T. MUNRO at Fife and Kinross Sanatorium in the East of Scotland. Of 28 cases of cervical adenitis, 10 yielded human and 18 bovine strains, a percentage of bovine origin lower than that found in most other investigations of Scottish children, but again higher than English and continental figures. A similar result was obtained with bone and joint tuberculosis, affording strong evidence that in Scottish children there is a special prevalence of bovine infection. In his large experience of autopsies upon adults in Glasgow, Dr. BLACKLOCK has rarely found evidence of healed infantile damage, and this fact leads him to the conclusion, contrary to the views expressed in other parts of the world, that it is exceptional for a dormant infection received in childhood to flare up later. But he also finds that pulmonary tuberculosis in young children in the West of Scotland is nearly always fatal—as indeed it is reputed to be elsewhere. Is it not possible, therefore, that there are but few survivors to break down in adult life? Dr. BLACKLOCK finds it difficult to explain hæmorrhagic tendency can be counteracted by transfusion or injection of normal blood. This has been the method of treatment of hæmorrhagic disease of the new-born for many years, and it is extremely rare to find a case that does not respond rapidly to one or more injections. Heffernan[3] has for the past four years given prophylactic injections of maternal blood routinely to every baby immediately after delivery, and reports a series of 800 cases. These include normal, low and high forceps, and breech deliveries, and 68 cases of Cæsarean section. Of the mothers 148 suffered from toxæmia; and there were 46 premature births. No case of hæmorrhagic disease occurred, and the mortality-rate during the first ten days was 2·5 per cent., or 1 per cent. excluding those born before the seventh month. Four infants developed symptoms indicating intracranial hæmorrhage and subsequently recovered. In carrying out the treatment 20 c.cm. of blood was taken from the antecubital vein of the mother and injected into the loose areolar tissue of the infant's infrascapular regions, 10 c.cm. on either side. No suppuration or anaphylactic reactions were observed, and the blood was absorbed in 24 to 36 hours. While the number of cases treated is not large enough to prove the value of prophylactic injection as a routine, the low incidence of hæmorrhage of any severity in the series is striking. The procedure is apparently harmless, and might well be adopted at least in those cases where there are any factors predisposing to hæmorrhage, especially prematurity, maternal toxæmia, or prolonged or difficult delivery.

ELECTRO-COAGULATION OF THE TONSILS

THE destruction of the tonsils by diathermy is the subject of an important contribution by Mr. R. Graham Brown,[1] of Brisbane. In his view, more or less satisfactory results are being obtained by those experts in throat surgery who are endowed with the requisite dexterity and who have a knowledge of the diathermy current. But he deplores the fact that many practitioners throughout Australia have been persuaded to buy diathermy apparatus in the belief that the difficulties they had experienced in the surgical treatment of diseased tonsils would be eliminated, and that a few simple coagulations with a diathermy needle would be effective. Far from this being true, Mr. Graham Brown holds that it is even more difficult to treat tonsils by surgical diathermy than by dissection. He quotes the following among the incorrect statements which are made by interested parties: that the tonsils can be completely removed without inconvenience or loss of time to the patient in three, four, or five sittings; that the coagulation and its after-effects are painless; that, although portions of the tonsil may remain after treatment, these portions are sterile; that the remains (which apparently are tonsillar) are generally nothing more than granulation tissue; that coagulation by diathermy does not lead to "bottling up" of the crypts. Mr. Graham Brown relates in detail a series of seven cases, previously treated by diathermy coagulation, which exemplified certain types of focal infection, and subsequently had to be surgically enucleated. These cases demonstrated the inaccuracy of the statements quoted above; several afford striking instances of increased toxæmia resulting from the bottling-up of septic material beneath the diathermy scar. Mr. Graham Brown is satisfied that total removal can be performed almost painlessly, and with practically no subsequent discomfort, provided that little destruction is done at each sitting, and that a degree of patience is exercised which is seldom found in patients and still less in surgeons. But he is emphatic in his opinion that, especially in the small buried type of tonsil, no treatment short of complete removal should be advocated for fear of greatly increasing the septic absorption from these structures. He has performed a useful service in making it clear that the method is a difficult one, which requires special skill, and often a very prolonged course of treatment, and that it is far from being an easy short cut to the desired end of complete extirpation of the septic tonsil.

AMAUROTIC FAMILY IDIOCY

A REPRINT has reached us of a long article on the juvenile variety of amaurotic family idiocy published last year by Dr. Torsten Sjögren.[1] It constitutes a valuable addition to knowledge in respect of a rare nervous disease which seems to occur with greater frequency in Sweden than elsewhere. Dr. Sjögren describes as many as 39 personally observed cases—in all probability more than any other worker has ever seen; and with this rich material at his disposal he is able to supply a clinical analysis that has never been approached. We are given detailed tables relating to inheritance, time and mode of onset, and other clinical peculiarities; the material is handled also from the viewpoint of familial and geographical distribution, ætiology, and pathogenesis. Its pathology did not come within the scope of this research. As a result of his investigations Dr. Sjögren concludes that the disease is distinguished by a more or less regular clinical syndrome and evolution; attention is directed particularly to the changes in the fundi, the epileptic fits, and extrapyramidal symptoms, such as hypertonus and other defects of motility. From a Mendelian point of view the condition seems to have the characters of a recessive; in this respect its heredofamilial features differ from those of the infantile variety. Other questions of interest are discussed in the monograph, which contains a full bibliography and is well documented.

AN INDEX TO PROGRESS IN SEVERE INFECTIONS

THE value of the sedimentation rate of the red cells in enabling the course of pulmonary tuberculosis to be followed and the response to treatment to be gauged has long been recognised; recently Dr. W. W. Payne drew attention[2] to its use in determining the latency or activity of rheumatic infection in children; but in this country, at any rate, it has hitherto played little part in general clinical medicine. Dr. J. W. Cutler,[3] of the Henry Phipps Institute of the University of Pennsylvania, as the outcome of a long series of observations, concludes that this procedure is capable of affording much more help than has hitherto been recognised. The nature of the phenomenon remains a mystery, but Dr. Cutler regards it as proven that an increase in the rate is associated with any condition in which there is increased tissue breakdown, and that the rate affords a correct indication of the degree of this breakdown. The test could thus give no help in the diagnosis of any particular morbid condition, but is capable of affording an index to progress more new guises; nevertheless, with each revival there comes a more scientific rationalism. He dwelt on the inherent difficulty in judging of the effect of remedies; how tolerance on the one hand, and the tendency to recover without treatment on the other, combined to render difficult and uncertain the assessment of any line of therapy. Nor is the living organism comparable with the machine in the accuracy of its working; rational therapy has always to contend with the many variants of the living organism. Of the final efficacy of treatment he regarded the patient as the best judge; in so far as the doctor retained the trust of his patient, he must have attained to some success. The patient, it is true, had much faith in the bottle; but in the main, he thought, we had passed the borders of empiricism. The discovery of opium, for instance, was empirical, and, as we are still ignorant of its action, empirical it remains. The same was no longer true of cinchona bark, for the advances of protozoology and the discovery of the active parasite and its life-history had led to a determination of the exact lethal activity of quinine. But even now we did not know whether EHRLICH'S "606" acted directly on the spirochæte or indirectly through a tissue reaction. Sometimes enthusiasm for a new line of treatment may have led to a forgetfulness of the fact that the whole individual is disordered in a disease. In an otherwise fertile era of post-mortem study of disease advance was held back by focusing attention on end-results; living pathology had carried us a stage further in the recognition of early processes and the searching out of ætiological principles. But our modern therapeutics might at times be doing injustice by not incorporating the experience of the past. At this stage Dr. BURNFORD surveyed briefly the whole field of modern treatment, concluding with a salutary consideration of its failures. Our therapeutic armamentarium may now be great; how much of it will stand for all time? We are acting according to our lights, and hence rationally by that same view; but let us in all humility remember that the witch or the priest chanting incantations acted just as rationally in the light of their own day.

ANNOTATIONS

TAXATION OF COD-LIVER OIL

A LEADING newspaper last Sunday, in dismissing opposition to the Ottawa agreements, remarked that even the dissenting Liberals cannot be exactly stirred to the depths by the reflection that their cod-liver oil will cost them more. The medical profession is hardly likely to share this light-hearted view of the proposed duties. Year by year it is made clearer that the diet of the poorer classes—if not the richer—is not the "balanced diet" advised by the text-books. Report after report, on rickets, dental caries, maternal mortality, or infectious disease, emphasises the importance of plenty of fresh foods or (if these are too expensive) of cod-liver oil, during infancy, childhood, pregnancy, or convalescence. In cod-liver oil we have a cheap and plentiful source of vitamins A and D; its more general use might go a very long way towards supplying the dietary deficiencies by which industrialism and poverty damage the national health. The taxation of bread would cause little perturbation among dietitians, for under present circumstances even the poorest people would still obtain it through work or charity. It is otherwise with the protective foods—milk, butter, eggs, fruit, and vegetables—which are the first to be sacrificed in time of hardship. It is at such times that cod-liver oil is most required to counteract the evils of an excessively cereal diet; and if steps could be taken to increase, perhaps tenfold, the consumption of cod-liver oil by children and young persons, something definite would have been done to counteract the effects of the present depression. It is the fear of an opposite tendency that causes us anxiety. Arguments about the actual result of the proposed tariff are complex, and the suggestion is repeatedly made that even a 50 per cent. duty could easily be borne by the middlemen and distributors who at present absorb most of the proceeds of sale. Into this economic and commercial argument we do not propose to enter. But we say emphatically that any measures which did in fact reduce the sale of cod-liver oil in this country would be contrary to the public good.

PREVENTION OF HÆMORRHAGE IN THE NEW-BORN

THOUGH mortality in the first two years of life has been greatly reduced during the present century the proportion of infants dying before the tenth day is still very considerable. And this remains true of countries where sepsis and infantile tetanus can be held responsible for very few of the neonatal deaths. Analysis of the available pathological material in many series of autopsies on new-born babies has indicated intracranial hæmorrhage as a common cause of death. Thus B. Fisher[1] noted hæmorrhages visible to the naked eye in 65 per cent. of the brains of 500 infants, and a similar finding was reported in our columns by J. N. Cruickshank[2] in 200 examinations. When it is considered that for every fatal case of intracranial hæmorrhage there are probably many cases of minor hæmorrhage which may or may not cause permanent damage to the nervous system, the importance and frequency of the condition may be realised. R. J. Heffernan[3] has estimated its incidence as high as even 20 per cent. in all new-born babies. The cause of the hæmorrhage appears, as a rule, to be intrinsic rather than extrinsic. It is true that in a certain number there will be found gross damage to the intracranial tissues (such as a tear of the falx cerebri or the tentorium cerebelli), and that death has followed a difficult labour or faulty obstetrics; such fatalities can only be eliminated by improved obstetric technique. There remain, however, the great number of cases where delivery has been easy and the labour in every way normal. In these hæmorrhage appears to be due to the innate tendency of the new-born infant to bleed. It is by no means clear which elements of the blood or vascular system are responsible, since it is found that either bleeding-time or coagulation-time, or both, have a tendency to be prolonged in the new-born infant, whilst even in true hæmorrhagic disease of the new-born the findings are not constant. It is, however, certain that the most marked), the basal ganglia, optic thalamus, and dentate nucleus. Prof. de Lange's studies have been very exactly carried out and, in particular, so that no confusion should arise, attention has been directed to the appearances of the various areas of the brain in normal infants. In this way it is possible to assert that much of the existing work of the histology of the nervous system in pink disease is unsatisfactory, and the present findings are in accord with the careful studies of W. G. Wyllie and R. Stern and of D. Paterson and J. G. Greenfield in this country in which a small-celled infiltration, believed to be of glial origin, was reported. The patient, in this instance, was a boy nearly a year old, and death was sudden, associated with an alarming acceleration of the pulse. This increased frequency of the pulse, especially in fatal cases, is a feature of pink disease requiring further elucidation. Changes have been described in the vagus nerve and Dr. Gertrud Steinbach[2] describes a case in an older child where electrocardiographic records were made. The patient was a boy over six years old, who presented a fairly typical picture of pink disease with photophobia, nasal catarrh, apathy, lassitude, severe sweating, loss of weight, and the characteristic appearances of the hands and feet. The pulse-rate varied between 160 and 180 per minute, keeping just as rapid during sleep. An electrocardiogram made at this time showed undoubted evidence of myocardial damage. In all three leads the R S T complex was altered considerably. Indeed, the form of the S-wave is believed to be unique, while the T-wave was inverted in leads I. and II. Four months after the beginning of the illness there was definite improvement in the general condition, the pulse was less than 100, while the electrocardiographic changes showed only a slight return towards normality, and changes of a pathological nature still appeared to be present. Since the prognosis is usually good in pink disease, save for the cardiac complication, these studies are of interest and suggest further investigation, perhaps in other centres.

IS FATAL HEART DISEASE ON THE INCREASE?

IN his Statistical Review of England and Wales for 1926, the Registrar-General concluded that "alarmist pronouncements as to increase of mortality from heart disease by 'the stress and worry of modern life'" were not founded on fact, and could indeed be met by the observation that it is declining at all periods of life. The increase in the *crude* mortality (about 13 per cent. between 1911–20 and 1926) is due to two factors: (1) the ageing of the population—standardised rates and rates at ages show decreases; and (2) the "rapidly growing tendency to record cardiac degeneration in certifying deaths of old people formerly ascribed simply to such causes as 'old age,' bronchitis, &c." That the "appalling increase" in the mortality from heart disease observed in the United States is probably equally fictitious is shown in a recent paper issued by C. F. and N. W. Bolduan from the Department of Health of New York.[3] The registered increase in heart disease in New York City has been accompanied by a registered decrease in apoplexy, Bright's disease, and deaths charged to senility. In New York City the efforts of the registrar of records have, it is stated, reduced the deaths charged to senility from 35 per 100,000 of population in 1900 to less than two in 1930, and well over one-half of these deaths are now comprised under the comprehensive heading "cardio-arterio-renal disease." A consolidation of these registered forms of death (apoplexy, acute and chronic heart disease, arterial disease, nephritis, and senility) shows, in spite of the ageing of the population, a practically constant death-rate for cardio-arterio-renal disease over the period 1900 to 1930. Only at ages 65 years and over is there any signs of an increase, and even this increase is slight. At all other ages a distinct fall in mortality is noted. The registered mortality from "heart disease" alone is therefore fallacious; this is the conclusion of these authors, and it is a conclusion which seems well founded. The pathological changes and the ætiological factors in heart disease are not limited to the heart, but include also the arteries and kidneys. Fashions of certification, improving accuracy, and methods of classification of death may play a large part in influencing the recorded mortality in the elements of this group of causes. The great prevalence of cardio-arterio-renal disease presents a very important health problem, which certainly requires no exaggeration by fallacious figures.

CARAVANS

WHAT is locally described as the caravan menace is becoming quite serious along certain parts of the Sussex coast. Small caravan towns, with a population of holiday-makers and week-end dwellers, have sprung up here and there on the outskirts of popular resorts and in places are said to be destroying the amenities of the district. What is considered more important is the fact that these settlements have no sanitary arrangements and may become centres of infection. Faced with this situation, the rural authorities are seeking Parliamentary action, led by the Westhampnett rural council which has in its midst caravan settlements at Aldwick, Selsey, Middleton, Felpham, and the Witterings, all of which are by the sea. The authorities are invoking the assistance of the West Sussex County Council in promoting a Bill giving the same powers as were given to the Surrey County Council in its 1931 Act. Power is needed to regulate the uses of all land bordering on the sea-shore. Many farmers are profiting by letting their fields to caravaners, and although the fields are exempt from rates under the De-rating Act when they are used exclusively for the purpose of agriculture, the rating exemption can be forfeited by devoting the land to another purpose. It then becomes assessable, as in ordinary cases, on the basis of the value to a hypothetical yearly tenant. The local authorities, it appears, are bringing the question to an issue by assessing the farmers. Several of the large towns on the south coast already have powers to check the caravan menace.

EARLY DIAGNOSIS BETWEEN AMŒBIC AND BACILLARY DYSENTERY

Dr. John Anderson[1] writing of the differential diagnosis of dysenteries in the Eastern Mediterranean during the late war noted that early cases of amœbic could be distinguished from bacillary by the microscopical examination of the stools, even if amœbæ could not be seen. In amœbic dysentery, he found, red cells were nearly always present, and apt to be clumped; the eosinophils were much increased; the polymorphs were digested and reduced to pyknotic nuclei, owing to a proteolytic process at work;

accurate than any hitherto available. Dr. Cutler uses a type of sedimentation tube devised by himself, which holds 1 c.cm. of blood and is graduated into 50 divisions of 1 mm., each corresponding to 0·02 c.cm. of blood. Readings are taken over an hour at intervals of five minutes. Four distinct types of graph are recognised: an almost horizontal line, a diagonal line, a diagonal curve, and a curve approximating to the vertical; the first alone is normal; the remaining three indicate increasing degrees of intensity in the morbid condition. Dr. Cutler finds that the sedimentation rate is increased in all chronic and acute infections, in local suppuration, in acute intoxications, and in certain endocrine disorders, such as thyrotoxicosis. It is only slightly influenced by simple catarrhal inflammations, and not at all by functional or mental disorder, allergic conditions, simple neoplasms, or chronic valvular disease of the heart. While the test may have some value in establishing a differential diagnosis, particularly where a neurosis is suspected, its principal value lies in the aid which it affords in following progress. Dr. Cutler cites several examples of malignant disease and of pulmonary tuberculosis in which the sedimentation rate by indicating progress of the disorder appeared to belie the clinical course; in every case, the evidence of the test proved in the long run to be correct. The only physiological condition associated with increase of the rate is pregnancy, in which there is a steady increase from the second month on to parturition.

SPINAL ANALGESIA: THE CAUSES OF DANGER

MUCH controversy has raged round the question of how the fall in blood pressure and the respiratory depression which sometimes dangerously complicates endothecal injection of anæsthetics are brought about. Perhaps the most commonly accepted view has been that paralysis of many vasoconstrictor fibres led to splanchnic dilatation and "pooling" and that the drop in blood pressure was due to this and that respiratory depression followed secondarily. The matter has been experimentally investigated recently by researches carried out in the University of Wisconsin[1] to study the relationship between oxygenation of tissues and the maintenance of good cardiovascular function during spinal analgesia. The authors start with the thesis that three mechanisms may be involved in the respiratory paralysis which they regard as the usual cause of death on the table from spinal anæsthesia. These are: (1) Direct action on the respiratory centre by diffusion of the drug to the fourth ventricle in paralytic concentration. (2) Ascending block of the intercostal and phrenic nerves. These two may be arrested by proper dosage and technique. (3) Insufficient nutrient flow of blood through the central respiratory mechanism secondary to cardiovascular depression. This depression, they say, is attendant on every intradural block involving the upper part of the abdomen and thorax. As the integrity of the respiratory centre depends on an adequate volume of sufficiently oxygenated blood the depression is responsible for most cases of respiratory failure. Experiments on dogs do not substantiate the view that paralysis of the splanchnic nerves with subsequent pooling of blood in the abdominal region are the principal if not the only factor involved in the circulatory depression. Loss of skeletal muscle-tone, which accompanies any intradural block, removes an element essential for the maintenance of a stable capillary and venous bed. The authors hold that it matters little practically whether paralysis of splanchnic nerves, or of vasoconstrictors to the skin and to other vessels of the trunk and extremities, or loss of skeletal muscle-tone is the principal factor. The important fact is that a marked decrease in peripheral resistance to blood flow occurs in the region involved in the block. Grave cardiovascular changes occur only in blocks that involve the chest. Two important factors must be considered: additional paralysis of vasoconstrictor fibres and intercostal nerve paralysis. The integrity of the medullary centre and heart is dependent on adequate supply of oxygen. The additional anoxæmia accompanying partial or complete thoracic paralysis may be disastrous. The main contention of their thesis is that the oxygen needs of the body are not adequately met, owing to a reduced volume flow of blood and a decreased gaseous exchange in the lungs proportional to the lowered thoracic excursion. Experimentally the efficiency of respiration, thoracic excursion, and minute volume exchange decreased in blocks involving the thoracic region and the decrease is proportional to the height of the block. Compensation by increased diaphragmatic activity may occur in the low thoracic blocks. This reactivity of the diaphragm is hindered in the Trendelenburg position. Studies of the alveolar and blood oxygen and carbon dioxide both in man and dogs gave the authors further evidence of the decrease of pulmonary ventilation in blocks involving the thorax. They drew the practical conclusions that to combat cardiovascular collapse there should be judicious use of inhalation of oxygen throughout the surgical procedure, prophylactic administration of ephedrine, a moderate Trendelenburg position, and administration of fluid while blood-vessels and heart still maintain their physiological integrity. Artificial respiration with undiluted oxygen is to be practised when there is impending circulatory or respiratory failure and post-operative hyperventilation of the lungs with carbon dioxide periodically throughout the first 24 hours after operation.

STUDIES IN PINK DISEASE

THE story is told of a French physician, visiting a well-known children's hospital in London, who asked an English colleague, after a case of "erythrœdema polyneuritica" had been demonstrated, "qui est ce monsieur Pink?" It is not only in France that the name of pink disease is unfamiliar, but fortunately its characteristics are now more widely recognised, and detailed studies of the condition are being made at various centres. Prof. Cornelia de Lange,[1] of Amsterdam, for instance, has lately described an investigation of the central nervous system from a patient whose brain and spinal cord were sent her by Dr. J. C. Spence of Newcastle-on-Tyne. Briefly, the findings in this case were a slight increase of neuroglial tissue in certain parts of the brain, in areas this being collected together into small "glial nodes." There was nowhere any evidence of change in the neuronic elements and no sign of any inflammation except for a small localised area of meningitis over the left frontal area, only discovered on careful microscopical research. No changes were found in the spinal cord, and in the brain the principal areas showing this increase of glial tissue were the tubero-infundibular region (where the glial nodes were

POST-GRADUATE LECTURES

THE following abstracts are from post-graduate lectures delivered in connexion with the special short courses recently held at Charing Cross (Mr. Norman Lake), St. Mary's (Mr. Herbert Tilley), Middlesex (Mr. E. W. Riches), and King's (Dr. J. L. Livingstone).

THE SURGERY OF THE SYMPATHETIC NERVOUS SYSTEM

(MR. NORMAN LAKE)

MODERN interest in the sympathetic system may be said to date from the pioneer work of the English physiologists, Langley and Gaskell. The former included in his "autonomic system" two distinct entities working more or less in opposition—the sympathetic proper, consisting of the central sympathetic cords and ganglia, together with certain peripheral ganglia; and the parasympathetic, consisting of fibres associated with somatic nerves, those from the third cranial passing to the ciliary ganglion, visceral branches of the seventh, ninth, and tenth cranials, and the pelvic branches of the second, third, and fourth sacrals. Langley's conception in its main outlines still gives us the most acceptable working hypothesis upon which to base our studies. While surgical attack has been made upon the parasympathetic side of the system, the majority of operators concern themselves with the sympathetic proper.

Put briefly, the function of the sympathetic system is to prepare the organism for offence or defence, and to inhibit such functions as are not immediately concerned in this protection. Thus, the heart is accelerated and its output increased, the cutaneous vessels are contracted, so passing more blood to the muscles, sweat glands are stimulated, the hair is erected, and the pupil dilated. Peristalsis and secretion of internal viscera is inhibited, but the sphincters are contracted; there is chemical mobilisation of materials essential to a ready supply of energy, and increased function of certain endocrine glands such as the adrenals. Afferent fibres convey impulses from the viscera into the central nervous system, giving rise to that rather vague and diffuse sensation recognised as visceral pain.

The anatomy of this system is too complex to allow of a brief summary, but as a result of experimental and surgical study considerable advances have been made during the past ten years in our knowledge, not only of the anatomical details, but also of the functions of the fibres.

The first deliberate surgical attack upon the sympathetic system was apparently that of W. Alexander, of Liverpool, who excised the superior cervical ganglion for epilepsy; ten years later, in 1889, Jonnesco excised the whole cervical cord for the same condition, and a little later Jaboulay and Jonnesco attacked the cervical sympathetic in cases of exophthalmic goitre. In 1915 Leriche introduced his operation of peri-arterial sympathectomy, and, although this operation has since been shown to be founded upon a mistaken anatomical basis and as a result has been largely discredited, it served to arouse an interest in the possibilities of sympathetic surgery which has not waned since. In 1916 Jonnesco operated upon the cervical sympathetic for the relief of pain in angina pectoris with apparent success. Eight years later Hunter and Royle, in Australia, suggested the operation of lumbar ramisection in the treatment of spastic paraplegia. This operation, also established upon an unsound anatomical and physiological basis, was soon discarded for paraplegia, but every surgeon who performed it was impressed by the very marked vascular change which occurred in the affected limbs, and to which any improvement was almost entirely due. As a result, the possibility of relieving vasospastic conditions by this means was rapidly appreciated and put into practice.

At the present day the following diseases are treated by attack upon the sympathetic system, chiefly the division of the vasoconstrictor fibres, or better, the complete removal of that portion of the chain and its ganglia from which they arise: Raynaud's disease, thrombo-angiitis obliterans (Buerger), scleroderma, Hirschsprung's disease, angina and other visceral painful crises, retinitis pigmentosa, the vasospastic type of rheumatoid arthritis (Adson), and, still more tentatively, causalgia, intermittent claudication, and some painful amputation stumps. Many of the vascular symptoms associated with cervical rib are of sympathetic origin and the removal of the rib should therefore be included in this list. The splanchnic block, so extensively used in abdominal surgery, is also an instance of temporary interference with the sympathetic system, while attempts are being made to achieve a more permanent block by the paravertebral injection of alcohol in appropriate locations, with a view to supplanting operative division, with its attendant risks, in cases, particularly, of angina.

My personal experience is limited to the use of the operations in cases of Raynaud's disease of both upper and lower extremities; for pre-senile gangrene; for spastic paraplegia; for Hirschsprung's disease; for causalgia, and, very tentatively, in an effort to modify the motility and secretions of the stomach. The results have, in the majority of cases, been sufficiently good to give reason for enthusiasm on the part not only of the surgeon but also of the patient, and careful tests of function in the various structures, before and afterwards, have amply demonstrated the change which has occurred. In general, it can be said that good results are to be anticipated in cases of Raynaud's disease, thrombo-angiitis obliterans, and Hirschsprung's disease, and that in each of these the degree of improvement can be estimated beforehand by blocking the sympathetic cord with local anæsthetic or, better, by the administration of a spinal anæsthetic. In the case of the other conditions mentioned the operations must be regarded, frankly, as being very much in the experimental stage, although they have given results of an encouraging nature.

In the case of angina the propriety of any operation to relieve the pain has been called into question, and is still the subject of considerable controversy. Obviously, if the pain be protective or warning in character operative division of the sensory fibres would be a mistake, although division of motor vasoconstricting fibres could not be subjected to the same criticism. Nevertheless, I believe it to be open to great doubt whether it is right to regard pain of visceral sympathetic origin as being a protective mechanism in the sense that most somatic pains are so regarded. However, the question bristles with difficulties, and it is impossible to enter into a discussion of it now; nor would it be of any real value, and there were few macrophages. In the bacillary stools, on the other hand, there were few red cells, eosinophils were rare, polymorphs were swollen and killed by toxic necrosis, and macrophages (intestinal epithelial cells) were a striking feature. These observations are now confirmed, 11 years later, by Prof. A. Alexieff,[2] of Batoum, who observes that it is not always easy to find *Entamœba histolytica* in the stools of early amœbic dysentery, but that if pseudopyknotic nuclei (Anderson's pyknotic) are present the diagnosis is certain; here he quotes Anderson in support. The diagnosis is clinched, he says, by the finding of Charcot-Leyden crystals and eosinophils, but they do not develop quite so early in the disease. He details clinical cases which support his view that the deeper the seat of infection, the more of these digested polymorphs there will be—many if the infection is submucous, few if it is superficial, for then the ferments of the amœbæ are diluted by the intestinal juice. The amœba, he believes, gives off a proteolytic ferment which dissolves the cytoplasm of the polymorphs, but acts less strongly on the nuclei. In a very severe case, he found 85 per cent. of these pseudopyknotic nuclei, and notes that the similarity between his figure and Anderson's 83 proves the severity of the cases Anderson was concerned with. Alexieff gives drawings of the gradual release of the nucleus of the polymorph, and concludes that the presence of pseudopyknotic nuclei in the stools is the first recognisable sign of the presence of *E. histolytica.*

RECOGNITION OF FŒTAL DEATHS

IN reviewing the radiological signs of intra-uterine death Dr. Otto Brakemann[3] says that as many as 12 of these have been described by various writers. His own experience is based on an examination of 35 cases, and states that the best radiograms are obtained when the uterus is at rest, and, therefore, before the onset of labour and when the head is above the pelvic brim. A pathognomonic sign (first described by Spalding and Homer) is the overlapping of the flat skull bones, the frontal bones sliding under the parietals. Brakemann considers that an equally valuable and much earlier sign which he has encountered as soon as 14 hours after intra-uterine death is a step-like depression of the frontal and occipital bones below the level of the parietals without any overlapping. At the same time, the occipito-frontal diameter of the head is increased. A third sign is the triangular shape of the skull. Towards the occipital end the head is elongated into the form of an empty sac. The lamboidal sutures become widened, and in consequence the small fontanelle gapes widely. These changes are caused by the post-mortem softening of the cranial contents and cessation of the blood and lymph circulation, leading to decreased intracranial pressure, while the intra-uterine pressure of the liquor amnii on the fœtal head is maintained, at the same time as the membranes between the bones are softened. In twin pregnancy death of one fœtus can rarely be diagnosed with certainty apart from radiographic pictures which show the characteristic changes. Brakemann believes that in twin pregnancy the living fœtus can be endangered by poisonous substances emanating from its dead partner. This occurs especially if the partition between the two is torn; but it can, he thinks, happen also when the partition is intact, the injurious materials passing by osmosis from one amniotic sac to the other. He relates a case in which the death of one twin was diagnosed by X rays. Some time afterwards the mother went into labour; the living child presented by the breech and was born without difficulty, but only survived one hour. Post-mortem examination failed to reveal any cause of death, and he concludes that it had been poisoned by the passage of noxious material from the dead twin. On this account he advocates the termination of pregnancy for the sake of the living twin in cases where death of one fœtus has been demonstrated radiographically.

Sir George Newman will deliver the Harveian Oration of the Royal College of Physicians of London at 4 P.M. on Tuesday next.

Dr. Carl Prausnitz, professor of hygiene in the University of Breslau, is giving the Heath Clark lectures at the London School of Hygiene and Tropical Medicine, next week. His subject is the Teaching of Preventive Medicine in Europe, and Sir George Newman will take the chair at the opening address on Monday the 17th, at 5 P.M. The lectures will continue daily at the same hour until the 21st, and no ticket is required for admission.

THE Semon lecture for 1932 will be given by Prof. Otto Kahler of the University of Freiburg, at the house of the Royal Society of Medicine, 1, Wimpole-street, W.1, at 5 P.M., on Thursday, Nov. 3rd. Mr. E. Musgrave Woodman will take the chair, and the subject of the lecture will be the Tonsil Problem.

THE British Congress of Obstetrics and Gynæcology will meet in Birmingham from April 19th to 21st, 1933, the main subject of discussion being the Mechanism of Uterine Action and its Disorders. The hon. secretary is Mr. W. E. Barnie-Adshead, 89, Cornwall-street, Birmingham.

THE annual dinner of the Royal Society of Medicine will be held at the May Fair Hotel on Thursday, Nov. 17th, at 7.30 for 8 P.M. The guests will include Sir Thomas Barlow, Sir Hilton Young, and Sir William Rothenstein.

ROYAL MEDICAL BENEVOLENT FUND.—At the September meeting the committee voted 69 grants, amounting to £1421, as compared with 31 grants, amounting to £577, at the September meeting in 1931. The following are particulars of a few cases helped:—

Widow, aged 65, of M.R.C.S. Since the death of her husband in 1906 she had enjoyed an income of £250 per annum paid from money left in trust. The trustee who had entire control of the trust has proved to be fraudulent and is now in jail. The widow's income has therefore suddenly and unexpectedly stopped as all securities have disappeared, and she is left penniless. Fund voted special gift of £20 and £26 payable in four instalments over one year.

Widow, aged 36, of M.R.C.S. Husband died at the age of 38, leaving widow with a yearly income of £33 and three children, ages 6, 4, and 2, to maintain and educate. The husband had a distinguished war service, received the D.S.O. for outstanding courage, and paid for his medical education from what he received from the war. He was working as a medical officer on a salary of £500 per annum which was eaten up in the simple necessities of life. By his early death from phthisis his widow and three young children are left without means of support. Fund voted a special gift of £20 and £26 payable in four instalments over a period of one year.

M.R.C.S., aged 71. Applicant has [illegible] He is now totally incapacitated fr[illegible] the neck and arthritis. His wife has [illegible] last 40 years. Applicant's income was £96 per annum. He is obliged to employ help in dressing, walking, and general needs. Fund voted £10 payable in four instalments over a period of one year.

Cheques should be made payable to the honorary treasurer of the Fund, 11, Chandos-street, Cavendish-square, London, W.1.

[3] Münch. med. Woch., 1932, lxxix., 1079.

small and blocked nasopharynx hinders their profuse secretion from passing downwards into the lower pharyngeal regions.

I will henceforward confine my remarks almost entirely to the antrum as a frequent source of purulent nasal discharge, but it will be readily appreciated that as the other sinuses are not only in close anatomical relationship, but are also organically associated by a continuous ciliated mucous membrane. This has a practical bearing, in that neglect in the diagnosis and treatment of one infected sinus may sooner or later lead to involvement of its neighbours—e.g., it is a common experience to find apparently recent types of inflammation in the anterior ethmoidal cells and frontal sinuses associated with a similar but more chronic condition in the antrum.

Infection is, of course, due to bacteria, and it is generally of a mixed type in which staphylococci, streptococci, and pneumococci are in evidence, although either of these may predominate the others. In acute infections—e.g., influenza and the acute specific fevers—pure cultures of the invading organism have been obtained. If the pus has a foul odour, its dental origin should be suspected.

Acute inflammation of the maxillary antrum.—This is a frequent complication of an acute coryza, influenza, and the acute specific fevers. In such cases the infection passes from the nasal cavity into the antrum—and often involves the other sinuses which, by reason of their dependent drainage, tend to recover more quickly than the maxillary air cell in which the "ostium" is comparatively high up on its inner wall and is also covered by the swollen tissues of the middle turbinal. Another and not infrequent source of acute antral inflammation is the bursting into its floor of infective material from the apices of the roots of the second bicuspid and the first and second molar teeth.

The main symptom is acute pain in the cheek, often of a neuralgic type, and the patient will experience considerable tenderness if pressure be applied beneath the cheek on the anterior wall of the canine fossa. Sometimes the chief complaint is severe pain above the inner half of the corresponding orbit, but it does not necessarily imply that it is due to inflammation in the frontal sinus—in other words, it is a "referred pain," of antral origin. Transillumination of the antrum by means of a 4-volt lamp held in the closed mouth, and with the head covered by a dark cloth, will sometimes demonstrate that the suspected sinus does not show so clear an infra-orbital crescent of light as that on the normal side. (The small torch-light used for examining a throat will often suffice for this test.) You will now examine the nasal cavities, and first of all the healthy side, which will be fairly patent and covered with pale pink mucous membrane, while the suspected side would be obstructed by swollen congested mucosa and possibly a quantity of mucoid or mucopurulent discharge. If you spray on to, or apply to, the mucous membrane a 10 per cent. solution of cocaine and examine again in about five minutes, it may be possible to see the anterior regions of the middle meatus, wherein you may be able to detect a definite yellowish discharge. This will clinch the diagnosis in so far as antral infection is concerned. In cases of dental origin the symptoms are rather different, in that the patient will tell you that he had a bad toothache which suddenly passed off, and he then noticed a foul smell, and discharge from the nose from the same side.

In cases of intranasal origin treatment will be both general and local. The former will largely depend on the nature of the infection. If it is of influenzal origin, rest in bed will be necessary, and the pyrexia must be treated by ordinary remedies. Neuralgia and pain in the cheek will be greatly minimised by aspirin grs. 7, pyramidon grs. 3, salicylate of quinine grs. 2, codeia gr. ½, given in a cachet every four to six hours. Hot fomentations to the cheek are often very acceptable. It is most important to promote free discharge from the antrum. This can be much encouraged by applying beneath the anterior half of the middle turbinal a thin pledget of wool or gauze soaked in equal parts of 10 per cent. cocaine and adrenaline. If you can do this every three or four hours for at least a day, you may promote a drainage of septic material from the antrum and thus initiate a cure. What is still better is scarification of the anterior half of the engorged tissues of the middle turbinal and the adjacent meatus—it is often surprising how this local depletion adds to the patient's comfort, in addition to promoting freer discharge for the antral secretions.

If the antral trouble arises from a diseased tooth, this must be removed, the upper regions of the alveolus enlarged, and daily irrigation practised until the discharge ceases. The prognosis in such cases is good, and restitution should be complete in ten days to a fortnight.

Chronic antral suppuration.—Here let me repeat my warning that a patient's statement that he is suffering from "chronic nasal catarrh" often turns out to mean that the cause of the troublesome discharge is infection of one or more of the nasal sinuses. It will probably be a correct diagnosis if the symptoms are unilateral, because there is no such disease per se as a unilateral chronic nasal catarrh.

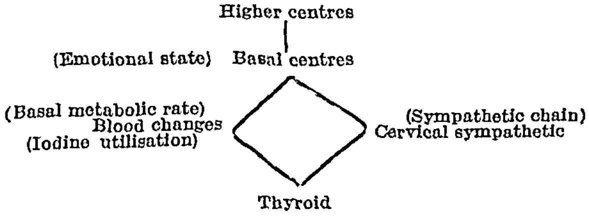
As a rule there are three predominant local symptoms: (1) A chronic yellowish discharge from the corresponding nasal cavity. It is often offensive, and particularly so if the antral infection be of dental origin. (2) Some degree of nasal obstruction. (3) Headache, generally supra-orbital, worse in the earlier hours of the day and wearing off about midday. The general symptoms may be merely those indicative of a mild toxæmia—e.g., never feeling fit, unrefreshing sleep, or lack of concentration on work. In other instances, digestive disorders are complained of, a fact not to be wondered at when one remembers that an ordinary adult antrum will hold at least an ounce of pus, and a considerable quantity of this would be unconsciously swallowed.

"Chronic laryngitis," "bronchial catarrh," and asthma are not uncommon symptoms resulting from the passage of septic organisms into the lower air passages. In all patients who suffer from recurrent pulmonary symptoms, mild or severe, it would be wise practice to make sure that the focus of infection does not lie in the nasal sinuses. The same would be equally true when looking for the cause of fibrositis, neuritis, and arthritis. It is interesting to notice the excellent work which during the past few years has been carried out by Drs. Graves and Pickworth and Watson-Williams, bearing on the relationship between mental disease and septic infections of the nasal sinuses. In many instances these septic psychoses—as Dr. William Hunter has termed them—have been cured by removing the source of infection.

Diagnosis will demand a close inspection of the middle meatus of the nose, and if pus is to be seen there you will have first to decide if the antrum is infected. Transillumination, as already described, may show an absence of the infra-orbital crescent of for what the practitioner wants to know is what class of disease to refer for surgical treatment, with reasonable hope of amelioration or cure, and I hope that the answer to that has already been made sufficiently clear. Of the future it is difficult to say much. Our knowledge of the distribution and working of the sympathetic system is still very imperfect, and intelligent anticipation of possibilities is correspondingly limited. Prophecy, without substantiation, is always easy, but alien to the scientific method, and imagination is apt to run riot when uncontrolled by a sufficient knowledge of the facts; yet, so great is the temptation, that, with full appreciation of these criticisms and warnings, I shall surrender myself for a brief moment.

The very clear association of certain organic changes with emotional states has long been recognised—exophthalmic goitre, mucous colitis, and atonic visceroptosis, to take three at random, have each their characteristic emotional state. The relationship between the two aspects of the disease have, in the past, been thought to be of a subtle nature, not capable of easy analysis. It may well be, however, that in the sympathetic nervous system we have a "mechanism" by which this relationship is effected, thus placing it upon an anatomical and physiological basis. The emotions are very closely related to the activities of the sympathetic system, may indeed be but the appreciation of the reflex responses of this system to appropriate incoming stimuli. Upon this thesis, therefore, the alteration in sympathetic response which produces the organic change must of necessity be associated with an emotional change, since it constitutes the physical basis of that emotion.

Such a viewpoint must change considerably our ideas as to the nature of these diseases, and may possibly lead to drastic alterations in the method of attack. It is beyond doubt that such a disease as exophthalmic goitre may be treated with success of varying degrees by the surgeon, the radiologist, the physician, and the psychologist, each with his individual ideas of the pathogenesis of the condition. Such an anomaly, however, becomes easier of explanation if we think of this disease as a circle, in which the basal centres of the brain, the cervical sympathetic system, the thyroid gland, and the blood form four segments. Thus, if there be any change in the response of the basal ganglia (the experimentally located centre of sympathetic activity), this will produce corresponding changes in the activities of the whole sympathetic system, including the glands which it controls—e.g., thyroid and adrenals—and this alteration will constitute the physical basis of an emotional change (the "emotional centre" also has been located in the basal ganglia). This circle is cut into by the surgeon when he performs a thyroidectomy, by the radiologist when he reduces the activity of the gland, by the physician when he attempts to neutralise the toxic thyroid secretion in the blood, by the psychologist when, by analysis, he affects the response of the basal centres; and finally Jaboulay and Jonnesco have both achieved some measure of success in the treatment of this disease by excision of part or the whole of the cervical sympathetic chain. This conception is perhaps best made clear by a graphic representation (see above) A similar relationship can be shown to exist in other physical diseases associated with emotional states. Is it too much to hope therefore that the sympathetic system will prove to be the link between physical and psychical, and that the surgeon's knife may thus have its repercussions upon the emotional state of the patients?



While this aspect of the subject interests surgeon and physician alike, the former may see in the sympathetic nervous system a means of altering the function of structures quite remote in its conception to the present-day surgery of direct mechanical attack Here we must add a further observation of great importance. It is possible that prolonged disturbance of function may produce definite organic changes, a thesis that is ably supported by the recent work of Telford and Stopford upon thrombo-angiitis obliterans where the well-known organic obliterative changes in the vessel wall are preceded by a primary functional spasticity dependant upon a sympathetic lesion.

If such "surgery of function" should eventually replace the clumsier methods of to-day the faltering attacks which we are now making upon the sympathetic system will not have been in vain.

PURULENT NASAL DISCHARGES

(MR. HERBERT TILLEY)

It is perhaps natural that those of us who confine our attention to diseases of the ear, throat, and nose are often surprised by the little attention which is given by members of our profession to such an obvious and common symptom as a purulent nasal discharge. I say "surprised" because we all know how many diseases are of septic origin, and can often be cured by the removal of the focus of infection.

For example, a patient complains of "chronic nasal catarrh"; if questioned he may say that it is chiefly on one side, and that sometimes he has noticed a streak of yellow in the discharge when he blows his nose. What happens? His throat is inspected and practically no examination made of the nasal cavities, but he is given a prescription for an alkaline nasal wash to be followed by a nebulised spray of an oily medium containing menthol or chloretone. So things drift on until some definite local or distal symptoms declare themselves, which call for a careful search for some hidden source of septic infection.

A purulent nasal discharge may be met with at all ages from the cradle to the grave. In the new-born child we are familiar with the condition in congenital syphilis or from some septic contamination during parturition. In children up to the tenth year, or even later, a foreign body should always be suspected if the discharge is unilateral, and particularly so if a little blood is sometimes mixed with the pus. Should examination exclude this possibility, the antral sinus will generally prove to be infected. In this connexion I would like to emphasise the fact that within recent years it has amply been proved that children are by no means exempt from infection of their nasal sinuses. A bilateral mucopurulent nasal discharge in those of tender years is one of the commonest symptoms of adenoids, for when these are mildly infected the (*b*) The cutting type, which employs a wire loop activated by a cutting current, and by means of which the tissue can be excised with little bleeding and without preliminary coagulation.

On general surgical principles the latter would appear to be the better type, for it leaves a minimal surface zone of dehydration on which healing readily occurs; whilst in the former type sufficient coagulation to prevent bleeding is likely to be followed by rather deeper necrosis which will provide a medium for the spread of infection. This objection is to some extent overcome in the Bumpus instrument, where the circular cutting punch follows accurately in the cylinder of tissue previously desiccated by multiple needle electrodes, and it is probable that resection can be more rapidly carried out by this type of instrument. I have preferred, however, to use the cutting type which, although it entails the removal of smaller and more numerous pieces, appears to leave a cleaner post-operative field.

The most modern of the cutting instruments is the McCarthy electrotome; it is essentially a modified posterior urethroscope. Vision is provided through a telescope giving a fore-oblique view, the field being kept clear by continuous irrigation. Hæmorrhage is slight, but any spurting vessel can be controlled by light coagulation with a ball type of electrode. The actual cutting mechanism consists of a wire loop movable to and fro by a rack-and-pinion movement and insulated from the rest of the instrument but connected with the source of diathermy. After the urethra and bladder neck have been examined, the loop is advanced to just beyond the obstruction, the ocular end is elevated, the current turned on, and the loop slowly withdrawn, during which movement it cuts through the projecting prostatic tissue. The piece, about an inch in length by a quarter of an inch in depth and width, usually adheres to the loop and is removed after each cut. When a sufficient amount of tissue has been removed, it should be possible to see from the verumontanum to the trigone of the bladder. Removal of the obstructing part only is aimed at, and the amount will vary therefore in different cases. A catheter is then inserted, the endoscopic tube withdrawn over it, and the catheter tied in; it is an advantage to use a self-retaining catheter of the Malecot or Pousson type.

Choice of operation.—In a purely glandular type of enlargement with considerable intravesical projection in an otherwise fit man an excellent result can be anticipated from suprapubic prostatectomy, and this is still the operation to be advised in such cases. In general, the larger the prostate the more suitable it is for suprapubic removal.

The selection of cases for per-urethral treatment depends on the local condition of the prostate and the general condition of the patient; as regards the local factor the operation gives most promise in the following types:—

1. Early glandular hypertrophy with only moderate intravesical projection.
2. Fibrous prostates.—After suprapubic prostatectomy convalescence is usually smoother in the glandular than in the fibrous cases; the same obtains after endoscopic resection, but to judge from the small amount of material at present available the latter is the more satisfactory operation.
3. Carcinoma.—Endoscopic resection can prevent or delay the necessity of suprapubic drainage with its attendant discomforts; it may have to be repeated.
4. Calculous prostatitis, if the infection can be controlled, should be more suitable for endoscopic resection than for suprapubic prostatectomy.

The general considerations are those which make suprapubic prostatectomy a hazardous procedure, such as cardiovascular or respiratory disease, extreme age or obesity; per-urethral methods are less hazardous, and the operation can be carried out under low spinal anæsthesia. In cases with impaired renal function, much cystitis, or acute retention, the preliminary establishment of suprapubic catheter drainage is a factor of safety; any pre-operative infection must be rigorously treated. There must be some mortality from this as from any operation in this type of case, but it is considerably less than after prostatectomy.

After operation the catheter is left in for two to four days with frequent irrigation; on its removal the patient can pass water, but some residual urine remains which must be removed as required until post-operative œdema subsides. Micturition is sometimes painful at first, and there may be transient slight loss of control, due probably to stretching of the external sphincter by the instrument. The patient leaves hospital after seven to ten days, and his sexual function is not altered by the operation.

As disadvantages may be cited the possibility of recurrence of obstruction, or of missing an early carcinoma, although the pieces are suitable for biopsy. The chief dangers appear to be sepsis and urethral shock. The operation demands much patience, but time spent at it is more than regained in the after-treatment.

ASTHMA AND DESENSITISATION

(DR. J. L. LIVINGSTONE)

DESENSITISATION of asthmatics, as of other allergic patients, may be either specific or non-specific. Specific desensitisation is carried out with the actual substance to which the patient is sensitive; non-specific desensitisation with some substance which is antigenic. Allergy is thought to be due to the presence in the blood stream of too many unsaturated antibodies; a non-specific substance used as a desensitising agent reduces the allergic state by causing saturation of some of these antibodies.

Specific desensitisation may be produced orally, intradermally, or subcutaneously. The oral method is useful with children, who are most commonly sensitive to substances like egg, milk, wheat, and fish. In a case sensitive to egg, for example, the patient is put on a diet containing no egg for 14 days and given daily a mixture containing acid. hydrochlor. dil., ʒiss., and pepsini glycerinum, ʒi., in a tumbler of sweetened orange juice and water. At the end of a fortnight one drop of egg-white is added to this mixture, and later two drops. Gradually the dose of egg-white is increased up to ʒi., and by the time the patient can take this amount of egg-white in the mixture he can generally tolerate the amount of egg usual in a normal diet. I am sure that the hydrochloric acid mixture helps in the process of desensitisation.

In desensitising a patient by the intradermal method, better results seem to be obtained if the injections are multiple. An extract of the specific substance, just sufficiently strong to produce a wheal when given intradermally, is prepared. The patient is taught to prick himself with a sterilised sewing-needle, and to rub one drop of the extract into the wound. He performs this operation twice daily until a wheal ceases to appear on application of the extract. He is then provided with a slightly stronger concentration of the extract, and repeats the process. The strength of the extract is gradually increased until no wheal is produced, even with high concentrations.

The subcutaneous method is often useful in cases of asthma due to house dust. Dust from old houses light, a helpful but not confirmatory test, though of much value if pus has already been detected in the middle meatus. Puncture-irrigation is, however, the only reliable test. A fine trocar and cannula is passed through the inner antral wall, generally beneath the inferior turbinal, the trocar is withdrawn, a syringe affixed to the cannula, and the sinus washed out with warm normal saline solution. Others pass a suction-syringe through the inner wall *above* the inferior turbinal, inject a sterile saline solution, and by suction remove the contents of the antrum both for diagnostic and bacteriological purposes.

The basic principle of treatment is to provide an opening in the lower part of the inner antral wall which will ensure free, spontaneous, and permanent drainage. The best operation is that introduced independently by Caldwell, Luc, and Spicer. The canine fossa is exposed, and its bony wall removed so that the interior of the antrum can be thoroughly inspected and diseased tissues removed. A counter-opening is next made by removing the whole of the inner antral wall below the attachment of the inferior turbinal. The bucco-antral wound is then closed. In children and young adults with sound teeth, and also in adults when there is no ethmoidal complication, the naso-antral opening can be made by brazing inwards the inferior turbinal, and then by suitable punch-forceps, removing the lower half of the inner antral wall. If the infection be caused by a septic tooth, the antrum should be entered through the canine fossa because there will often be found a mass of septic granulations above the focus of dental infection, and this could not be efficiently dealt with by way of the nasal cavity.

Ethmoidal suppuration is frequently present to some degree in cases of chronic antral suppuration because infection from the latter is so liable to enter the closely adjacent anterior group of ethmoid cells. In such cases there is a tendency for polypi or other mucous membrane hypertrophies to form, and these would increase the nasal obstruction. The extension of suppuration through the ethmoidal labyrinth may eventually bring about much increase of the nasal discharge accompanied by increased headache. In such cases infection will frequently involve the frontal sinus, and graver issues, fortunately uncommon, will arise should it gain access to the orbit and its contents or to the meninges.

The diagnosis of suppurating ethmoiditis would be established by the quick recurrence of purulent discharge when the cells are probed after the antrum has been thoroughly cleansed by puncture irrigation. The operative treatment of ethmoiditis not only requires, but demands, a very detailed knowledge of the anatomy and pathology of the region. Its intimate anatomical relationship to the orbit and its contents, to the meninges by way of the cribriform plate and the dural sheaths of the olfactory nerve expansions make it a very dangerous region for any but the skilled and experienced nasal surgeon. More deaths have occurred after surgical treatment of the ethmoid than have followed all other intranasal operations put together.

Here I must stop, without discussing the symptoms, diagnosis, and treatment of suppuration in the frontal and sphenoidal sinuses. On this occasion it is unnecessary to attempt to do so, for when a chronic purulent discharge is caused by a combined infection of all the sinuses, the differential diagnosis of their share in the condition is one which is always difficult. Its surgical treatment demands the most careful manipulations and, above all, a conscientious regard for the safety and sanctity of human life.

PROSTATIC OBSTRUCTION, WITH SPECIAL REFERENCE TO PER-URETHRAL OPERATIONS

(MR. E. W. RICHES)

PROSTATIC obstruction of some degree is one of the commonest affections of men of advancing years, but one which is readily amenable to treatment. Prognosis depends largely on the amount of renal damage, the nature of the prostate encountered, and to some extent on the type of operation performed. The duration of symptoms is some index of the amount of renal damage; as regards the nature of the prostate, the most important distinction is between malignant disease and benign hypertrophy, and, in the benign types, between the adenomatous or glandular enlargement and the fibrous prostate. The type of operation performed must depend on the general and local condition of the particular patient, and with the methods now available it should be possible to select the optimum treatment for each case.

The earliest symptoms are some increase in frequency of micturition, necessitating urination once or twice during the night, and a less forcible stream, with a little delay in starting and terminal dribbling. These are often disregarded by the patient, and it is not until frequency and difficulty become acute, micturition becomes painful, or acute retention or hæmaturia supervenes that he presents himself for treatment. Perhaps it is for his ultimate benefit if an exposure to cold, or alcoholic excess, precipitates these late symptoms and so leads him to seek advice earlier.

Examination of the early cases must be complete, and as rectal palpation so often fails to reveal the true state of affairs the examination must include cystoscopy. Intravesical projection of the prostate may be slight, but the amount of trabeculation in the bladder is an index of the degree of obstruction; the volume of residual urine should be ascertained at the same time. The passage of a cystoscope is often followed by a considerable temporary improvement in urinary function, the degree of which may be an indication for further treatment by dilatation before any operative intervention is desirable.

Despite improvements in technique and after-treatment the mortality of suprapubic prostatectomy is still high, post-operative complications are not uncommon, and the results in certain cases are not entirely satisfactory. We must therefore be ready to consider the possibilities of *per-urethral methods* of treatment, interest in which has been recently revived in this country. The credit for being the first to suggest the division of obstructions at the bladder neck by this route goes to Guthrie, an English surgeon, who, as early as the beginning of the nineteenth century used a knife concealed in a catheter for the purpose. Subsequent developments have come from France, Italy, America, and England, and at the present day there are instruments with which such obstructions can be seen and removed, and this without the excessive bleeding which frequently accompanied the earlier procedures. This advance has been made possible owing to the development of the diathermy current by means of which tissue can be coagulated, or cut with little bleeding, the term endothermy being sometimes given to the cutting current. Modern instruments fall into two main classes:—

(a) The coagulating type, with which the obstructing tissue is first coagulated by diathermy and then removed with a punch, or left to slough away.

inorganic colloids. Very contradictory results have been reported both in the treatment of human cancer and in the experimental study of transplantable animal tumours. In a paper entitled The Influence of Vital Dye-stuffs and of Metallic Colloids on Resistance to Transplantable New Growths. Dr. Ludford discusses the results of an experimental investigation of this problem. The successful transplantation of an animal tumour is, in effect, an experimental metastasis formation. One of the first results of the experimental investigation of cancer was a demonstration by Bashford, Murray, and Cramer, that there was in the normal organism a resistance to this experimental metastisation and that this resistance could be enhanced in various ways. Later workers have applied the term "immunity" to this condition, a term which is held to be misleading since cancer will arise as readily in an "immune" animal as in a normal animal, and since the induction of so-called "immunity," after a tumour has established itself, will not affect the growth of such a tumour. Dr. Ludford shows that this condition of resistance can be lowered by the injection of trypan-blue. This indicates that in the chemotherapy of cancer by colloids overdosage may be dangerous by diminishing the resistance to metastatic spreading. This effect is probably due to an interference by the colloids with the function of the cells of the lymphocyte and monocyte series, which da Fano, from his cytological analysis of the reaction occurring in resistant animals, believed to have an intimate connexion with the development of resistance.

This argument is carried further in a paper by Dr. Foulds in which he compares the metastatic spread of a transplantable rabbit tumour, the Brown-Pearce carcinoma, in normal animals and in animals injected with trypan-blue. This tumour shows, like many human tumours, a predilection for certain sites, as exemplified by the frequency of metastasis in the kidneys, adrenals, and eyes, while liver and lung are less frequently affected, and the spleen is very rarely the seat of metastases. This predilection manifests itself not only when the primary growth is in the leg or testis, but even when the emulsion of tumour cells is injected intravenously. In animals which have received injections of trypan-blue metastases appear much more frequently, not only in those organs where they are usually found (kidney, adrenal, eyes), but also in the liver and lung, and frequently even in the spleen. These experiments demonstrate in a striking manner the existence of a definite resistance, residing in the different organs, and varying from organ to organ, to the deposition of metastatic emboli. The freedom of an organ from metastasis does not necessarily mean that cancer cells have not reached that organ, but may be due to the organ preventing such cells from establishing themselves there. The fact that this resistance to metastatic spread can be broken through by affecting the macrophage system is of considerable importance for the chemotherapy, and also for the radiotherapy of cancer.

RADIOTHERAPY IN PRECANCEROUS CONDITIONS

The action of radium on normal and malignant tissues is the subject of five papers.

It is known that radium may induce cancer, and it has also been asserted on clinical grounds that irradiation of malignant growths may sometimes have a stimulating effect on cancer cells. It seems therefore that irradiation of a precancerous condition might precipitate the development of malignancy. Dr. W. Cramer has investigated this question by producing experimentally a precancerous skin area by a limited course of tar painting, and then subjecting it to therapeutic doses of radium. This treatment was followed by a delay or even a complete inhibition of a subsequent development of skin cancer. In no case was there any evidence of a stimulating effect by radium. The result is held to be of practical importance in showing that radiotherapy is strongly indicated in precancerous conditions, and that in suitable doses it does not involve any risk. In previous experimental work on the development of malignancy in a precancerous skin area, Dr. Cramer had pointed out that such precancerous conditions may exist in human cancer in the area in which a malignant growth has made its appearance, but extending far beyond the growth itself. If the growth only is destroyed by irradiation a new tumour may arise therefore from the precancerous area which has not been irradiated. That may happen soon, or 10 or even 20 years later. Clinically such a development of a second growth is generally regarded as a local recurrence of the first growth, and is interpreted as indicating that the first tumour has not been completely irradicated. Surgical experience has shown that these so-called local recurrences can be avoided by excising as wide an area of tissue as possible surrounding the growth, or in the case of the breast the whole organ. For this reason Dr. Cramer holds that radiotherapy also should aim at irradiating not only the growth, but the area in which it has arisen, and his experiments demonstrate that such a procedure does not involve the danger of precipitating the development of a new tumour.

SELECTIVE ACTION OF RADIUM

The remaining four papers deal with the mode of action of radium on malignant cells and the attempt to answer the question whether there is any evidence for the alleged selective action of radium on malignant cells compared with normal cells. Since cancer cells differ in their metabolism from most normal cells by their power to split glucose into lactic acid, both in the presence and absence of oxygen, it seemed possible that radium had a selective action on this glycolytic mechanism. Mr. H. G. Crabtree has tested this point by exposing slices of transplantable tumour in vitro to the action of radium and studying the effect of their metabolism. In a long series of experiments he shows that, contrary to expectation, the glycolytic mechanism is very resistant to the action of radium—much more so than the respiratory mechanism—and that the latter is affected equally in both normal and malignant cells. There is therefore no indication of a differential action by radium on the metabolism of cancer cells, and the results do not support the contention that cancer cells are inherently more vulnerable to radiation than normal cells.

In another paper Mr. Crabtree has studied the inactivation of a relatively simple chemical system—an oxidase system—by radium. He finds that the dose of radiation required to produce partial inactivation of the enzyme is several times greater than that required to destroy the metabolism of living cells, and that for this system β and γ radiations produce the same effect, differing only quantitatively.

The finer cytological changes taking place in irradiated cancer cells have been studied in detail by Dr. Ludford. He compares the effect on the cells of two different mammary carcinoma strains—the more differentiated strain 27, and the less differentiated and more rapidly growing strain 63—and of a rapidly and furniture is often responsible for asthma and gives positive skin reactions, but street dust rarely produces skin reactions. To make the necessary extract, a portion of dust from the patient's house is shaken up with ether to remove fats, and then mixed with a small quantity of Evans's solution, an alkaline buffered saline solution. It is left to digest for 24 hours and is then dialysed. The concentrated fluid left after dialysis is filtered through a Seitz filter to get rid of any organisms left by the ether, and a culture is subsequently made from it to ensure that it is sterile. It is then made up in dilutions ranging from 1 in 10 to 1 in 100,000. It has been found that these specific substances are inactivated by boiling, are non-dialysable, and resist digestion by trypsin. If the patient gives a skin reaction with a 1 in 10,000 dilution of the extract applied intradermally, it is wise to begin with a small dose of the 1 in 100,000 solution subcutaneously. This method is worth trying on the perennial asthmatic who is better out of doors or away from home. The trouble is that the extracts are expensive to prepare, and a patient has been known to move into a new house and make a complete recovery just as the extract was ready for trial.

For *non-specific desensitisation* old tuberculin (T.O.A.) is a valuable agent. The chief thing is to avoid giving too big a dose; it is advisable to begin with a very small dose and to work up until a reaction is obtained, after which the dose should not be increased further but kept at the same level. Another method of non-specific desensitisation is by autohæmotherapy; 5 c.cm. of blood are withdrawn from the patient's arm and reinjected immediately into the buttock; the amount of blood withdrawn at each treatment is increased until about 40 c.cm. are being drawn off and reinjected. This method occasionally keeps the patient free from asthma for about three or four months.

"Proteose" is used to desensitise patients by G. H. Oriel at Guy's Hospital. Proteose is a protein derivative easily extracted from the urine of the patient by ether. A certain number of cases do well under this method, and though I have not been able to secure quite the same results as those obtained at Guy's, I have seen some of the cases treated there, and am convinced that there was something in the use of proteose.

Vaccines are sometimes useful; in patients whose asthma has followed an attack of bronchitis, the anticatarrhal vaccine prepared by Parke, Davis and Co. can be used, but it is important to begin with a minute dose. Patients with asthma are far more sensitive to a dose of vaccine than is a normal person, and the preliminary dose should not exceed one-hundredth of the dose recommended for normal people.

SPECIAL ARTICLES

EXPERIMENTAL INVESTIGATION OF CANCER

IMPERIAL CANCER RESEARCH FUND'S REPORT

VITAL staining and the radiotherapy of cancer are the two main subjects considered in the nine papers forming the tenth scientific report of the Imperial Cancer Research Fund. Although at first sight these two lines of investigation seem to be independent of each other, the report shows that conclusions derived from one have an important application to the other and more generally to the chemotherapy of cancer.

VITAL STAINING

When an acid dye such as trypan-blue is injected into a living animal, dye droplets make their appearance in certain of the cells—particularly in the macrophages, where they accumulate in larger droplets, and also in the cells of the connective tissue and of the liver and kidney. No droplets appear in epidermal, gland, or germ-cells. This process of vital staining may be produced, as it is especially in the macrophages, by a phagocytosis of the dye droplets, or it may be the result of the passage of the dye into the cells which then actively segregate the dye; and it is difficult sometimes to distinguish between these two processes. Dead cells, or cells undergoing degenerative changes, such as keratinisation, also stain with trypan-blue; but this is a more diffuse staining produced by a passive coloration and is easily distinguished from the two forms mentioned above.

In a series of papers previously published Mr. R. J. Ludford, D.Sc., has discussed this process in detail, with special reference to the difference between normal cells and malignant cells, by injecting trypan-blue into mice and rats with spontaneous or transplantable tumours. He found that malignant cells, unlike their normal prototypes, remain almost entirely unstained. This distinction is particularly clear between normal fibroblasts which segregate the dye and sarcoma cells which do not, and also between normal and malignant mammary cells. The distinction also exists between normal and malignant cells of the skin, but it is here more a difference in degree than in kind. These observations have been carried further in two papers published in this report by Dr. Ludford and by Dr. Leslie Foulds. Dr. Foulds, in observations on six varieties of filtrable tumours of the fowl, found that the cells of five sarcomata or fibrosarcomata behaved like the sarcomata of mice or rats; they did not segregate trypan-blue under conditions which lead to its active segregation by histiocytes and fibroblasts. The sixth tumour, an endothelioma, showed, however, areas of cells containing relatively large masses of dye, while in other parts of the tumour the cells were free from dye droplets. Where this massive accumulation took place it was interpreted as being due to active phagocytosis and not to segregation.

Dr. Ludford has extended his observations to normal and malignant cells cultured in vitro in a medium to which trypan-blue had been added. The results confirm his previous observation that cancer cells do not segregate trypan-blue in the same way as their normal prototypes. In tissue culture of malignant cells it is difficult to distinguish between the malignant cells and the macrophages which wander out from the explants. The method of vital staining in vivo affords a means of distinguishing between the two since the macrophages stain intensely while the malignant cells do not.

The phagocytosis by certain cells of the body, especially the macrophages, of colloidal particles of a dye such as trypan-blue resembles in many respects the phagocytosis by them of particles of inorganic colloids. This is a phenomenon usually described as "blockade of the reticulo-endothelial system." In recent years attempts have been made to use this phenomenon in the chemotherapy of cancer by the injection either of dyes such as isamine blue or of by Dr. Y's legal representative, Dr. O'Donovan said that the perforation might have been made by a skilled person acting clumsily and might have been made by the patient herself. In his summing-up the coroner expressed the opinion that the woman's injury was not self-inflicted; he did not think anyone would inflict such an injury upon herself when about to go into a nursing home. Referring to the evidence, the coroner commented on the books kept by the nursing home. The matron of the home had previously said that one of the books containing particulars of her patients became so dilapidated that she and her secretary copied its contents into a new book; she had destroyed the dilapidated book; she had finished the copying-out after Mrs. Tremlett's death. She was questioned also about another patient (Miss B), and agreed that Miss B entered the nursing home on July 26th and not August 1st as originally entered. Miss B was also, it appeared, one of Dr. Y's patients; he had paid £10 for her. It was in connexion with Miss B's case that Dr. Y cut off the tops of his case-book pages. She complained, said Dr. Y, that the police had visited her; he then realised that her name was on the back of the page which he had given to the coroner's officer. "Therefore, before the officer arrived, I deleted from the book anything that might permit me to give away any further confidence; I did not consider a medical man should do so; his confidence with his patients should be as sacred as the confessional." Dealing with this aspect of the case, the coroner observed that, while he could understand a doctor regarding his case-book as sacred, and even that he should cut the tops off the pages, he could not understand why he should burn the tops. Unless Dr. Y thought he was deriving some protection from that, it seemed a very peculiar thing to do. As for the nursing home he would have liked to have said that it was free from any possible adverse comment, and he did not want to be understood as making any serious adverse comment about it except that there were considerable errors in the books. "I am going to return an open verdict," concluded the coroner, "which will leave the way clear for others dealing with such matters as death certificates and the keeping of registers to decide whether the facts brought to light here involve any action on their part."

UNITED STATES OF AMERICA

(FROM AN OCCASIONAL CORRESPONDENT)

TUBERCULOSIS IN NEW YORK

In spite of the rapidly declining death-rate from tuberculosis, this disease still takes a toll of over 5000 lives yearly in the city of New York. More than 30,000 cases of active tuberculosis are known to the city health department. The city hospitals care for some 12,000 cases each year.

In a recent analysis of the tuberculosis problem in New York, Louis I. Dublin, president of the American Public Health Association, pointed out that the present death-rate from all forms of tuberculosis in New York City (73 per 100,000 in 1930) is approximately one-quarter of the rate for 1900. He drew attention to the disparity of death-rates at the present time in various boroughs of the city. "The people who, when they lived in Manhattan, on the East Side of the city, showed, uniformly, rates of 150 and up to 200 per 100,000, seem to have left their tuberculosis behind them after moving to the Bronx (57); or to Brownsville, where the rate is only 36." The explanation is not only the improved housing conditions of the newer boroughs; there is an element of selection in those who lift themselves out of congested Manhattan. Dublin believes, however, that of the various factors making for the lower rates, housing is the most important.

A new racial group, the Porto Ricans, have recently made themselves at home in New York, and are helping to maintain the tuberculosis death-rate. Some 100,000 of them are said to live just beyond the "coloured belt" in Lower Harlem. One tuberculosis specialist, who holds a clinic at Mount Sinai Hospital, says that Porto Ricans constitute three-quarters of his patients there. Miss Whitney, statistician of the National Tuberculosis Association, has discovered that of 700 young women who died of tuberculosis in 1930 in New York 34 were Porto Ricans. This gives a death-rate for this racial and age-group four times that of the corresponding age-group in the general population.

A LABORATORY OF PUBLIC HEALTH ADMINISTRATION

Baltimore City is establishing in the sixth and seventh wards of the city a new health district which will be a training area for the Johns Hopkins School of Hygiene. This area contains the hospital as well as the new buildings of the school of hygiene. The director of this training area, who will also be a deputy officer of the Baltimore city health department, is to be Dr. H. S. Mustard. He will come to his new duties from the State health department of Tennessee, where he has been assistant commissioner of health. Dr. Mustard has had experience in private practice, with the U.S. public health service, as director of a national demonstration county health unit, and as a teacher of public health in Vanderbilt University.

FEDERAL RELIEF PROJECTS

To meet the emergency created by economic distress and unemployment in the coming winter certain funds have been made available by Congress, to be administered by a bi-party board, the Reconstruction Finance Corporation. $300,000,000 is available for direct relief provided that the governor of each State makes application and the Corporation satisfies itself that the State is making adequate efforts to cope with the need for relief out of its own resources. Some States have already been refused aid on the ground that their own efforts are inadequate.

A further $1,500,000,000 is available for loans on self-liquidating projects. Municipalities and boards of county commissioners may borrow from this fund as well as private enterprises. Apparently schemes for the construction of water-supply or sewerage systems may be financed by this fund, and an opportunity is thus created to advance the public health while at the same time relieving unemployment.

RESEARCH IN CAUSES OF MATERNAL MORTALITY

In the recent report of the New York State Health Commission a recommendation was made that the State health department investigate for at least one year every maternal death, outside the city of New York, in coöperation with local medical societies, to the end that avoidable factors in maternal mortality might be determined. This investigation is being pursued with diligence. The department transfers to a special form all data that are available from the death certificate. The form is then forwarded to a local representative, who makes every effort to get complete information. It is hoped that by making the investigation while circumstances surrounding the death are still fresh in the minds of attending physicians, valuable information may be obtained.

growing sarcoma strain. In addition, the effect on normal mammary cells of lactating mice was observed. The changes in the nuclear and cytoplastmic constituents are described in detail and illustrated by numerous text-figures. The general conclusion is arrived at that the primary effects of irradiation on the colloidal state of the protoplasm are probably the same in all cells, as well as a concomitant inhibition of mitosis, but the capacity of recovery as well as the later changes differ widely with different types of cells. This applies both to normal and malignant cells. The greater outburst of mitotic activity, after irradiating the more rapidly growing tumours, probably results in a larger number of non-viable daughter cells, and hence greater cell-destruction. It is however recognised that the direct cellular changes do not adequately account for the complete regression of malignant growths after irradiation, and that irradiation has no specific action upon cancer cells as such.

GENERAL THERAPEUTIC EFFECT OF RADIUM

Lastly, in a paper entitled Experimental Observations on the Therapeutic Action of Radium Dr. Cramer raises the question whether in addition to the local action there is a general therapeutic effect of irradiation, as has been suggested. He records experiments which appear to rule out completely this suggestion of a general therapeutic effect. This is followed by a discussion whether the local action of radiation is due entirely to the destructive action of radium on the malignant cells by some selective action, or whether there is in addition some other indirect effect which forms an essential part of the therapeutic action of radium. He shows that a dose of radiation sufficient to ensure regression, if the tumour is left in situ, does not directly destroy all the malignant cells of this tumour, because these irradiated cells will again give rise to new tumours if removed immediately after irradiation and inoculated into new animals. But although these cells have not all been killed they have been damaged; for the tumours obtained by inoculating these irradiated cells grow more slowly than the tumours from non-irradiated cells. If an interval of several days is allowed to elapse between irradiation and subsequent transplantation, the number of tumours formed from the inoculated irradiated cells diminishes, and it is only about eight days after irradiation that the inoculations give consistently negative results, indicating that the irradiated cells are now dead. Moreover, irradiation in vitro, where a very thin slice of a tumour is exposed to radium so as to ensure a complete irradiation of every cancer cell under optimal conditions, requires a dose which is not, as one would expect, smaller but rather larger than that necessary to produce regression of a whole tumour in vivo. From experiments such as these it is concluded that the assumption generally made at present—that every malignant cell has to be destroyed by a direct local action in order to bring about the regression of malignant neoplasm—is not valid. Some additional process must take place in the irradiated tumour which contributes to the eventual destruction of a malignant growth. By a further analysis of the changes following irradiation it is shown that both in normal and in malignant tissues irradiation damages not only the parenchyma but also the connective tissues, and especially the blood-vessels. This damage is followed by the usual reaction of repair in which the invasion of the damaged parenchyma by numerous macrophages is an outstanding feature. Illustrations are given of this invasion of irradiated tumours by macrophages which attach themselves to the damaged malignant cells, and of the subsequent formation of fibrous tissue, probably from these macrophages, which completes the regression of an irradiated tumour. This conception, which is in agreement with such recent observations as those of Dr. B. D. Pullinger on human material,[1] where the damage done to the blood-vessels has been particularly emphasised, should materially influence our conceptions of the rationale of radium therapy.

The report contains, in addition to over 200 printed pages with numerous text-figures, 55 plates, many of which are coloured. As Dr. J. A. Murray, F.R.S., the director of the laboratory, points out in the introduction to the report, the free use of monochrome and coloured figures, each with a complete legend, obviates the necessity for lengthy verbal descriptions of details in the text, and for most readers the summary and the plates will be sufficient. The report reflects the patient, careful work which characterises the research carried out in the laboratories of this Fund and indicates the wide scope and importance of its activities.

MEDICINE AND THE LAW

A Question of Destroyed Case-notes

DURING an inquest at St. Pancras a doctor explained to the coroner that he had cut off the upper part from all the pages but one in his case-book, and had burned the pieces in order to avoid being in a position to disclose his patients' secrets. The inquest, opened on Sept. 2nd, resumed on Sept. 20th, and concluded on Oct. 7th, concerned the death of Mrs. Tremlett, a woman aged 28, who died in a nursing home. In his final summing-up the coroner (Mr. Bentley Purchase) described the case as one of considerable complexity and importance. The names of two medical practitioners, to whom it will be convenient to refer here as Drs. X and Y, had been mentioned. Dr. X said that he had advised the deceased to see a gynæcologist and that she had herself then mentioned Dr. Y. The patient then entered a nursing home where she died after an operation. When Dr. Y told the husband that his wife was dead, the husband said it was the first time he had heard that his wife had been pregnant. A certificate (not a death certificate), produced during the proceedings, was described by Dr. X as a forgery. Dr. Y, said the coroner, gave the husband a death certificate, "and, if that certificate had been accepted, this inquiry might never have begun." The coroner had pointed out to Dr. Y that the death certificate did not mention the word "operation." Dr. Y explained that it was the first death certificate he had signed for years, and he was rather puzzled about it; it never occurred to him to mention the operation. Dr. M. J. O'Donovan, who conducted a post-mortem examination in the presence of Dr. Y, stated that the anæsthetic and the operation were terminal aggravating factors of the patient's death. There was a perforation which must have occurred 12 hours before the operation. Dr. Y, he said, seemed surprised when the perforation was discovered; Dr. Y called on him next day and seemed anxious to convince him that the perforation had been made at the time of the operation. Dr. Y's own version of this, in the witness-box, was that Dr. O'Donovan said something about some injury caused by a knitting-needle or some other instrument, but that his own opinion was that this could not possibly have been the cause of death. Answering a question medical man on the Commission was a guarantee that the medical point of view would not be ignored, and in recent years the attitude of the Commission, while impartial, was not unsympathetic with the profession. There is a possibility that under the new arrangements the medical considerations may not be given as much weight as in the past.

ROYAL ACADEMY OF MEDICINE IN IRELAND

The annual general meeting of the Royal Academy of Medicine in Ireland was held on Oct. 3rd, when the annual elections of officers and councils took place. Prof. Thomas G. Moorhead was re-elected president; Dr. T. P. C. Kirkpatrick, general secretary and treasurer; and Mr. W. Doolin, secretary for foreign correspondence. The following presidents of sections were elected:—Medicine: Dr. W. G. Harvey. Surgery: Mr. Henry Stokes. Pathology: Dr. J. McGrath. Obstetrics and gynæcology: Dr. G. Tierney. Anatomy and physiology: Prof. W. J. Jessop. State medicine: Dr. J. P. Shanley. Laryngology and otology: Mr. P. Dempsey.

THE LATEST HOSPITAL SWEEPSTAKE

The drawing for the Irish Hospitals Sweepstake on the Cesarewitch took place last week. It was announced that the total sums received amounted to £3,624,448. This is less by about £500,000 than that received for the last sweep—that on the Derby. Hitherto, each sweepstake has shown an advance on its predecessor. The minimum sum to reach the hospitals in the present case will be £724,889, of which two-thirds will go to the voluntary hospitals.

MEMORIAL TO SIR ANDREW BALFOUR

ON Thursday in last week the Earl of Athlone, Chancellor of the University of London, unveiled a memorial tablet to Sir Andrew Balfour, the first director of the London School of Hygiene and Tropical Medicine. The meeting was presided over by Sir Holburt Waring, P.R.C.S., chairman of the Court of Governors of the School, who briefly explained the origin of the movement. The School Council, he said, decided on the death of Sir Andrew to erect a memorial tablet in the school and create a fund to enable students, preferably from overseas, to study at the School. An influentially signed letter had brought in up to date the satisfactory sum of £1200, while in addition, said Sir Holburt, a promise of a bequest of £1000 had been received. The execution of the memorial tablet was, he said, entrusted to Mr. Allan Howes.

The wording of the memorial tablet, on which appears in bas relief the portrait illustrated above, is as follows:—

A TRIBUTE OF GRATITUDE AND AFFECTION
TO
ANDREW BALFOUR
K.C.M.G., C.B., M.D., LL.D., F.R.C.P.
(1873–1931)
IN MEMORY OF HIS DEVOTION TO THE
CAUSE OF TROPICAL HYGIENE AND OF
HIS SELF-SACRIFICING LABOURS AS
DIRECTOR OF THIS SCHOOL
"THROUGH THE BATTLE, THROUGH DEFEAT,
MOVING YET AND NEVER STOPPING,
PIONEERS! O PIONEERS!"

Lord Athlone then delivered a brief address on Andrew Balfour's character and work, describing him as "a man of a thousand enduring qualities and for every such quality he drew to himself a thousand friends." He outlined Balfour's professional career, instancing his successes, and continued:—

"When the South African war broke out we find him on duty in the pestilential typhoid camp at Pretoria, where he himself suffered from a severe attack of the disease. On his return from that campaign he came under the influence of Patrick Manson and devoted himself to the cause of tropical medicine and hygiene. There followed the first great step in Balfour's career in that field. In 1902 he was appointed director of the Wellcome Tropical Research Laboratories at the Gordon College in Khartoum and medical officer of that city. There is no finer record than the work of Balfour during the 10 years which followed. He transformed the dusty, ill-kept, insanitary mud-huts of the Khalifa into a model town, and banished malaria entirely from its precincts. . . During the war he served in France, Salonica, Egypt, and East Africa with the rank of Lieut.-Colonel R.A.M.C. He was a member of the Medical Advisory Committee of the Mediterranean War Area (1915–16), President of the Medical Advisory Committee Mesopotamia (1916–17), and President of the Egyptian Public Health Commission (1918). . . . To the work which was, alas, to prove the last of his labours—the building, the equipment, the organisation of this great school —Andrew Balfour brought the same passionate zeal, the same untiring energy which were characteristic of his whole career, and his inspiring personality is so very fresh in the minds of all of you that of his last great piece of work there is hardly any need to speak. The appointment of Andrew Balfour to be the first Director of this School gave to the School from its very inception a splendid introduction throughout the whole world and contributed perhaps more than anything else to the reputation which it has already established. Balfour was not only a great worker, but what is in my judgment perhaps quite as valuable, he was a great sportsman. You all know how, from the days when he threw his weight into the scrum of the Rugby International until the day of his death when he was President of the Scottish Rugby Union, his love for the game was one of the great passions of his life. Again, he was a prolific writer and lecturer, and as relaxation from the sterner stuff of life he found an outlet for his enthusiasms in the writing of novels of no mean order. Finally, and in a word, Balfour was a great Empire builder. And when I say this I am thinking not so much of his devotion to work, of his vast knowledge and contributions to the subject of Empire health, not of his academic distinctions, not of his contributions to sport and literature, but of his fine character. He was without guile, honest to the core, a man who evoked in his colleagues a spirit of love and sacrifice . . . It is fitting that on the memorial which I am now to have the honour of unveiling, there

Preliminary conclusions from this study may be published early in 1933.

A similar study was undertaken in the city of Denver, Colorado, in 1930, both for maternal and infant deaths. The number of the former was, however, too small to yield conclusions of much statistical significance.

BUDAPEST

(FROM OUR OWN CORRESPONDENT)

TRACHOMA IN HUNGARY

IN the southern parts of Hungary trachoma was prevalent as long ago as the middle of last century; in some districts it took a definite endemic form. A campaign against this scourge was started early in this century by Prof. Emile de Grosz, who organised the following scheme :—

1. Provision for continuous observation of all trachoma cases by means of (*a*) notification; (*b*) ophthalmological examination in schools, factories, and tenements, offices and military barracks, and of apprentices, domestic servants, demobilised soldiers, and recruits; (*c*) examinations of the eyes of the general population, this last being an emergency measure to be applied only on demand by the central authorities.
2. Free treatment in trachoma dispensaries, of which there were eight in the country; the medical service to be supplied by local practitioners for a fixed honorarium originally consisting of 100 crowns a month. The treatment carried out by these practitioners to be under the supervision of the medical officer of health, or of an ophthalmologist.
3. Improvement of hygienic conditions in schools, factories, and workshops; the foundation of industrial colonies in trachoma-stricken districts, in order to check the movement of trachomatous workers, and the support of the families of incapacitated trachoma patients. Soldiers suffering from trachoma to be treated in military hospitals.
4. Stimulation of research into the pathology and treatment of trachoma by means of grants and prizes, and instruction of the public by means of occasional popular lectures and courses.

These efforts bore fruit. In several cities special trachoma hospitals, wards, and eye dispensaries were erected until there were 1200 beds available for trachoma patients alone. In 1911, previous to Prof. Grosz's appointment, 12 experts and 90 parish doctors had been entrusted with the treatment of patients. Prof. Grosz succeeded in persuading the military and civilian authorities to work hand in hand. The Act of Conscription of 1913 contained the provision that those suffering from trachoma, yet otherwise fit for military service, should be placed in a hospital managed by specialists three months prior to the regular time of enlistment. Those who were cured joined their regiments, while those who were incurable were referred to a superior authority. The campaign against trachoma was reasonably successful up to the outbreak of the war. Patients with trachoma at the dispensary of the Budapest university ophthalmological clinic had been reduced from 7·2 per cent. in 1891 to 2 per cent. in 1910, under the schemes organised in 1883 by Prof. Feuer, and the reduction continued under the régime of Prof. Grosz. During the late war trachoma regiments were formed. The official report of these troops, which had been engaged in action, showed that 78·5 per cent. were cured, 21·2 per cent. still required treatment, and only 0·3 per cent. were certified as unfit for military service. With a view to the future release of the men on demobilisation the leaders of the campaign adopted extensive precautionary measures. The men from the trachoma wards were, however, scattered and thus carried the disease to areas hitherto immune. In 1924 the surgeon-in-chief of the army compiled a map on which the soldiers suffering from trachoma were grouped according to the districts to which they belonged. The map showed that the disease was prevalent all over the country.

In 1926 new inquiries were made in schools, institutes, prisons, factories, and tenements. The result was that, of 8,500,000 inhabitants, 10,000 trachoma patients were brought to light. Of 824,984 school-children, 3257 were found to be suffering from trachoma. The treatment was then entrusted to competent physicians for whose emoluments the State assumed responsibility.

Statistics from the eye clinics are illuminating. In the dispensaries attached to these clinics, the number of trachoma patients in Budapest, in 1930, was 1·5 per cent., in Segedin (the second largest city in Hungary), 10 per cent., and in Debretzin and Fuenfkirchen, 5 per cent. respectively. The difficulty of the situation is shown by the fact that of the trachoma patients examined at the university eye clinic upward of 50 per cent. were suffering from pannus, so that the visual power was already endangered. In spite of the critical financial position of Hungary, the sum of 81,000 pengö (£4000) was allocated in 1930 to the campaign against trachoma, over and above the sum of about 245,000 pengö demanded by the hospitals. Even now the number of beds (316) available for the treatment of trachoma patients in post-war Hungary is entirely inadequate.

IRRADIATION OF THE SPLEEN FOR MENORRHAGIA

At a recent meeting of Hungarian radiologists Dr. Horvath stated that he uses irradiation of the spleen as routine treatment in cases of obstinate menorrhagia and metrorrhagia, and in other cases of intractable hæmorrhage. He attributes the good results to the acceleration of the coagulation-time of the blood. His technique is as follows. In cases where the spleen is of normal size and in the normal position the patient lies on her right side, with the left arm raised high above the head. The actual size of the spleen is made out by percussion. X rays are then applied to the area corresponding to the splenic dullness over a field of about 20 × 15 cm. The focus skin distance is 30 cm., the other factors being 30 kw., 8 ma., with 5 mm. aluminium filter. The treatment is repeated after a lapse of four weeks, and if this does not prove sufficient, another exposure is given after three weeks. In general, not more than three or four irradiations are necessary.

IRELAND

(FROM OUR OWN CORRESPONDENT)

NATIONAL HEALTH INSURANCE COMMISSION

IT has been understood for some time that at least two of the National Health Insurance commissioners in the Irish Free State were likely soon to retire under the age rule of the civil service, and, in one case, it is understood that the operation of the rule had been temporarily postponed. It is now stated in the Dublin press that the three commissioners are about to retire on pension, and that in future the administration of National Health Insurance will be in the hands of an officer of the Department of Local Government and Public Health directly responsible to the Minister. The three commissioners, who have held office since the National Health Insurance Act came into force some 20 years ago, are Sir Joseph Glynn, chairman, Dr. W. J. Maguire, and Mr. Alfred Dickie. Although the medical profession has had its differences with the Commission from time to time, and particularly in the early years of health insurance, the change in administration will be regarded with some misgiving. The presence of a medical man on the Commission was a guarantee that the medical point of view would not be ignored, and in recent years the attitude of the Commission, while impartial, was not unsympathetic with the profession. There is a possibility that under the new arrangements the medical considerations may not be given as much weight as in the past.

ROYAL ACADEMY OF MEDICINE IN IRELAND

The annual general meeting of the Royal Academy of Medicine in Ireland was held on Oct. 3rd, when the annual elections of officers and councils took place. Prof. Thomas G. Moorhead was re-elected president; Dr. T. P. C. Kirkpatrick, general secretary and treasurer; and Mr. W. Doolin, secretary for foreign correspondence. The following presidents of sections were elected:—Medicine: Dr. W. G. Harvey. Surgery: Mr. Henry Stokes. Pathology: Dr. J. McGrath. Obstetrics and gynæcology: Dr. G. Tierney. Anatomy and physiology: Prof. W. J. Jessop. State medicine: Dr. J. P. Shanley. Laryngology and otology: Mr. P. Dempsey.

THE LATEST HOSPITAL SWEEPSTAKE

The drawing for the Irish Hospitals Sweepstake on the Cesarewitch took place last week. It was announced that the total sums received amounted to £3,624,448. This is less by about £500,000 than that received for the last sweep—that on the Derby. Hitherto, each sweepstake has shown an advance on its predecessor. The minimum sum to reach the hospitals in the present case will be £724,889, of which two-thirds will go to the voluntary hospitals.

MEMORIAL TO SIR ANDREW BALFOUR

On Thursday in last week the Earl of Athlone, Chancellor of the University of London, unveiled a memorial tablet to Sir Andrew Balfour, the first director of the London School of Hygiene and Tropical Medicine. The meeting was presided over by Sir Holburt Waring, P.R.C.S., chairman of the Court of Governors of the School, who briefly explained the origin of the movement. The School Council, he said, decided on the death of Sir Andrew to erect a memorial tablet in the school and create a fund to enable students, preferably from overseas, to study at the School. An influentially signed letter had brought in up to date the satisfactory sum of £1200, while in addition, said Sir Holburt, a promise of a bequest of £1000 had been received. The execution of the memorial tablet was, he said, entrusted to Mr. Allan Howes.

The wording of the memorial tablet, on which appears in bas relief the portrait illustrated above, is as follows:—

A TRIBUTE OF GRATITUDE AND AFFECTION
TO
ANDREW BALFOUR
K.C.M.G., C.B., M.D., LL.D., F.R.C.P.
(1873–1931)
IN MEMORY OF HIS DEVOTION TO THE
CAUSE OF TROPICAL HYGIENE AND OF
HIS SELF-SACRIFICING LABOURS AS
DIRECTOR OF THIS SCHOOL
"THROUGH THE BATTLE, THROUGH DEFEAT,
MOVING YET AND NEVER STOPPING,
PIONEERS! O PIONEERS!"

Lord Athlone then delivered a brief address on Andrew Balfour's character and work, describing him as "a man of a thousand enduring qualities and for every such quality he drew to himself a thousand friends." He outlined Balfour's professional career, instancing his successes, and continued:—

"When the South African war broke out we find him on duty in the pestilential typhoid camp at Pretoria, where he himself suffered from a severe attack of the disease. On his return from that campaign he came under the influence of Patrick Manson and devoted himself to the cause of tropical medicine and hygiene. There followed the first great step in Balfour's career in that field. In 1902 he was appointed director of the Wellcome Tropical Research Laboratories at the Gordon College in Khartoum and medical officer of that city. There is no finer record than the work of Balfour during the 10 years which followed. He transformed the dusty, ill-kept, insanitary mud-huts of the Khalifa into a model town, and banished malaria entirely from its precincts. . . During the war he served in France, Salonica, Egypt, and East Africa with the rank of Lieut.-Colonel R.A.M.C. He was a member of the Medical Advisory Committee of the Mediterranean War Area (1915–16), President of the Medical Advisory Committee Mesopotamia (1916–17), and President of the Egyptian Public Health Commission (1918). . . . To the work which was, alas, to prove the last of his labours—the building, the equipment, the organisation of this great school—Andrew Balfour brought the same passionate zeal, the same untiring energy which were characteristic of his whole career, and his inspiring personality is so very fresh in the minds of all of you that of his last great piece of work there is hardly any need to speak. The appointment of Andrew Balfour to be the first Director of this School gave to the School from its very inception a splendid introduction throughout the whole world and contributed perhaps more than anything else to the reputation which it has already established. Balfour was not only a great worker, but what is in my judgment perhaps quite as valuable, he was a great sportsman. You all know how, from the days when he threw his weight into the scrum of the Rugby International until the day of his death when he was President of the Scottish Rugby Union, his love for the game was one of the great passions of his life. Again, he was a prolific writer and lecturer, and as relaxation from the sterner stuff of life he found an outlet for his enthusiasms in the writing of novels of no mean order. Finally, and in a word, Balfour was a great Empire builder. And when I say this I am thinking not so much of his devotion to work, of his vast knowledge and contributions to the subject of Empire health, not of his academic distinctions, not of his contributions to sport and literature, but of his fine character. He was without guile, honest to the core, a man who evoked in his colleagues a spirit of love and sacrifice . . . It is fitting that on the memorial which I am now to have the honour of unveiling, there are engraved words which Andrew Balfour himself loved.

The Dean of the School, Prof. W. W. Jameson, then accepted with thanks on behalf of the Governors and the Staff, the memorial while expressing the indebtedness of all to Lord Athlone for his presence at the ceremony and practical interest in the affairs of the University of London.

PUBLIC HEALTH SERVICES

Increased Tuberculosis Mortality in Young Women

A noteworthy feature of the latest London mortality statistics[1] is the lack of decline in recent years in mortality from pulmonary tuberculosis amongst young women.

In his annual report for 1927 the Registrar-General of England and Wales pointed out that women of 15–35 years of age formed the only section of the population in which an improvement in mortality from phthisis had not been observed in recent years. The cause of this phenomenon has not so far been adequately explained, though it has commonly been attributed to the increase of young women in industrial and commercial employment. In London, according to the mortality-rates set out in this report, the phthisis mortality amongst women has actually risen between 1911–13 and 1929–31 by 23 per cent. at ages 15–20, and 30 per cent. at ages 20–25. At every other age, and at every age amongst males, a decline is registered. When these deaths from pulmonary tuberculosis, at ages 15–25, are stated as a percentage of the deaths, at the same ages, from all causes, it is found that London shows the greatest relative increase in phthisis, the rural districts of the whole country showing almost no change between 1911–13 and 1928–30. The suggestion is that in the rural areas the occupation of young women has not changed to the same extent as in urbanised areas. Yet when the London figures are considered in more detail by the comparison of two groups of boroughs—those representing the poorest population and those representing better-class areas with a low mortality-rate—it is found that the increase in pulmonary tuberculosis per cent. of all deaths among young women of 15 to 25 is much the same in both groups.

> "If change of employment from domestic work to commercial or industrial occupations or 'industrialisation' were alone the cause of the increased mortality from phthisis, the change should be far more conspicuous in the better class areas; for in these the occupation figures of the census years 1911 and 1921 show that, in the ten years intervening between them, the proportion of young women of this age engaged in domestic service decreased by nearly one-half, while in the poorer group of the population the number employed in domestic service is comparatively negligible in both censuses."

An analysis of further available data shows that practically the whole of the increase in mortality from pulmonary tuberculosis in London has been among single women. The obvious explanation that young women suffering from phthisis do not marry is insufficient to explain the considerable divergence between the single and the married. The possibility cannot be excluded that it is the young unmarried woman who is likely to be most adversely affected by economic conditions. As (judging by mortality-rates) their resistance to pulmonary tuberculosis in the early years of adolescence is less than that of young men, it is only to be expected that when adverse economic conditions are added at this period of life the young women will be much more affected than young men. If this is the explanation of the facts an improvement in economic conditions affecting young women wage-earners should be followed by a decline in this excessive mortality.

A factor which has not been considered in this report, but may affect London to a peculiar degree is internal migration. It has been shown[2] that in all probability the relatively *low* phthisis rates in the *urban* areas and the relatively *high* rates in the *rural* areas among young adults—especially women—are related to the migration of the more physically fit from the country to the town, the town mortality being lowered, the country mortality increased, by this movement of the healthiest. If, as there is some reason to believe, this selective migration to London has been slackening of recent years, the London mortality-rates, especially from phthisis, are likely to be swollen owing to this relative absence of healthier recruits. Though this might be a partial explanation of the abnormal rise shown in the London rates, it obviously fails to be a complete explanation, since, as has been pointed out, the lack of decline in pulmonary tuberculosis in young females extends to the whole country.

The problem is an important one, both to the social worker and the public health worker, and Sir Frederick Menzies has done well to draw special attention to it by this study of the London figures.

The Ex-Sanatorium Patient

In the same report to the London County Council Sir Frederick Menzies refers to the assistance given to tuberculous patients in obtaining employment after residential treatment. A scheme was adopted in 1928 which provides for the training for nursing and domestic service of selected patients at King George V. Sanatorium after a period of treatment and special observation at Pinewood Sanatorium. For men ex-sanatorium patients, two workshops for their employment have been established by the Central Fund for the Industrial Welfare of Tuberculous Persons. This work is still experimental, and the maintenance of the workshops is dependent to some extent upon a subsidy from charitable funds. In addition, in several boroughs, dispensary handicraft classes have been organised for those who are unfit for ordinary employment. The Council sends a number of patients to Papworth Village Settlement and to the Preston Hall Colony, a careful selection being made with a view to the admission of patients most likely to be accepted later as suitable for settlement, while at the Burrow Hill Colony training in gardening and clerical work is given to youths between the ages of 15 and 19 years. A scheme has also been adopted under which arrangements are made for special training to be given here to selected boys, with a view to their subsequent employment in the Council's parks department. In these ways remunerative employment is being found for a certain number of the Council's ex-sanatorium patients in an effort to reduce, even to a slight extent, the economic loss that this disease inflicts upon the community.

CORRESPONDENCE

THE GENERAL PRACTITIONER

To the Editor of THE LANCET

SIR,—I have read in the current issue of THE LANCET, with very great pleasure, Dr. E. K. le Fleming's inaugural address at St. George's Hospital and I am glad that he has brought up the subject of the general practitioner. This subject is one about which, in my own small way, I have been agitating for years. At the present time students become qualified and are launched into the world without any knowledge whatever of the very essentials of conducting a general practice successfully, and when I say successfully I mean both as regards the patients as well as regards themselves. I do not think Dr. le Fleming's suggestion goes far enough. I should like to see the old days of apprenticeship revived, though in a modified form. I do not think four years, such as I served, necessary but I do think that before a man is allowed to practice he should be compelled to serve at least *one year's* apprenticeship with a general practitioner. The result would be incalculable benefit to the public and to the man himself.

I would go further and apply the same compulsion to all intending consultants. They would then have a far better understanding of, and a greater sympathy for, the many difficulties with which a general practitioner has to contend.

I am, Sir, yours faithfully,

E. F. PRATT, M.B.

Clarges-street, W., Oct. 10th, 1932.

HOUSE INFECTION IN BLACKWATER FEVER

To the Editor of THE LANCET

SIR,—In a leading article on blackwater fever in your issue of Sept. 17th (p. 636) it is pointed out that Dr. Ross is in agreement with previous observers in finding no justification for the suspicion that certain houses predispose to infection. While on the staff of the C.M.S. Hospital, Ngora, Uganda. I had an opportunity of studying the disease amongst Indians, and would like to draw attention to the following examples which are evidence to the contrary.

(1) On Oct. 30th. 1930, a man. aged 40, developed an attack of blackwater fever after being given plasmoquine and quinine for malaria. His wife had died from the disease in the same house four days previously.

(2) A man. aged 24. came to be examined on April 22nd, 1931, because he was in anxiety lest he might develop blackwater fever, his brother having died from this disease in his house 13 days before. On examination he was found to have a palpable liver, a spleen whose lower limit was three fingers-breadth below the costal margin and a temperature of 101·2° F. His urine had a specific gravity of 1020, was acid in reaction, and contained no albumin or bile. I considered that he was in the pre-blackwater state though it should be acknowledged that certain authorities, including Drs. Ross and Yorke, Murgatroyd, and Owen,[1] do not recognise such a condition.

(3) A man, aged 24. gave a history of seven attacks of blackwater fever, five of which occurred during the year 1930. His daughter, a girl aged 6, who had been living in the same house, also complained of three attacks all of which occurred during the year 1930.

(4) This is an interesting example of a house in which seven attacks of blackwater fever had occurred, two of them being recurrences three years and four years respectively after previous bouts of the disease. Four of the cases occurred during the space of 11 months, between July 6th, 1930, and May 15th, 1931, one of the patients developing the disease one day after his brother. Of the other three cases one was that of a girl who developed the disease two days after her brother. All the patients were members of the same family with the exception of one man who was a cousin. In no case was the disease fatal.

An examination of the house mentioned in (4) shows some features of interest. The building was situated by itself and was enclosed by an orchard of orange and lemon trees which gave shade to the house and protected it against wind. It had a low thatched overhanging roof. The windows were very small and were unprotected by mosquito-netting. The interior of the house was dark even at midday. There were 11 occupants who were subject to frequent attacks of subtertian malaria. Such a building would be an ideal resting place for mosquitoes which could readily gain entrance through the unprotected windows at night, but owing to the absence of light and draught, would show no inclination to leave during the day. This should be compared with the typical house of an ordinary Indian village in this district which, though unprovided with mosquito-netting, possessed a high corrugated iron roof with a wide interval between roof and walls and usually fairly large windows which, if opened during the day, would allow entrance to light and air. There were only a few small trees in the vicinity.

These observations strongly favour the importance of chronic subtertian malaria, which is the prevalent form encountered in this district, in the ætiology of blackwater fever, and the view that certain houses predispose to the disease by reason of the shelter which they offer to the infected anopheles mosquito.—I am, Sir, yours faithfully,

A. D. CHARTERS, M.B. Camb., D.T.M. & H. Eng.

Sevenoaks, Oct. 4th, 1932.

MARMITE IN PERNICIOUS ANÆMIA

To the Editor of THE LANCET

SIR,—In your last issue (p. 782) Dr. A. Goodall records his experience of giving marmite in large doses to 19 cases of pernicious anæmia. Similar findings of my own, as yet unpublished, may be of interest. A year ago I noted in your columns (1931, ii., 63) the occurrence of a reticulocyte response during the administration of bemax, and since that time I have endeavoured to determine the potency of various substances rich in vitamin B for blood regeneration in anæmias. I have found that in Addison's anæmia marmite in doses of 4 oz. daily usually produces a satisfactory reticulocyte response, with a rise of red cells and hæmoglobin, although in some instances the remission has seemed less rapid than with large doses of liver extract. Since these results are obtained in cases of true Addisonian pernicious anæmia with achylia, in which the intrinsic factor of Castle is presumably absent, it would seem possible that yeast contains some substance effective for blood regeneration in this disease, apart from that which Strauss and Castle[1] believe to be the extrinsic factor.

As Dr. Goodall infers in his closing remarks, it would be unwise to let any form of extract take the place of whole liver where subacute combined degeneration of the cord is present.

I am, Sir, yours faithfully,

Newcastle-on-Tyne, Oct. 10th, 1932. C. C. UNGLEY.

TANNIC-ACID THERAPY

To the Editor of THE LANCET

SIR,—My use of tannic acid varies considerably from the ideal set out in your issue of Oct. 8th. In the first place burns of any sort are comparatively seldom the occasion for tannic-acid therapy and, in the second, I have never used it except by direct application of the powder to the surface requiring treatment. I do not for one moment suppose that I am alone amongst general practitioners in using tannic acid in this way nor do I claim any particular skill or priority.

There is a type of lesion with which we are all familiar and which is commonly seen on the faces of motor cyclists who have stopped more suddenly than they intended, usually head first. It occurs also on the elbows of venturesome childhood and even more often on the knees. This lesion is made up of a number of small cuts and scratches set close together. Wet dressings stick to it. Dry dressings do the same. Ointments eventuate in a more or less septic sore calling for fomentations. Long before tannic acid was introduced to the profession as a dressing for burns I had made experiments with various powders in the hope of evolving one which would form an antiseptic scab over such lesions and thus obviate the need for any further dressing. I had very fair success, but the coming of tannic acid was immediately hailed as a possible solution of the problem. Experience has not belied the promise. Thus I found myself embarking on a type of tannic-acid therapy in which solutions and burns had little part. Burns occur from time to time in general practice and, as far as my experience goes, are easily and comfortably treated by dusting the tannic powder directly over the burn. But the main usefulness of tannic acid is in other directions.

The *indications* for tannic-acid therapy are (1) the presence of a raw surface on the epidermis which (2) is little or not at all septic and (3) is likely to cause considerable trouble and pain if treated by any application requiring constant renewal. The surface should not be entirely denuded of epithelium except where the total area is two square inches or less.

The *cases treated* include many injuries occasioned by motor accidents and many examples of the raw area left by avulsion of nails with or without destruction of the nail bed : burns, surgical wounds of which the edges are no longer in apposition, one or two small varicose ulcers, and other similar conditions. A colleague tells me that he has had good results from packing the powder into septic sulci caused by ingrowing toe-nails. In general, sepsis is rather a contra-indication but tannic acid is an excellent antiseptic and can deal with minor septic invasions.

Technique.—Tannic acid will not remove from motor wounds traces of dirt and oil. But it will cover these up and keep them sterile so that they become incorporated in the natural scar forming beneath the tannic-acid covering. The result is not good, especially on the face. Tannic acid will control oozing in most cases but not real hæmorrhage unless pressure also be applied. This involves a dressing in contact with the tannic acid. One tries to avoid such dressings. It is far better that the tannic acid should dry and turn black in contact with the air. When a covering is necessary I use wool applied directly over the acid and bandaged in place. After two or three days I pull or cut away all the wool not involved in the scar, that is, all that will come away. No further dressing or bandage is applied.

Where the area treated is small the thickness of powder applied is not of much moment. It can be powdered on and left for about 60 seconds. The surplus is blown away or lightly brushed away with a piece of wool. Where the area is large, as in an extensive burn, one is left wishing that this powder lent itself better to application with some sort of insufflator. I have thought of mixing it with other powders—e.g., finely powdered aspirin which is soothing—but have not actually done so. The biggest area actually treated in the method outlined above was about a foot square. There were two such areas, one on each thigh, caused by boiling water. The case did very well but the protective covering of tannic acid was not as even as one could have wished. In consequence it cracked here and there, and had to be reinforced during the first two days by further applications of the acid. A solution might have done better in this case, but even application of the powder would, I feel sure, have done better still.

I have never encountered any case in which the application of the tannic acid caused distress, although there have naturally been one or two in whom pain was felt on the first far view of the powder. In no case have I earned anything but the goodwill of hospital sisters and nurses by adopting this treatment.

I am, Sir, yours faithfully,

Sevenoaks, Oct. 9th, 1932. GORDON WARD.

FUSO-SPIROCHÆTAL DISEASE OF THE LUNGS

To the Editor of THE LANCET

SIR,—I have read with interest Dr. Heffernan's note in your issue of Oct. 1st (p. 734) on "fuso spirochætal disease of the lung," of which he describes four cases. May I ask what this disease is ? The note does not make clear whether it is a purulent bronchitis, a lung abscess, or any respiratory infection in which, amongst many others, Vincent's organisms are found. These organisms abound in the sputum of most cases of single lung abscess, from which condition I believ three at least of Dr. Heffernan's patients suffere The first two cases gave a typical history of one typ of lung abscess. An anæsthetic was given for dent extraction ; a few days later there was fever wit symptoms and signs pointing to a lesion in the chest this was followed by the coughing up of a large amour of purulent sputum and rapid cure. The thir case seems to have had a lung abscess which rupture into a bronchus which was inconveniently place for good drainage and so cure was not complet The fourth case was somewhat similar, and I thin the diagnosis of chronic lung abscess, probabl basal, is quite tenable.

I am, Sir, yours faithfully,

London, Oct. 7th, 1932. A. S. HALL.

SAFE MILK

To the Editor of THE LANCET

SIR,—Dr. Carling's letter and the correspondenc on it prompt me to bring to your notice a method home pasteurisation of milk which has been in use my own household for some time. The requirement of adequate pasteurisation are that the *milk shall b* brought to a temperature of 145–150° F. withou any part of it having been heated above this temperature ; *that it shall be maintained at this* temperature for half an hour ; and that it shall then be coole to the lowest practicable temperature.

The first object is attained by heating the milk in a ordinary jug with an electric immersion heater, rated a 400 watts, which raises a quart of milk to the right temperature in 11 minutes. The heater is stirred continuously, an by this means the heat produced is distributed over a larg volume of milk, instead of any portion of the milk bein overheated and coagulated, as occurs in a pan over a ga flame. When the jug feels to be approaching the correc temperature a thermometer is placed in the milk. Th

> rrent is switched off when the temperature reaches 146° F., though the heater is still kept moving until the temperature ases to rise. The rise of temperature after switching off ries with the quantity of milk being heated; with a uart the rise is about 2° F.
>
> The object of the second stage is attained by pouring the eated milk into a warmed vacuum flask (or flasks), which then stood in a warm place for half an hour. During this me the temperature of the milk falls only about 1° F. eantime the jug which is to receive the milk is scalded out ith boiling water, and when the milk from the flask is oured into it the jug is placed in a large dish of cold water.

By these means the requirements of satisfactory asteurisation are fulfilled. There is no doubt s to the milk having been maintained at the required emperature, and its physical properties appear to be n no way altered. The only technical difficulty in he method is the reading of the thermometer. his operation is rather a stumbling block to the ninitiated, and the process of pasteurisation cannot herefore be safely entrusted to the average domestic taff, but must be performed by some member f the household. In view of the advantages of asteurisation, however, the slight trouble involved s well repaid.

I am, Sir, yours faithfully,

F. C. S. BRADBURY,
Assistant Tuberculosis Officer,
Lancashire County Council.

Oct. 8th, 1932.

RESPIRATORY EFFICIENCY TESTS

To the Editor of THE LANCET

SIR,—The letters from Dr. Corner and Dr. Treadgold in your last issue call for some reply. With regard to the criticism that I have misinterpreted Flack, I cannot agree. I have carefully read the Milroy lectures once again and their impression on my mind is this: good air pilots gave certain standards with the mercury U-tube tests, pilots suffering from strain fell below these standards, the general population will probably also fall below these standards because of physical inefficiency, but if only everybody would perform the exercises elaborated in the third lecture, the Air Force standards might be reached. I think this is a fair summary of Flack's views and I believe them to be in this respect unduly optimistic. The only normal standards at present existing for the tests are those adopted by the Air Force and I attempted to show that for the "hospital population" such standards were useless.

Dr. Treadgold suggests that I have misinterpreted the importance attached to the expiratory force and 40 mm. Hg tests by the Royal Air Force authorities, but I tried to make it clear that these were only two out of several tests employed. The phrase I used about the U-tube tests that they were reintroduced by Flack "for use in connexion with standards of respiratory efficiency for air pilots" was meant to convey this, but I ought, perhaps, to have written "other standards." With the rest of Dr. Treadgold's letter I am in agreement.

I regret my slip in attributing the early spirometric work to *Jonathan* Hutchinson when his name was *John*.

I am, Sir, yours faithfully,

London, W., Oct. 8th, 1932. ALAN MONCRIEFF, M.D.

THYROIDEUM B.P. 1932

To the Editor of THE LANCET

SIR,—There is considerable conflict of opinion about the thyroid extract of the new Pharmacopœia. Certain hospitals have been offered U.S.P. Thyroid Powder, which has an iodine content of 0·2 per cent., as being twice the strength of the new B.P. preparation and several inquiries have been sent to us asking if it is satisfactory to dilute this U.S.P. preparation with equal parts of milk sugar to produce the B.P. 1932 product. It should be borne in mind that Thyroideum B.P. 1932, although being standardised to contain 0·1 per cent. iodine in combination as thyroxine, actually contains more than 0·2 per cent. total iodine. An assay of a good grade thyroid will give a content of approaching 0·3 per cent. total iodine. Of this iodine probably 10 per cent. will be inorganic; of the remaining 90 p.c. thyroxine iodine will account for 30 to 60 p.c. The rest of the organic iodine is in the form of acid soluble di-iodotyrosine, which is physiologically inert. Of the three iodines therefore present in thyroid, only one—namely, acid insoluble thyroxine iodine—is recognised in the B.P. 1932 product, and it is on the thyroxine iodine content alone that the standardisation is determined.

We are, Sir, yours faithfully,

ARMOUR AND COMPANY, LTD.
London, Oct. 8th, 1932. (Laboratory Department).

To the Editor of THE LANCET

SIR,—An important point in connexion with Thyroideum B.P. 1932, which is apparently not generally appreciated, is that this thyroid has no fresh gland equivalent. Thyroid of the B.P. 1932 is a dry gland standardised to contain 0·1 per cent. iodine in combination as thyroxine and every batch of thyroid made has to be adjusted to contain this amount. There is thus no standard equivalent of fresh to dry gland and it will therefore be no longer possible to prescribe and dispense thyroid in terms of fresh gland, as is commonly done at the present time.

Further, it should be noted that thyroid extract, thyroid gland, and dry thyroid are now synonyms for thyroid B.P.

I am, Sir, yours faithfully,

H. W. PAINES, M.P.S.
Fitzroy-square, W., Sept. 28th, 1932.

DR. DORIS ODLUM asks us to state that her article on Nomenclature of Mental Disease, in our issue of *Oct. 1st* (p. 754), expresses her own views, and must not be taken to represent the views of the National Council for Mental Hygiene, to which (we stated) she is joint honorary secretary.

A SWEEPSTAKE FOR BRITISH HOSPITALS.—At a special meeting of the council of the British Hospitals Association it has been decided to distribute any money which may be allotted to the Association from a sweepstake held abroad. Sir Harold Pink, the chairman, stated that money so obtained would be used for capital expenditure only. It is understood that a tentative offer has been made by a syndicate to allocate to the hospitals "at least 25 per cent." of the proceeds of a lottery. According to unofficial statements the sweepstakes are to take place under the auspices of the Casino and the International Sporting Club of Monte Carlo. The first sweepstake will be on the Grand National and, to meet the views of the Jockey Club, the draw will not be held until the day of the race.

ROMAN CATHOLIC HOSPITALS.—Dr. Downey, Roman Catholic Archbishop of Liverpool, recently opened extensions to the hospital and nursing home conducted by the Augustinian Sisters at Park House, Waterloo, Liverpool. The enlargements, which have cost £7000, have increased the accommodation for patients from 15 to 32. Eighteen new rooms have been added, including eight private rooms, two maternity wards, a theatre, and a large children's nursery.—A new nurses' home attached to the hospital of St. John and St. Elizabeth, St. John's Wood, was opened recently. The cost has been £18,500, and it will now be possible to house under one roof the staff of 60 nurses who were formerly scattered in three separate houses.

PANEL AND CONTRACT PRACTICE

"Failing to Comply"

THE appeal by the medical officer of a London hospital against a resolution of the London insurance committee, that he had failed to comply with regulations by not personally attending the insured persons for whom he was responsible under contract, was heard on Oct. 7th at the Ministry of Health. The decision of the Ministry is not yet known. In the course of the hearing a rather subtle legal point was raised by the deputy clerk of the committee as to whether there was a difference between "failing to comply" with regulations, and a definite breach of them. He thought there was a difference, but only a very fine one. He suggested that it would have been a breach of the regulations for the doctor in this case to say to his insured patient, who asked for a certificate of incapacity (there being no doubt of the incapacity). "I refuse to give it," but to so arrange matters that he never saw patients at all was failure to comply. The legal assessor thought there was no difference; you could not have a failure to comply without committing a definite breach of the regulations. The case appeared to turn definitely on the fact whether the doctor who did the work —who was undoubtedly non-panel—could be considered as deputy of the insurance practitioner, and as such bound by the regulations.

The Practitioner's Good Name

The Insurance Acts Committee have issued a supplementary report, which will be considered by the Panel Conference when it meets on Oct. 20th. The committee is continually watchful of the interests of the insurance practitioner. It has recently protested to the Ministry of Health at their failure adequately to defend the insurance medical profession when attacked in the House of Commons. A statement has now been obtained from the Minister that the reputation and interests of the insurance panel will on all occasions be appropriately protected and defended to the best of his ability.

Exchange of Views

The Insurance Acts Committee had suggested to the Ministry that before a regional medical officer reports to an approved society that an insured person is fit for light work or other occupation there should be an opportunity of exchange of views between him and the practitioner. The Ministry disagree with this; in this class of case, they say, it is open to the practitioner—

(a) to inform the patient that whereas he had only considered his fitness for his normal occupation he was satisfied on further consideration that he was fit for alternative occupations;

(b) to indicate concurrence with the R.M.O.'s report by issuing a final certificate with a note to the society giving the reasons which led him to modify his previous opinion; or

(c) he may issue an intermediate certificate, intimating his reason for differing from the R.M.O.'s opinion.

In these circumstances the society will frequently refer the case again, and the practitioner is given an opportunity of seeing the case in conjunction with the examining officer at a time fixed to suit the convenience of the practitioner.

Voluntary Contributors in the Post Office

The Postmaster-General has drawn the attention of the British Medical Association to the position of post-office employees entitled by reason of th employment to free medical attendance from post office, and also qualified for medical ben under the N.H.I. Acts by electing to become volunt contributors. Apparently several employees chosen the post-office doctor as their panel doct and this doctor was therefore being paid twice o for the same service. The P.M.G. suggested t this was an infringement of the terms of service the part of the insurance practitioners concern as they had contracted to refrain from accept remuneration from sources other than insurance fu in respect of duties devolving upon them under N.H.I. Acts. He thought that in these cases post-office capitation fee should be scaled down as to exclude duties covered by insurance, 2s. 6d. per head being allowed to cover the advisory and administrative duties which these medical officers would still be called upon to perform. The B.M.A., after consulting counsel, replied that whilst it did not countenance dual payment it strongly challenged the contention that there was any infringement of the terms of service. The P.M.G. then said that whatever the legal position the services rendered under the Act and under the post-office medical service were largely identical, and he suggested a settlement by the end of the year on the lines indicated above. This was agreed to in cases where the post-office doctor and the insurance doctor are the same person. If the voluntary contributor transfers to another insurance practitioner the 2s. 6d. fee reverts to 11s. for the post-office doctor. The private practitioner, who is post-office doctor and not on the list of any insurance committee, is not affected by these proposals.

Brandy as a Medicine

"Doctors may prescribe brandy as a medicine for their panel patients" is reported to be the decision of the Ministry of Health. This settles a dispute that arose in Bath, where an insurance practitioner prescribed "brandy" on a National Health Insurance form, and the prescription was challenged. Apparently the view of the Ministry is that whilst brandy can be used for other purposes that does not prevent its being used as a medicine. Practitioners would, no doubt, be well advised to be cautious in exercising this liberty, as they will have to be prepared to justify its prescribing in the case of inquiry.

The Insurance Acts Committee have approved of the Ministry's proposal that insurance committees should inform insured persons accepting transfer to the successor of a practice, nominated under Clause 4 (1) of the terms of service, that they need not have their cards signed by the successor, the signature of the predecessor being regarded as sufficient.

The new issue of the British Pharmacopœia necessitates a revision of the National Formulary, and suggestions are invited from all panel committees for the improvement of this revised edition. A special committee is working on it, and it is expected to be ready about the middle of 1933.

PAPWORTH VILLAGE SETTLEMENT.—A "dower house" for nurses was opened recently. It has been erected by ex-patients, now employed by Papworth Industries, at a cost of £1750.

OBITUARY

LORENCE ADA STONEY, O.B.E., M.D. Lond., D.M.R.E.

Dr. Florence Stoney, who died on Oct. 8th after long and painful illness, was one of the band of edical women who in August, 1914, within a fortght of the outbreak of war, had already formed emselves into a corps equipped for foreign service, d actually started for Brussels on August 18th. he advance part of the corps, which was organised y Mrs. St. Clair Stobart, were taken prisoners; the ain part escaped, and with its medical staff, organised to release most of the senior women rgeons for other work, set out this time for Antwerp. he quiet skill with which, under Dr. Stoney's direcon, a music hall was converted into a surgical hospital in less than five days won especial praise from the British Consul-General: and though this hospital had to be evacuated in less than a month from its establishment, after being under shell-fire for 18 hours, it filled a need at a time when the British war hospitals had not yet reached Antwerp, for British and Belgian wounded could be taken there straight from the front line. It was this successful enterprise which showed the potentialities of hospitals staffed by medical women, and encouraged Dr. Elsie Inglis later to found the Scottish women's hospitals.

DR. FLORENCE STONEY

[Photograph by J. Russell & Sons

Dr. Stoney was born in 1870, being the second daughter of G. Johnstone Stoney, Sc.D., F.R.S., secretary to the Queen's University of Belfast. She received her medical education at the London (R.F.H.) School of Medicine for Women, where she was a distinguished student. She qualified M.B., B.S. Lond. in 1896, and became M.D. in 1898. After holding an appointment as house surgeon at the Victoria Children's Hospital, Hull, Dr. Stoney turned her attention to the then new specialty of radiology, and organised and developed the X ray departments at the Royal Free and at the Elizabeth Garrett Anderson Hospitals, while acting also as demonstrator in anatomy at the London School of Medicine. This work, combined at first with general practice, and later with private practice as a radiologist, engaged her energies until the war, when it was her desire to put her experience of a specialised branch of medical knowledge at the disposal of the nation, rather than a zest for excitement, that led to her pioneer activities. These did not cease with the evacuation of the Antwerp Hospital. In November, 1914, the corps was abroad again, at the request of the French Croix Rouge, installed in the Chateau Tourlaville, near Cherbourg. It was not suited for a hospital, and Florence Stoney and her colleagues had to arrange for sanitation, water, heating, and even to generate their own electric power. The hospital was soon ready to receive cases; slighter cases were sent on south, and only those very badly wounded were retained. By March, 1915, this stream of wounded had been diverted, and Dr. Stoney felt able to accept the post of radiologist to the Fulham Military Hospital (being for some time the only woman on the staff), where over 15,000 patients went through her department, other hospitals sending in cases for X ray localisation of bullets. Dr. Stoney received the 1914 star, and on demobilisation the O.B.E.

After the war she was unable, on grounds of health, to resume work in London. In 1920 she took the D.M.R.E. at Cambridge and settled in Bournemouth in radiological practice, being appointed consulting medical officer to the electrical department of the Royal Victoria and West Hants Hospital, Bournemouth, and consulting actinotherapist to the Victoria Cripples' Home. She retired in 1928 and travelled in India, studying especially osteomalacia and its treatment by ultra-violet radiation, on which she published observations.

Dr. Stoney's charming whimsical manner made it difficult to perceive at first the strength of her personality. She did not seek adventure, but only the opportunity of quiet service. Her organising skill and tact undoubtedly opened the door through which many medical women subsequently passed without fuss or hindrance to give war service which was recognised as being of the utmost value. It is not generally known that the portable X ray equipment, in those days a rare possession, with which she offered her services in vain to the War Office on August 4th, 1914, was assembled by her and her sister, Edith, as the outcome of Lord Roberts's suggestion that medical women might be of especial use in the event of an outbreak in Ireland. The urge to be equipped for service was a characteristic of Florence Stoney, and enabled her to do well any work which came to her hand.

THE LATE PROF. STIRLING

Dr. REGINALD LAWRENCE (County Hall, Wakefield) writes: "To your obituary notice of Prof. Wm. Stirling I should like to add a personal impression of his lectures which remains vivid after the passage of many years. His tall figure was commanding, and his mannerisms of bearing and dress accentuated the effect. The relation between him and his students was intimate, and his utterance was followed attentively, because without any change in his impassive face he would, with some surprising remark, convulse the class with laughter and as readily check it if it tended to become too boisterous or prolonged. I never knew anyone take liberties with him.

"A more lasting impression, however, is the sloping ledge in front of his lecture table on which were displayed, open at the correct page, the original authorities for the current lecture. He personally stimulated me to learn German, and the occasional loan of the papers and monographs, set out daily, served to keep up the stimulus. But even that was not so powerful as the revelation of his knowledge of physiologists and their milieu which enabled him to write his 'Apostles of Physiology' later. His reference to his 'revered master Karl Ludwig' was always cheered (as a great joke), but the mention of other names, accompanied by contemporary details, was of more than passing interest. Harvey and Malpighi brought with them a short account of the universities of the middle ages, Padua and Bologna respectively; Ranvier as a zoologist showing his genius in the selection of his material to demonstrate histological structures; Claude Bernard working in comparative neglect in a cellar at the Collège de France led on naturally to the University of Paris; and, again, Stannius 'in far-off Rostock' whose ligature of the heart enabled heart muscle t be studied apart from nerve tissue, and described hi discovery in a pamphlet of about two pages (O si si omnes!); Haller, Majendie, Stephen Hales—th neighbour of Gilbert White; and, outside physiolog significantly enough Casanova and Voltaire wl visited England. These are only a miscellaneo few which come to mind, and there were ma others. The allusions were not mere decorati details but part of the texture of his lectures, whi he thus raised to the level of cultural importance."

MEDICAL NEWS

University of London

At recent examinations the following candidates were successful:—

D.P.H.

L. P. Clarke, Dorothy Makepeace, T. L. Narayana, and Doris G. Sharvelle.

University of Liverpool

At recent examinations the following candidates were successful:—

D.P.H.

L. G. Anderson, *F. J. H. Crawford, C. L. Emmerson, H. P. Fowler, and G. A. Fulton.

* With distinction.

University of Bristol

The Long Fox memorial lecture will be given at 5.30 P.M. on Tuesday, Oct. 25th, by Mr. A. J. M. Wright, surgeon to the nose and throat department of Bristol General Hospital. *His subject will be the Problem of Deafness, and the vice*-chancellor of the University will preside.

Medico-Legal Society

At a meeting of this society, to be held at 11, Chandos-street, London, W., at 8.30 P.M. on Thursday, Oct. 27th, Sir John Collie will open a discussion on Fraud in Medico-Legal Practice.

Hampstead and North-West London Hospital

On Wednesday, Oct. 26th, at 3 P.M., Sir Ernest Graham-Little will open a post-graduate course at this hospital with an address on Voluntary Hospitals and their Future. Subsequent lectures will be given on Wednesdays at 4 P.M.

South-West London Post-Graduate Association

A series of lecture-demonstrations will be held at St. James's Hospital, Ouseley-road, Balham, on Wednesdays at 4 P.M. from Oct. 26th. At the first Dr. H. J. Churchill will speak on Anæsthetics in General Practice. Particulars of membership may be had from the hon. secretary, Dr. R. J. Saunders, 10, Lyford-road, Wandsworth Common, S.W. 18.

West Kent Medico-Chirurgical Society

The annual general meeting of this society will be held to-day, Friday, Oct. 14th, at the Miller General Hospital, Greenwich, at 8.45 P.M., when cases will be shown. At the second meeting of the session, on Nov. 11th, Dr. Donald Paterson will speak on Some Advances in Pædiatrics.

London Association of the Medical Women's Federation

The programme for the autumn session opens on Oct. 25th, when a presidential address will be delivered by Prof. Mary Lucas-Keene, entitled Anatomy, Now and Then. On Nov. 22nd Miss M. M. Chadburn, M.D., will read a paper on Mistakes, and on Dec. 15th Mr. A. S. B. Voge, Ph.D., will speak on Recent Research in Contraception. These meetings will be held at 8.30 P.M. at B.M.A. House, Tavistock-square.

British Institute of Radiology

The first meeting of the session will be held in the Reid-Knox memorial hall of this institute, 32, Welbeck-street, London, W., at 8 P.M. on Thursday, Oct. 20th. After the business part of the meeting is over a paper by Prof. Sidney Russ, D.Sc., and Miss G. M. Scott, on the *Differential* Action of Gamma Rays, will be read. On Friday, at 11 A.M., members are invited to visit the radiological department of the City of London *Hospital for Diseases of the* Heart and Lungs, Victoria Park. At 5 P.M. there will be a lantern demonstration on Radiology in Obstetrics by Dr. R. E. Roberts, and Dr. Ulysses Williams will give a brief clinical history of pathological changes recorded in a patient with radium needle in the heart for three years.

Appointments to the Cancer Hospital

It has been decided to increase the medical and surgical staff of the Cancer Hospital (Free), Fulham-road, London, and in our advertisement columns applications are invited for the honorary posts of neurologist, dermatologist, gynæcologist, and ophthalmic surgeon.

Child-Study Society, London

The first meeting of this session will be held at the Royal *Sanitary Institute, 90, Buckingham Palace-road,* S.W., at 6 P.M. on Thursday, Oct. 20th. Mr. P. B. Ballard, D.Litt., will deliver the Cockburn memorial lecture on Thirty Years' Progress in London Education. At the second meeting on Nov. 12th, Miss Anne Adler, J.P., will speak on Children's Courts.

St. Paul's Hospital

A post-graduate course in genito-urinary diseases is being held at *St. Paul's Hospital, Endell-street,* Shaftesbury-avenue, London, W.C., at 4.30 P.M. on Wednesdays until Nov. 30th. This course is free to medical practitioners and students.

National Hospital, Queen-square

Post-graduate courses are now in progress at this hospital They include out-patients' clinics daily (except Saturdays at 2 P.M., lectures and clinical demonstrations on the sam days at 3.30 P.M., pathological demonstrations on Wedne days and Fridays at noon, anatomical demonstrations o Thursdays at noon, and demonstrations of methods o clinical examination on Tuesdays and Thursdays at 5 P.M Further particulars may be had from the dean of the medica. *school, National Hospital,* Queen-square, London, W.C. 1.

Royal Institute of Public Health

A course of lecture-discussions on Mental Defectiveness as a Medico-Sociological Problem will be given at this institute, 23, Queen-square, London, W.C., at 4 P.M. on Thursdays from Oct. 27th. The opening lecture will be by Prof. R. J. A. Berry, chairman of the mental deficiency committee of the British Medical Association, and the other speakers will be *Dr. R. M. Stewart,* Dr. R. G. Gordon, Dr. C. P. Blacker, Dr. Letitia Fairfield, and Dr. Doris Odlum. There will also be a course in preventive medicine at 4 P.M. on Wednesdays from Oct. 19th. It will be opened by Sir Ernest Graham-Little, with an address on Preventive *Medicine and Education of Public Opinion.* Other lecturers will be Dr. D. Chalmers Watson, Mr. Malcolm Donaldson, Dr. H. Crichton-Miller, Prof. W. H. Maxwell Telling, Miss M. F. Forrester-Brown, Dr. C. P. Blacker, and Sir Pendrill Varrier-Jones.

Fellowship of Medicine and Post-Graduate Medical Association

A series of lectures on Renal Disease will take place at the Medical Society of London, at 4 P.M. on Tuesdays. *The* first lecture will be given by Dr. E. C. Warner, on Oct. 18th, on Medical Aspects of Hæmaturia. These lectures are free to members of the Fellowship. A fortnight's course in general medicine and surgery will take place at the Miller General *Hospital, Greenwich, from* Oct. 17th to 29th, occupying the whole of each day. There will be a morning course in diseases of children at the Hospital for Sick Children, Great Ormond-street, from Oct. 24th to Nov. 5th, and a course in neurology, at 5 P.M. daily, from Oct. 31st to Nov. 26th, at the West End *Hospital for* Nervous Diseases. From Oct. 21st to Nov. [illegible] in ophthalmology will be given at [illegible] phthalmic *Hospital.* A weekly [illegible] ctions in Obstetrics and Gynæco [illegible] ry *Abbots* Hospital. A course in [illegible] g *arranged* at the Hospital for [illegible] Further details of these courses may be had from the secretary of the Fellowship, at 1, Wimpole-street, London, W. 1.

Medical Cruise

The weekly review of medicine, *Bruxelles-Médical*, nounces the organisation of a medical cruise for Easter, 33. The itinerary, which commences at Marseilles on ril 8th, closes at the same port on May 1st, and will lude visits to Greece, Corfu, Venice, Sicily, and the riatic coast and the port of Rome. The accommodation reserved for medical practitioners or persons recommended by them, and for practitioners' families, and the lusive charge per head has been fixed at 3975 francs t class and 2100 francs second class. The steamer rtered has 190 first-class berths and 60 berths for dents. Those wishing to join the tour should apply to travel section of the Bruxelles-Médical, 29, Boulevard dolphe Max, Brussels, when further information will be pplied.

ng's College Hospital Dinner

The annual dinner of past and present members of the hool was held on Oct. 1st at the Connaught Rooms. . Godfrey de Bec Turtle presided. The guests of the ening were Mr. A. D. Power, vice-chairman of the committee of management of King's College Hospital, and Dr. D. Cowburn, coroner for South London. The chairman, proposing the toast of the medical school and the hospital, ter paying a tribute to Sir Watson Cheyne as a most stinguished member of the hospital who had died during e year, spoke of recent criticisms of the medical curriculum. Since medicine was a progressive science there uld be no finality about the curriculum, but he held that e end-product obtained—i.e., the newly qualified man or oman—showed that there was nothing radically wrong ith the curriculum. Doctors in this country were very rtunate, for there was practically no unemployment in e profession. After welcoming the guests, Dr. Turtle, behalf of 315 subscribers, presented to Dr. Willoughby yle a piece of hand-wrought plate in commemoration of rvices extending over more than 20 years as dean of the edical school. In thanking the donors, Dr. Willoughby yle gave reminiscences of many King's College Hospital en, notably Sir William Ferguson, Dr. Bentley Todd, Sir illiam Bowman, Lord Lister, Prof. Albert Carless, and r. Raymond Crawfurd, and gave special praise to the ice-deans who had worked under him—Dr. Harold Wiltshire, Dr. J. A. Drake, and Dr. H. A. Lucas. Dr. Drake, he new dean, gave a short account of the work of the edical school during the past year, the outstanding event f which was the beginning of the new buildings, which ill include a new pathological museum, research department, lecture hall, and common rooms. Three members f the school had been awarded travelling fellowships, and nce again a member of the school had also obtained the Murchison scholarship for clinical medicine.

Royal Dental Hospital

At the prize distribution of this hospital on Oct. 3rd, Mr. Harry Stobie, the dean, said that an important change had been made by the Royal College of Surgeons in the regulations governing the licence in dental surgery. Greater emphasis was to be laid on medicine, pathology, and bacteriology, in which there would in future be an examination. He reminded his audience that the new orthodontic department, under the directorship of Sir Norman Bennett, was to be inaugurated that night, and that it was hoped soon to create a special department for the treatment of diseases of the gums. The dean expressed his regret at the resignation of Mr. J. G. Turner, who had joined the staff in 1895, but said that his talents would still be available to the hospital as director of research. Mr. L. E. Claremont had been appointed hon. assistant dental surgeon, and Mr. C. Bowdler Henry and Mr. N. J. Ainsworth honorary dental surgeons. The dean in conclusion referred to the decision to discontinue the admission of women to the school. "It has been decided," he said, "that after March, 1933, no more women are to be admitted as students. Their absence will seem strange, for they have furnished a hard-working and painstaking body of students, and provided the hospital with some of its very best house officers." He also announced that the late Mr. R. Stanway Parris had left a legacy to found a prize to be awarded every year to the student showing the greatest inventive genius.

Lord Riddell, after opening the new orthodontic department and distributing the prizes, gave a short address on How to Teach the Public about their Teeth. He emphasised the necessity of enlisting the aid of the press in arousing interest, but maintained that no serious propaganda effort could succeed unless directed by the expert knowledge of the dentists themselves. At present no provision was made for the dental inspection and treatment of children under 5 and between the ages of 14 and 18. In 1930, of the 2,000,000 school-children who were referred for treatment, only about 1,250,000 actually were treated, and to achieve even this total each dentist had to deal with about 4000 children. To provide a complete school dental service, instead of the present 521 dentists, 2000 whole-time workers would have to be employed. These figures showed that there was little time for preventive work. Under the National Health Insurance scheme some £2,000,000 was at the disposal of the approved societies for dental treatment, but when the number of people to be treated was considered this was not so much as it sounds. Although dental treatment was offered at most antenatal clinics few expectant mothers realised the necessity for availing themselves of it. Lord Riddell said he thought that to remedy these conditions the dentists should form local organisations and strive to create a "tooth sense" among the public, for only then would public opinion demand greater facilities for dental treatment for everybody.

St. Thomas's Hospital Dinner

At Dorchester House, on Oct. 7th, Major-General Sir Guise Guise-Moores said that he was the first Regular Army officer to preside over the St. Thomas's annual dinner. His handling of the situation suggested that the experiment should be frequently repeated, while his anecdotes about the Secretary of State for the Dominions drew out all that was best in subsequent speakers. On turning to more serious subjects, Sir Arthur Stanley, treasurer of the hospital, said that investments worth nearly £50,000 had now been collected towards establishing a really good out-patient department, and that the cost of beer used in the hospital had risen from £30 in 1928 to something like £300 this year. Some of the staff seemed to be prescribing beer instead of drugs, and if this went on St. Thomas's was likely to become increasingly popular. In former days, however, beer had taken an even more prominent place; and here Sir Arthur produced some helpful facts from the first volume of Prof. F. G. Parsons's new "History of St. Thomas's Hospital." In 1584, it appears, the daily allowance of a pottle (four pints) to the hospitaller was raised to a gallon, and so far as he knew this ruling had never been rescinded; though if it were claimed to-day the amount would again be reduced to a pottle, he thought, in the interests of economy. In those days every patient had two pints of beer a day, or three pints in hot weather; and he had calculated that this arrangement would nowadays cost the hospital £12,000 a year. Prof. Parsons's history, continued Sir Arthur, proves that we are much older than Bart.'s. At the time when Rahere came into existence St. Thomas's was being rebuilt after a fire. It was then refounded by Edward VI., with, among others, two sisters to wash the clothes of the poor when necessary and when convenient ("I should think it was always necessary and never convenient") and one expert surgeon to *cure* their diseases ("not what all of you do"). One sober and pious man was also appointed to manage the funds, and Sir Arthur Stanley was delighted to feel that he himself was in the direct succession.

Dr. H. Gardiner-Hill, the sub-dean, reported for the medical school in the absence of Prof. L. S. Dudgeon through illness. After referring to the losses sustained by the retirement of Prof. Hugh MacLean, Mr. H. J. Marriage, and Dr. S. E. Dore, he spoke of the new appointment of Prof. O. L. V. de Wesselow as director of the medical unit, and of Dr. J. St. C. Elkington as assistant physician. Mr. D. F. A. Neilson and Mr. W. A. Mill had been appointed assistant surgeons in the ear, nose, and throat department, and Dr. G. B. Dowling physician in charge of the skin department. Of its old students the hospital had lost, by death, Dr. W. F. Haslam, Mr. Harold Low, Sir Robert Fox-Symons, Mr. J. F. Cunningham, and Dr. E. C. Freeman. During the year Sir Farquhar Buzzard had become physician-in-ordinary, Dr. Maurice Cassidy physician-extraordinary, and Mr. P. H. Mitchiner honorary surgeon, to the King. Sir Percy Sargent had been elected vice-president of the Royal College of Surgeons; Sir Charles Ballance had been awarded the Lister medal of the College; and among the students, Mr. T. A. Lloyd Davies had gained the gold medal in the London M.B. examinations. St. Thomas's had won the inter-hospital boxing for the sixth time in seven years; the sports shield for the third year; all three events of the inter-hospital rowing; and the lawn tennis and golf competitions.

Dr. Gardiner-Hill then proposed the health of the chairman, and he briefly replied.

Charles Mickle Fellowship

The Charles Mickle Fellowship for 1932 has been awarded to Dr. Gaston Leon Ramon, director of the Pasteur Institute Farm at Garches, France, for his work on diphtheria toxin and anatoxin. The fellowship, which is awarded by the council of the Faculty of Medicine of the University of Toronto to the member of the medical profession who in the preceding ten years has done most to advance practical medical knowledge, is the annual income from a legacy of 25,000 dollars left by the late Dr. W. J. Mickle.

University College, Cork

At recent examinations Dr. Denis Hegarty was approved for the diploma in psychological medicine.

Sun Pavilion at Rugby

On Saturday last the Princess Royal opened a new sun pavilion at the hospital of St. Cross, Rugby.

"Alexandra Day" London Collection

It is officially stated that the collections on "Alexandra Day" in London, on June 8th last, amounted to £48,268. To this had to be added collections by steamship companies of £570, and other income, £3566, making a total of £52,404. The expenses amounted to £8327. Of the balance, £5045 was given to charities in which Princess Victoria is especially interested, and £39,461 was distributed to various hospitals and charities.

Elsie Inglis Hospital, Belgrade

The municipality of Belgrade has taken over the Dr. Elsie Inglis Memorial Hospital at Dadinje, near Belgrade, and will run it for ten years. The municipality has also taken over all the debts of the hospital, which was closed down last July. Of the total debts, which are said to amount to approximately £160,000, the municipality is paying £80,000 immediately. The hospital will at once be reopened with 200 beds. It will retain the title of the Elsie Inglis Memorial Hospital, and will still remain nominally the property of the Belgrade Society of Women Doctors, reverting to them at the end of ten years, subject to the repayment of the debts paid by the municipality.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

The following appointments are notified: Surg.-Comdr. L. F. Strugnell to *Vivid*, for R.M. Infirmary, Plymouth.

Surg. Lts. A. Lawrence-Smith to *Pembroke*, for R.M. Infirmary, Chatham; R. Russell to *Codrington*, and A. H. O'Malley to *Vivid*, for R.N.B., Devonport, and for Devonport Dockyard.

ROYAL NAVAL VOLUNTEER RESERVE

Surg. Lt. R. L. Stubbs is promoted to Surg. Lt.-Comdr

ROYAL ARMY MEDICAL CORPS

Maj. F. Worthington to be Lt.-Col.

Maj. J. B. Fotheringham to be Dep. Surg., R. Hosp., Chelsea.

Maj. F. M. Lipscomb, Dep. Surg., R. Hosp., Chelsea, relinquishes his appt.

Capt. G. R. Dobrashian relinquishes his temp. commn.

ARMY RESERVE OF OFFICERS

Lt.-Col. S. E. Lewis, having attained the age limit of liability to recall, ceases to belong to the Reserve of Officers.

TERRITORIAL ARMY

Maj. W. George to be Lt.-Col.

J. V. Bradley (late Cadet Corpl., King Edward's Sch. (Birmingham) Contgt., Jun. Div., O.T.C.) to be Lt.

Supernumerary for Service with the O.T.C.—Lt. A. J. Parer resigns his commn.

INDIAN MEDICAL SERVICE

Lt. (on prob.) J. R. Dogra to be Capt. (prov.) (on prob.)

COLONIAL MEDICAL SERVICE

Dr. E. Cochrane has been appointed Assistant Medical Officer of Health, British Guiana, and Dr. C. Ramdeholl, Medical Officer, British Guiana.

Dr. D. B. D'Alivis, Medical Officer, Grade 1, has been promoted to Inspecting Medical Officer, Ceylon.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED OCT. 1ST, 1932

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 23 (last week 6); scarlet fever, 1792; diphtheria, 840; enteric fever, 68; acute pneumonia (primary or influenzal), 558; puerperal fever, 26; puerperal pyrexia, 71; cerebro-spinal fever, 29; acute poliomyelitis, 32; acute polio-encephalitis, 2; encephalitis lethargica, 12; continued fever, 1 (Doncaster R.D.); dysentery, 9; ophthalmia neonatorum, 74. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on Oct. 4th–5th was as follows:—Small-pox, 42 under treatment, 1 under observation (last week 27 and 2 respectively); scarlet fever, 1472; diphtheria, 1505; enteric fever, 20; measles, 242; whooping-cough, 346; puerperal fever, 24 (plus 8 babies); encephalitis lethargica, 229; poliomyelitis, 6; "other diseases," 160. At St. Margaret's Hospital there were 19 babies (plus 10 mothers) with ophthalmia neonatorum.

Fifteen of the 23 new cases of small-pox were reported from the county of London—namely, Bethnal Green, 3; Hackney, 1; Islington, 3; Poplar, 8.

Deaths.—In 117 great towns, including London, there was no death from small-pox, 3 (1) from enteric fever, 5 (1) from measles, 1 (0) from scarlet fever, 16 (5) from whooping-cough, 22 (7) from diphtheria, *76 (20) from diarrhœa and enteritis under two years*, and 27 (5) from influenza. The figures in parentheses are those for London itself.

The deaths from diarrhœa were maintained, the highest figures being: Liverpool, 9; Birmingham, 7; Leeds, 5. Ealing and Tottenham each reported a death from enteric fever. Diphtheria accounted for 3 deaths each at Leeds and Liverpool, 2 at Manchester. Manchester reported 5 deaths from influenza.

The number of stillbirths notified during the week was 273 (corresponding to a rate of 43 per 1000 total births), including 30 in London.

Medical Diary

SOCIETIES

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, S.W.

TUESDAY, Oct. 18th.—4 P.M., Sir George Newman Harveian Oration.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MONDAY, Oct. 17th.—8.30 P.M., SURGERY: SUBSECTIO[illegible] OF PROCTOLOGY. Paper: Dr. R. C. Coffey (Portlan[illegible] Oregon, U.S.A.): Treatment of Cancer of the Rectum Other speakers: Mr. J. P. Lockhart-Mummery an[illegible] Mr. W. Ernest Miles.

TUESDAY.—5.30 P.M., GENERAL MEETING OF FELLOWS. 8.30 P.M., PATHOLOGY. Presidential address: Prof A. Fleming: Lysozyme.

THURSDAY.—5 [illegible] ses at 4 P.M.) Dr. R. K [illegible] with Hæmochromatosis [illegible] Aldo Castellani 2. Tinea Im [illegible] ropean. Other cases will be shown. 8.30 P.M., NEUROLOGY. Presidential address: Dr. J. S. Risien Russell: Forty Years in Neurology.

FRIDAY.—10 A.M., OTOLOGY. Reception and discussion o[illegible] the Report of the Subcommittee for the consideratio[illegible] of Hearing Tests. 5.30 P.M., PHYSICAL MEDICINE Presidential address: Si [illegible] Stanton Woods 8.15 P.M., OBSTETRICS A[illegible] The Indications for an[illegible] Opener: Dame Louise [illegible] Mr. L. Carnac Rivett, [illegible] Dr. W. S. [illegible] S. G. Luker [illegible] Labour. 7 [illegible] Dr. Russell [illegible] To-day.

EUGENICS SOCIETY.

TUESDAY, Oct. 18th.—5.30 P.M. (at the Rooms of the Linnean Society, Burlington House, Piccadilly, W.) Dame H. Gwynne-Vaughan, D.Sc.: The Contributio[illegible] of Plants to the Study of Heredity.

HUNTERIAN SOCIETY.

MONDAY, Oct. 17th.—8.30 P.M. (at Simpson's Restaurant, Bird-in-Hand-court, 76, Cheapside, E.C.), Dr. Nathan Raw: *Human and Bovine Tuberculosis.* (Presidential address, preceded by dinner at 7.15.)

SOCIETY OF MEDICAL OFFICERS OF HEALTH, 1, Upper Montague-street, W.C.1.

FRIDAY, Oct. 21st.—5 P.M., Dr. G. H. Pearce: The Yorkshire Branch and the Society. (Presidential address.)

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, Oct. 17th, to SATURDAY, Oct. 22nd.—MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W. Tues., Series of Lectures on Renal Diseases. Dr. E. C. Warner: Medical Aspects of Hæmaturia. (Free to Members.)—CHELSEA HOSPITAL FOR WOMEN, Arthur-street, S.W. Course in Gynæcology.—MILLER HOSPITAL, Greenwich, S.E. Course in general medicine and surgery. All day, demonstrations, operations, and lectures. Specially suitable for general practitioners.—St. John's Hospital, Leicester-square, W.C. Clinical instruction daily at 2 and 6 P.M. Lectures on Tues. and Thurs. at 5 P.M.—Central London Throat, Nose, and Ear Hospital, Gray's Inn-road, All day course in Diseases of the Ear, Nose, and Throat.—London Light Clinic, Ranelagh-road, S.W. Lecture demonstrations on Physical Medicine. Mon. and Wed., 8–9 P.M.—The above courses are open only to Members.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 49, Leicester-square, W.C.
Tuesday, Oct. 18th.—5 P.M., Dr. H. T. Barron: Purpura.

ST. PAUL'S HOSPITAL, Endell-street, W.C.
Wednesday, Oct. 19th.—4.30 P.M., Dr. G. R. Mather Cordiner: Radiological Investigation of Urinary Disease.

NATIONAL HOSPITAL, Queen-square, W.C.
Monday, Oct. 17th.—2 P.M., Dr. Riddoch: Out-patient Clinic. 3.30 P.M., Dr. Denny-Brown: Spinal Reflexes.
Tuesday.—2 P.M., Dr. Walshe: Out-patient Clinic. 3.30 P.M., Dr. Denny-Brown: Spinal Reflexes.
Wednesday.—2 P.M., Dr. Martin: Out-patient Clinic. 3.30 P.M., Dr. Collier: Clinical Demonstration.
Thursday.—2 P.M., Dr. Kinnier Wilson: Out-patient Clinic. 3.30 P.M., Dr. Gordon Holmes: Cranial Nerves and Special Senses.
Friday.—2 P.M., Dr. Adie: Out-patient Clinic. 3.30 P.M., Dr. Bernard Hart: Psychoneuroses.

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL, Denmark-hill, S.E.
Thursday, Oct. 20th.—9 P.M., Mr. C. P. G. Wakeley: Head Injuries.

BRITISH INSTITUTE OF RADIOLOGY.
Thursday, Oct. 20th.—8 P.M., Prof. Sidney Russ and Miss G. M. Scott: The Differential Action of Gamma Rays.
Friday.—11 A.M., Visit to the radiological department of the City of London Hospital, Victoria Park, E. 5 P.M. (1) Dr. R. E. Roberts: Radiology in Obstetrics; (2) Dr. Ulysses Williams: Radium Needle in the Heart for Three Years.

ROYAL INSTITUTE OF PUBLIC HEALTH, Queen-square, W.C.
Wednesday, Oct. 19th.—4 P.M., Sir Ernest Graham-Little: Preventive Medicine and the Education of Public Opinion.

NATIONAL COUNCIL FOR MENTAL HYGIENE.
Wednesday, Oct. 19th.—5.30 P.M. (at 11, Chandos-street, W.), Dr. Mary R. Barkas: Guilt.

CHADWICK PUBLIC LECTURES.
Thursday, Oct. 20th.—5.15 P.M. (in the Theatre of the Royal United Services Institution, Whitehall), Sir Humphry Rolleston: The Pioneers and Progress of Preventive Medicine.

MANCHESTER ROYAL INFIRMARY.
Tuesday, Oct. 18th.—4.15 P.M., Prof. E. D. Telford: Osteitis Deformans.
Friday.—4.15 P.M., Dr. A. H. Holmes: Demonstration of Medical Cases.

MANCHESTER HOSPITAL FOR CONSUMPTION AND DISEASES OF THE THROAT AND CHEST, Hardman-street, Deansgate.
Wednesday, Oct. 19th.—4.30 P.M., Dr. Vernon Smith: Nasal Polypi.

ANCOATS HOSPITAL, Manchester.
Thursday, Oct. 20th.—4.15 P.M., Dr. W. J. S. Reid: Anæmias of Chlorotic Type.

Appointments

Ormerod, G. L., M.B., Ch.B. Bristol, has been appointed Medical Officer to the Post Office, Westbury-on-Trym.

Vacancies

For further information refer to the advertisement columns.

Bangor, Carnarvonshire and Anglesey Infirmary.—Jun. H.S. £100.
Barry Urban District Council Surgical Hospital.—H.S. At rate of £200.
Bethlem Royal Hospital, Monk's Orchard, Beckenham, Kent.—Consulting Ophthalmologist.
Bradford Royal Infirmary.—H.P. and H.S. Each at rate of £135.
Beckenham, Bethlem Hospital, Monk's Orchard, Eden Park.—Res. H.P. At rate of £150.
Cancer Hospital, Fulham-road, S.W.—Hon. Neurologist, Hon. Dermatologist, Hon. Gynæcologist, Hon. Ophthalmic Surgeon.
Cheltenham General and Eye Hospitals.—Hon. Surgeon for Ear, Throat, and Nose Diseases.
Chester Royal Infirmary.—H.S. £150.
Eastbourne, Princess Alice Memorial Hospital.—H.S. At rate of £150.
Fareham, Hants, Knowle Mental Hospital.—Third Asst. M.O. £350.
Gloucester County and City Mental Hospital.—Jun. Asst. M.O. £350.
Gloucester, Gloucestershire Royal Infirmary, &c.—Hon. Anæsthetist.
Great Yarmouth General Hospital.—H.S. £140.
Hertford County Hospital.—Hon. Ophth. Surgeon.
Kidderminster and District General Hospital.—H.S. £150.
Lancaster Royal Infirmary.—Jun. H.S. At rate of £130.
Liverpool, County Mental Hospital, Rainhill.—Asst. M.O. £500.
Liverpool Hahnemann Hospital, Hope-street.—Res. M.O. At rate of £100.
Liverpool Royal Babies Hospital.—Res. M.O. At rate of £90.
Liverpool University.—Junior Lecturer for Dept. of Pathology. £300.
London County Council.—Asst. M.O. £475.
Manchester City Education Committee.—Asst. School M.O. £600.
Manchester Royal Children's Hospital, Pendlebury.—Res. Surg. O. At rate of £125.
Middlesex County Council.—Asst. County M.O.H. £750.
Minehead and West Somerset Hospital.—Res. M.O. At rate of £150.
Nottingham, Harlow Wood Orthopædic Hospital.—Asst. to the Surgeon in Charge. £450.
Plymouth, South Devon and East Cornwall Hospital.—Res. Surg. O. and H.S. to Special Departments. At rate of £150 and £100 respectively.
Princess Louise Kensington Hospital for Children, St. Quintin-avenue, N. Kensington, W.—Hon. Asst. Surgeon to Nose, Throat and Ear Dept.
Putney Hospital, Putney Common, S.W.—Hon. Consultant Ophth. Surgeon and Oto-Laryngologist.
Queen Charlotte's Maternity Hospital, Marylebone-road, N.W.—Obstetric Surgeon to Out-patients.
Reading, Royal Berkshire Hospital.—Res. Anæsthetist. £150.
Rochester, St. Bartholomew's Hospital.—H.S. At rate of £175.
Royal Eye Hospital, St. George's-circus, Southwark, S.E.—Hon. Asst. Surg.
Royal Free Hospital and London (R.F.H.) School of Medicine for Women, W.C.—Sen. Assist. At rate of £250. Also Second and Third Asst. £300 and £270 respectively.
Royal National Orthopædic Hospital, 234, Gt. Portland-street, W. Two Registrars. Each £105.
Royal Waterloo Hospital for Children and Women, Waterloo-road, S.E.—Cas. O. and H.P. £200 and £100 respectively.
St. Bartholomew's Hospital, London, E.C.—Asst. Phys.
St. Mary's Hospital, W.—Med. Supt. £400.
St. Mary's Hospital, Institute of Pathology and Research, Paddington.—Research Studentship at rate of £200.
St. Olave's Hospital, Lower-road, Rotherhithe, S.E.—H.P. At rate of £80.
Samaritan Free Hospital for Women, Marylebone-road, N.W.—H.S. At rate of £100. Also Anæsthetist.
South Shields, Harton Hospital.—H.S. At rate of £150.
The Radium Institute, Ridinghouse-street, W.—H.S. At rate of £150.
Uxbridge, Hillingdon County Hospital.—Chief Asst. Radiographer. £225.
Victoria Hospital for Children, Tite-street, Chelsea, S.W.—Anæsthetist. Also Sen. Res. M.O. £200.
Whipps Cross Hospital, Whipps Cross-road, Leytonstone, E.—Med. Supt. £1100.
Willesden, Municipal Hospital, Brentfield-road, Neasden, N.W.—Res. M.O. £250.

The Chief Inspector of Factories announces vacant appointments for Certifying Factory Surgeons at Chesterfield (Derby); Clay Cross (Derby); and Wolverhampton (Staffs).

A vacancy is announced for a Medical Referee under the Workmen's Compensation Acts (Northern Ireland) for the County of Fermanagh. Further information may be obtained from the Secretary, Ministry of Labour, Stormont, Belfast. Applications must be forwarded not later than Oct. 22nd.

Births, Marriages, and Deaths

MARRIAGES

Lachlan—Mansel.—On Oct. 8th, at Holy Trinity, Brompton, Kenneth Harry Lachlan, M.B., of Brentwood, to Lola, only daughter of the late Charles Mansel, O.B.E., M.D., and of Mrs. Mansel, Whitelyons, Brentwood, Essex.

DEATHS

Brown.—On Oct. 3rd, at Kennington Park-road, Thomas Brown, M.R.C.S., in his 80th year.

Carroll.—On Oct. 5th, at Harrington-gardens, S.W., of pneumonia, Colonel Frederick Fitzgerald Carroll, D.S.O., R.A.M.C., late of Egyptian Army and late of Moore Abbey Co. Kildare.

O'Connor.—On Oct. 7th, at Southsea, after a long and trying illness, Bernard O'Connor, M.D., D.P.H., M.R.C.P. Lond., and Barrister-at-Law, in his 84th year.

Stoney.—On Oct. 7th, Florence Ada Stoney, O.B.E., M.D. B.S. Lond., D.M.R.E. Camb., in her 63rd year.

Thorne.—On Oct. 6th, at The Mynde, Caerleon (Mon.), Atwood Thorne, F.S.A., M.B. Lond., aged 65.

Thorne.—On Oct. 4th, John Mills Thorne, M.R.C.S., L.R.C.P., of Brockham Green, Surrey, aged 70.

Tosswill.—On Oct. 3rd, at Queen Mary's Hospital, Roehampton, Major Leonard Robert Tosswill, O.B.E. Mil., M.R.C.S., L.R.C.P., D.P.H., of Mistletoe Farm, Cuckoo-hill, Eastcote, aged 52 years.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

NOTES, COMMENTS, AND ABSTRACTS

DIABETES IN SCANDINAVIA

SICKNESS insurance on the one hand and insulin on the other, have profoundly changed the administrative problems of diabetes since the beginning of this century. A third factor, which some think contributes greatly to the seriousness of diabetes as a cause of disablement and death, is the big jump in the consumption of sugar per head in many civilised countries in our own times. The interplay of these and other factors as they affect the four Scandinavian countries, Denmark, Norway, Sweden, and Finland, is discussed in as many papers by their respective nationals, in *Nordisk Medicinsk Tidskrift* for Sept. 3rd. In Finland, it is stated, the consumption of sugar per head rose from 15·9 kg. in 1913, to 27·4 kg. in 1929. (In this year the consumption of sugar per head in the United States of America is said to have been 50·3 kg.) In 1890 only 10 diabetics received treatment in the hospitals of Copenhagen; at the present time there are between 5000 and 6000 diabetics in Denmark, and the central organisation for sickness insurance has an elaborate machinery for dealing with the insured diabetic worker. This organisation puts the services of its specialists at the disposal of general practitioners and does much else so that each case may enjoy the benefits of up-to-date knowledge adapted to individual needs. Before the introduction of insulin 89 per cent. of the insured diabetics applying for sickness benefit were treated as permanent invalids with a working capacity below a third of the normal. Thanks to the administrative machinery now at work, and the benefits of insulin which it is able to provide, only 38 per cent. of the persons applying for sickness benefit in 1930 had to be classed as permanent invalids.

The problem of the diabetic child in Norway is dealt with by Dr. Kirsten Toverud, who points out that insulin has produced an entirely new problem as far as the diabetic child is concerned. Formerly he just died, after an illness whose average duration was only 2·6 years according to Joslin. Now, with every year, there is a new crop of diabetic children capable of reaching healthy adult life if properly cared for. Even in such a small country as Norway the ranks of the diabetic child are being recruited by between 200 and 300 newcomers every nine years. Hitherto they have fared badly, about half of them dying for want of systematic supervision. Hence Dr. Toverud's advocacy of a combined diabetic home and dispensary where in-patient treatment can be supplemented by educational facilities so that the first period of hospital treatment does not entail too great a break in the child's life. Such a home, staffed by a specialist and a nurse, should also serve as a dispensary to which the child could come for periodic supervision.

The extent to which the diabetic problem in Sweden has grown from the administrative point of view, is shown by Dr. G. Kahlmeter, who states that while in 1918 only 30 insured persons received sickness benefit for diabetes, their number had risen to 246 in 1928. As for Finland, a paper by Dr. Holsti, shows that in Helsingfors the diabetes mortality for 1926–30 was higher than for any other quinquennium in the last twenty years. Yet it was only during these last five years that insulin had been extensively employed.

A NEW HEARING AID

IT is well known that the hearing of a deaf person may not be equally diminished through the entire range of audible frequencies; the subject of chronic middle-ear deafness, and especially of otosclerosis, is usually particularly deaf to the lower notes of the scale, while hearing high tones relatively well, whereas the sufferer from nerve-deafness fails to hear sounds of high frequency, such as the squeak of a bat or the song of birds. In a smaller number of cases, the hearing for different frequencies is much more irregular, and islands of hearing, or of deafness, may be found in various parts of the scale. With the ordinary micro-telephone type of electrical hearing aid, it is possible to amplify more especially the upper or the lower end of the scale, and this is sometimes done; but the instruments usually sold with a more or less "straight line" amplification have the defect that they magnify tones to which such a patient is not deaf, and may thus cause discomfort and even pain. If, however, the construction used in wireless receivers is followed, and valve amplification employed, it is possible to introduce filter circuits to give any characteristic desired. One difficulty in the practical use of such an apparatus has been that a current of at least 80 volts tension is necessary for the ordinary wireless valve, which involves the use of a prohibitively large and heavy battery; but the invention of the double-grid valve working at 25 volts has allowed an instrument to be put on the market of the size of a small box-camera, and weighing about four pounds. This has been produced by Messrs. Radio-Aid, Ltd., 4, Iddesleigh House, Caxton-street, London, S.W. 1, who are prepared to carry out the necessary tests before supplying the instrument, and who hope to develop an organisation by which patients living in the country, as well as those who live in London, can be tested. If such an instrument is carefully adapted to each individual patient after proper tests, it may prove to be of real service to those deaf people whose hearing varies much for different tones, and who are therefore unable to obtain help from the usual type of aid. Sufferers from senile deafness are not likely to obtain benefit from this instrument; and of others, only those whose deafness is severe are likely to avai themselves of it, for it is still a somewhat bulky piece of apparatus. The Radio-Aid Company have also designed a simplified form of audiometer, with which to make the necessary tests; it is named the audiograph, and is smaller and less expensive than the audiometers previously obtainable. Frequencies from 125 to 4000 cycles can be tested, and the volumes can be varied over 20 units of sound intensity. This instrument may commend itself to otologists for use in consulting rooms.

NEW PREPARATIONS

RADIOSTOL SOLUTION AND PELLETS.—These preparations of irradiated ergosterol, from the laboratories of British Drug Houses, Ltd., Graham-street, City-road, London, N., provide a pure crystalline vitamin D in two forms. The solution has a vitamin D activity such that one fluid ounce of the solution is equivalent in that respect to 2½ pints of cod-liver oil. The pellets contain the vitamin incorporated in cocoa butter, and one pellet is stated to have a vitamin content equivalent to that in an adult dose of cod-liver oil, and it is recommended that one should be eaten after a meal once or twice a day. The dose of the solution, prophylactic or therapeutic in intention, ranges from 5 drops daily to 10 drops three times daily.

(1) TAB. SODA RHEI CO.: (2) TAB. CEREVISIÆ CO. (Messrs. Barnold, Ltd., Milverton-street, Kennington, London). (1) This preparation in tablet form is a compound of bicarbonate of soda, carbonate of ammonia, rhubarb powder and peppermint oil, and the suggested dose is two or three tablets after meals. The assistance that would be rendered in certain forms of dyspepsia is obvious from the composition, and the tablets are a convenient form of administration. The advice that they should be given under medical direction is printed on the label. (2) This preparation is a compound of yeast and glycerophosphates, and attention has already been drawn to it in these columns (THE LANCET, Feb. 11th, 1928). Experimentation on mice and rats supports the manufacturers' opinion that in conditions of wasting or under-nourishment the tablets would be valuable. and they have received evidence suggesting that steady growth in the human subject has accompanied the use of the tablets.

ADDRESSES AND ORIGINAL ARTICLES

HE DEBT OF PREVENTIVE MEDICINE TO HARVEY AND THE COLLEGE OF PHYSICIANS*

By Sir George Newman, K.C.B., M.D. Edin.
F.R.C.P. Lond.
CHIEF MEDICAL OFFICER OF THE MINISTRY OF HEALTH

The facts of Harvey's life have often been recited ithin these walls and are well known to you. His me rests upon two achievements. He rendered the ollege of Physicians manifold services for half a ntury, and left it precious legacies and benefits. nd by his discovery of the circulation of the blood, hich Sir Thomas Browne preferred to the discovery f America, he became the founder of modern hysiology. He it was who opened wide for the science f medicine the gates of the Renaissance and revealed, ke Copernicus, a new orientation of human thought. he discovery itself was two-fold, that the blood hroughout the living body circulated from the heart hrough the arteries and back to the heart again hrough the veins, and that this movement was ropelled by the contraction of the heart. The stablishment of these two simple facts ended notions, heories, and doctrines which had endured for 1500 ears.

Galen and Harvey

Claudius Galen of Pergamum (A.D. 130–201), the reatest physician and the only experimental physio-ogist of the Roman world, and medical attendant f the emperor, Marcus Aurelius, had left stereotyped n his authoritative writings, the current views of the blood system. He demonstrated that the arteries contained blood and not air, he held that there were in the blood two tides, a general one and a pulmonary one, or rather that the body was irrigated by two kinds of blood serving a double purpose, one in the veins and one in the arteries. Both contained spirits, a "natural spirit" derived from the liver, an "animal spirit" from the brain, and a pneuma or "vital spirit" from the lungs, though the spirits in the two bloods were not identical. Galen declared also that there was communication through the apparently solid septum between the right and left ventricles, so that there was a partial percolation of the blood between the ventricles. He also claimed that the heart was a bellows, a suction and mixing tank in which the blood was both collected and heated, that the liver was the source and centre of the blood stream, that the veins had *no* valves, and that the blood system included pulmonary circulation. Now, with the exception of the teaching on the valves in the veins, this was the generally accepted belief before Harvey's time. It was not merely incorrect, but it stood in the way of any sound conceptions of physiology as a whole. Harvey's observations and experiments led him, first, definitely to exclude belief in various "spirits" in the blood, of which there was no evidence; secondly, he found no perforation of the interventricular septum and therefore no passage of blood could take place through it; thirdly, he had learned from Fabricius that the veins had valves, but he observed that they were so placed as to assist the blood in its return to the heart; fourthly, following Aristotle, he found the heart was a muscular pump propelling the blood to the tissues, the right ventricle to the lung and the left ventricle to the rest of the body, "and this is the sole and only end of the motion and contraction of the heart;" and lastly, he demonstrated that the whole mass of blood passed rapidly through the heart, the lungs, and the whole body. This was Harvey's demonstration of the mechanism of the circulation of the blood—pregnant with vast consequences, loaded with fate, something more than an interpretation of the special function of the heart and blood-vessels, more than the explanation of a mechanical act. For, in the first place, he arrived at his conclusion not from books nor logical deduction from facts, but by direct observation and experiment. In his little book, one of the most wonderful little books in the history of man, he sets out, step by step, the mechanical course of events in the cardiac cycle, illustrated by his own convincing tests and experiments. Thus he applied the scientific methods of Aristotle and Roger Bacon as the means of discovering the secrets of Nature. As a Vesalian anatomist he studied the anatomical morphology of the blood system in both man and animals; as a Galenic disciple he conceived of the function of the structures he found, and devised experiments, by vivisection or otherwise, for proving the validity of his interpretations; and he was one of the first to use physical measurement in biological inquiry. And, in the second place, he was never in any doubt that an understanding of the circulation provided the only basis for the intelligent study of the function of the blood itself and of the physical nature of man, of which he claimed the heart as sovereign. So long as the blood contained demons and spirits, was dual in character, and was static or tidal, and so long as the heart was a mixing tank and heat generator rather than the propeller of a circulating fluid, there could be no new physiology. Thus, whilst he neither foresaw nor formulated the subsequent research in physiological problems, he led men to expect an abundant harvest from his seed-sowing. How abundant and how varied will become evident to the reader between the lines of his famous book—see, for example, chapters VIII., IX., and XVI.

Harvey was heavily handicapped by ancient tradition. As Sir Michael Foster said, while Harvey was destroying Galen's doctrines he was wearing Galen's clothes and speaking with Galen's voice. He was also restricted by current knowledge, and could not, for lack of data, explain the ultimate intention of the design which he revealed, a restriction which still governs all scientific deduction. Nor could he complete his work, any more than any other explorer, for it was not a summary of existing knowledge from previous records, but an experimental stage in the development of a high argument. Harvey was a naturalist, like Newton or Darwin; his guiding star was Aristotle and his problem was to discover the nature of man by elucidating the properties and functions of the organs and tissues of the body; and, like all other discoverers, he entered into other men's labours, as his followers entered into his own.

The New Physiology: its Promise for Prevention

Here, therefore, was the opening of a new epoch. In 1622, six years after Harvey's first Lumleian discourse, and six before his book was published, came the demonstration of the lacteals and lymphatic system by which nutriment reached the blood (Aselli, Pecquet, and Rudbeck), an advance strangely criticised, and even unaccepted, by Harvey. In 1648 began the exploration of the chemistry of digestion and the blood (Van Helmont). Ten years later, and one year after Harvey's death, there came (with the microscope) the discovery of the corpuscles of the blood (Swammerdam, Malpighi), and with them the tremendous fact of its nutritive power, and shortly after, in 1661, Malpighi similarly revealed the fine capillaries in the tissues, believed in by Leonardo da Vinci and Harvey himself, but in the absence of the microscope not seen by them. All the deeper problems of physiology, as we now know, turn on the nourishment of the tissues themselves; the blood feeds them and acts on them, and they react on the blood. In 1662 came the first fruits of the mechanics of physiology (Descartes, Borelli), two generations after Galileo's initiation at Pisa and Padua; in 1669 new light was thrown, and thrown forward for a hundred years, on the physiology of respiration, on the purpose and process of the aeration of the blood in the lung, on its selective use of the oxygen of the air, on its carriage to the tissues by the blood, and on the resultant vitality and functioning of those tissues. The work of that bright school of young English physiologists, Boyle, Hooke, Mayow, and Richard Lower our own Fellow, worthy children of the great Harvey, was to be followed in the succeeding century by the actual separation of the gases which control life, carbonic acid, nitrogen, oxygen, and hydrogen. In the eighteenth century also there came the beginnings of the new knowledge of the nervous system and of digestion. In the middle of the nineteenth century Berthold opened a vast new field of research into the secretions of the ductless glands, and later Bernard, Addison, and Brown-Séquard established the foundations of endocrinology. The progress of physiology in England in recent times has been pre-eminent in quantity, quality, and scope, even in a time of universal scientific advancement.

---

* The Harveian Oration delivered before the Royal College of Physicians of London on Oct. 18th.

From these illustrations of the kind of discovery that was going forward, I turn to mention some of their applications in preventive medicine. The organised attempt to prevent disease began in England in the fourteenth century when the nation was faced with the disaster of the Black Death, which reduced the population from four millions to two millions in a single year. From that dark day to the present there has been steady, and in recent years, rapid advance. From the sixteenth century the State itself took a hand in the business, and in our own time has secured the coöperation of the private practitioner, the research investigator, and the public medical officer. Their joint achievements have distinguished the last hundred years beyond other secular periods. I suppose that in no previous epoch in the history of mankind has there been such growth of the conception of preventive medicine and the practice of its art. It has saved millions of lives from premature death or crippling disease; it has extended the expectation of life for every infant born; it has, in Rudyard Kipling's phrase, "smote for us a pathway to the ends of all the earth," peopling whole tracts of the world which have formerly been decimated or deserted. In doing these things it has become a primary factor in the destiny of nations and in the future of man's life. It is difficult to make a selection of illustrations, from what Dryden would have called "God's plenty," to prove this growth of knowledge *or its applications*, because of their manifold an varied character. But I will offer for your consider tion three examples, and each of them shall be descendant of the achievement of the immort Harvey.

(1) THE PHYSIOLOGICAL BALANCE AS CONSERVATI OF HEALTH

Claude Bernard devoted his life to physiologi research in Paris and obtained a world-wide reput tion for four discoveries between 1843 and 1853 namely, the glycogenic function of the liver, t action upon digestion of the pancreatic juice, t nerve control of the walls of the arteries, and t displacement of the oxygen in the blood corpus in carbon monoxide poisoning. He died among vineyards in 1878. No one can consider the formi able and varied advances of modern physiolo without wondering whether it is possible to wea them into a synthetic "grand purpose," as Bor *foresaw it. Apart from his specific discoveries* t is what Bernard did, and it was perhaps his great service to physiology. "Animals have really t environments," he said, "an external environm in which the organism is situated, and an inter environment in which the tissue elements live. . *All the vital mechanisms of the body, varied as th* are, have only one object, that of preserving consta the conditions of life in the internal environment."

This is the synthetic principle of Bernard, that the vital functions of the body establish jointly constant and stable internal environment for organism which lives its life amid a variable exter environment. He was led to his conclusion by constancy of the proportion of sugar in the bl as regulated by the liver, but in the last half centu we have learned of the relative constancy of alkalinity and content of the blood (even in tra fusion), of the process of respiration, of bo temperature, of the nervous integration and regulat of the body, and of the control of the body by circulation in the blood of the endocrine secretio Wherever we turn we find evidences of this inter constancy, maintained by respiration, circulati the course of digestion and nutrition, the activit of the liver and kidney, the secretions of the ductl glands, and the total metabolism of the normal bo We must be reserved in attempting to assess findings of physiology, to say what is great and wl is small, but we shall be safe in accepting provisiona this supreme synthetic interpretation as among highest gifts.

The further Claude Bernard reflected upon deduction the more convinced he became both of validity and its practical application. He says 1865: "Physiologists and physicians gain maste over the phenomena of life by learning which con tions in the inner environment are normal and whi are abnormal. . . . It is in the study of these inn organic conditions that direct and true explanatio are to be found for the phenomena of the life, healt sickness, and death of the organism." He saw inde in his day that health and capacity depend upon th physiological balance of the constant internal enviro ment surviving and moving in a variable extern environment. He wanted men to understand it, regard it, and to live by it. We now see in our da that the mastery is being attained, in rationale and practice. In a word, we are beginning to apprehen the physiological life as the basis of health and as th foundation of preventive medicine. Claude Bernar like Harvey and Hippocrates *before* him, saw tha he physiological life, Nature herself, is the healer f disease and the protection against its invasion.

This conception was first put into practice in the fth century B.C. in the Aesculapian temples, the natoria of the ancient world; it was carried forward y the gymnastics of the Greeks, by the hygienic ision and education of Hellenism, by the substitution f natural ætiology for the supernatural dæmonic nagic and medicine of the East; it inspired the nitation of the Roman Empire, and there, and in he writings of Celsus, Pliny, and Cicero, it lay mbalmed for centuries. The conservation of health n physiological balance revived in the Renaissance nd was carried from Florence to Padua, and thus to Leyden and England. We may find it in the letters of Erasmus, in More's "Utopia," in Linacre's translaion of Galen's "Preservation of Health," scattered hrough Shakespeare's plays, in the writings of Sir Thomas Browne and Lord Bacon, in Sydenham's etters, in the great work on Hygiene of Peter Frank he Bavarian—everywhere for the rich and scholarly. Yet it still had to be given to the great mass of the people.

Its proof was sealed by Bachstrom, Lind, and Sir Gilbert Blane in their defence of the health and dietary of seamen; by William Cadogan of this College, who learned it in Leyden and was the first of our Fellows to apply it to mothers and children; by Sir John Pringle, who also found it in Boerhaave's classroom and decided to devote his life to its science, with the result that he reformed the health of the army, and laid a foundation of personal and public hygiene broader and deeper than any previous Fellow of the College. In our own day we have been the witnesses of the labours of a group of physiologists, some of them Fellows of the College, who have abundantly proved the validity of the constant internal environment by the new light which they have thrown upon the internal secretions, chemical and nervous regulation, and the nutrition of the body of man. They established not only our knowledge as to the basis of the conservation of health, but also the application of that knowledge to the direct prevention of disease. We now know that physical health and mental capacity depend upon a mutual contribution of nutrition, hormones, nervous regulation, and oxygenation of the circulating blood, as we also know how these factors can be made direct instruments of the prevention of disease, and thus fulfil the office of medicine, "to tune this curious harp of man's body and reduce it to harmony."

(2) THE CAUSE AND CONTROL OF INFECTIVE DISEASE

Harvey held that the circulating blood carried infection. No group of men followed more faithfully the teaching of Harvey and Sydenham than the physicians of the eighteenth century. By that time the circulation of the blood was fully accepted, and Harvey's mode of workmanship had become part of English tradition, and particularly the standard of this College. Glisson, Regius professor of physic at Cambridge when Harvey was travelling in Europe, was incited by Harvey's example in thorough investigation, and his work on rickets brought together for the first time in England the anatomical and clinical characters of a disease. One of his contemporaries, who also became President of the College, was Sir Edward Greaves, who published in 1643 the first English description of epidemic typhus fever as he saw it in the King's Army at Oxford. Sydenham attempted to arrive at general laws as to the prevalence and course of epidemic disease. Here are three types of investigator who set agoing the annalists of the eighteenth century; they explored the circumstances and clinical features of infective disease, and observed their relation to external environment, to seasons, and to meteorological conditions. Further, Huxham investigated typhoid, typhus, Devonshire colic, scurvy, and diphtheria; Heberden, chicken-pox, measles, epidemic colds, and diphtheria; Fothergill, epidemic sore-throat; Haygarth, small-pox and typhus; Pringle, gaol fever, dysentery, and influenza; Sir George Baker, Devonshire colic and scurvy; Edward Jenner, small-pox and cow-pox; and Willan, skin diseases in London. The seventeenth and eighteenth centuries were, as Charles Creighton demonstrated to us, a new era of epidemics, which became more obvious after the disappearance of the plague. Much was conceived tentatively by way of prevention, and there was a remarkable output of clinical observation, as necessary to-day as then, particularly in differential diagnosis, the effects of treatment, and prognosis. What was lacking was any exact knowledge of causation. In spite of that, the practical sense of the English did, in fact, achieve before the end of the eighteenth century, two significant conquests in this long list of diseases—namely, the control of scurvy and of small-pox.

The mighty movement which changed the whole situation was the advance of bacteriology. It began with surmises and conjectures in the sixteenth century. Fracastor in 1546; Borelli a hundred years later; in 1676 Leeuwenhoek, of Delft, who saw living bacteria by the use of a lens made by himself, provided surmises and conjectures, but it was a long time before the relationship of these living "animalcula" came to be associated with disease. In 1835 Agostino Bassi found the muscardine of silk-worms to be caused by germs, and so became the founder of the germ theory; Pasteur, by his study of fermentation and viruses, and Koch by his ingenious technical methods of isolation proved the case. Only as we view at a distance their labours in the last half of the nineteenth century are we able to appreciate the revolution in the science and art of medicine which they achieved. If we reflect on the fact that in the brief period of 15 years (from 1880–1895) there was discovered the bacterial cause of nine diseases: typhoid fever, tuberculosis, suppuration, glanders, cholera, diphtheria, tetanus, Malta fever, and plague; and that in the same period there was provided the initial form of protective inoculation against anthrax, rabies, diphtheria, tetanus, cholera, and typhoid, we shall understand the magnitude of the modern conquests of preventive medicine.

Much had to be done, much still remains to be perfected, but here we are in an altogether new kingdom, the control by the body of infective processes. But the discovery of the cause of disease lies at present largely beyond statistical calculation, for which indeed the data are often unavailable. It is a story of laboratory exploration, but it exerted an effect outside the laboratory. For the discovery of causal pathogenic organisms immediately led to finding them in the tissues of the affected person. In typhoid, tuberculosis of the lung, diphtheria, tetanus, and plague there arose forthwith the need for a bacteriological diagnosis as well as a clinical. The physician called in the bacteriologist, and the relation of bacteriology to clinical diagnosis became a subject of lively discussion. It stimulated inquiry into possibilities of destroying the bacilli before they entered the body, into the channels of infection and their control, into inoculation and vaccination, and into antitoxin treatment. Lister's application of antiseptic principles exerted no doubt a highly beneficial effect upon surgery, but its influence was much wider, for it demonstrated a means of control of almost universal application.

Only a generation has passed since the bacterial cause of disease has been our possession. Yet there has been time to assimilate the new knowledge and correlate it with the old, to recognise that in the production and determination of disease the *seed is one factor and the soil another.* The study of the interaction between them has been illuminating and profoundly instructive. It has confirmed and even fortified the Hippocratic and Harveian confidence in the nature of man's body. Though we cannot as yet assess the degree of control with which this new knowledge empowers mankind, we are not without encouragement provided by a decline in the incidence and mortality of disease, proof of which is supplied by the latest returns of the Registrar-General, though we must beware of *deducing from these returns that certain remarkable* declines in annual mortality are wholly the result of human action.

(3) IMMUNITY

A third example is artificial immunity, an acquired defence of the host against harmful influences of bacterial origin, perhaps the greatest single advance in modern preventive medicine. It was known before Sydenham's day that an attack of measles or small-pox naturally protected the patient from further attack, and Harvey knew that the blood had protective qualities. But it is only in our own times that explanation of this property has been attempted and found. Pasteur used to say that he received part of his inspiration from Jenner and his empirical experiments in vaccination. Pasteur's chicken-cholera vaccine was in fact comparable to variolation, the inoculation of an attenuated variola. This was the first step in the new movement. In 1880–81 Lister demonstrated the bactericidal property of ox-blood. He showed that it had no inherent tendency to "putrefaction," and that, different from milk, it could indeed withstand "seeding" with tap water and even dust, without apparent decomposition. "These two great truths," he declared, "have been taught us by advancing science: that normal serum is not a good soil for the development of attenuated microbes, and that bacteria introduced among the tissues, if in not too concentrated a form, are disposed of by phagocytosis." Metchnikoff had already described the phagocyte.

Here we have the four facts which formed the basis of the organised exploration which began in our own time—the natural protection provided by an attack of measles or small-pox, the attenuated virus of Jenner and Pasteur, the bactericidal defences of the blood itself, and the phagocytosis of Metchnikoff. Recent study has shown that phagocytosis is more of a physico-chemical effect of various polynuclear cells than, as Metchnikoff assumed, a specific "voracious" faculty of certain particular leucocytes only. It has also shown that the bactericidal property of the circulating blood finds expression in antibodies and opsonins of various kinds, the degree of resistance set up being favoured by its constant internal environment, by its normal antibody content, stimulated by antigens, and by the presence of antitoxins. Such resistance is reduced by any lack of balance due to defective nutrition, to intercurrent disease, or to the susceptibility of the individual.

We now have at command protective inoculation against a number of diseases—e.g., small-pox, anthrax, plague, cholera, typhoid, rabies, and diphtheria, by attenuated virus in small-pox and rabies, and by the dead bacillus as immunising agent in the other conditions. In all these cases the antibodies in the blood do not act alone in antagonising the toxic invasion, they are aided by accompanying cellular changes in the body itself. In the development o acquired immunity we see, in fact, an intensificatio of the defensive actions and properties possessed b the body in its natural state, which continue afte the antibodies have disappeared from the blood. I is common knowledge that the principles of activ immunity have now been directly applied, as a resul of the work of Sir Almroth Wright, in the treatmen of already existing infective disease in the form autogenous strains of the infecting organism, disi tegrated or killed. These act by aiding the loca defences of the tissues or stimulating the productio of antibodies in the blood. Such autogenous vaccin have been extensively used in the treatment of suc conditions as *acne, boils, tuberculosis, and* strept coccal, coli and gonococcal infections. The discover first, that bacteria invading the body produced gener effects by secreting a toxin which might pass into th system, and secondly, that the presence of such toxin stimulated in the normal body cells the produ tion of antitoxins and other antibodies whi antagonise or destroy the obnoxious toxin, is one the most arresting and remarkable of all the revelatio which the new knowledge has brought us. It is inde a confirmation and fulfilment of the Hippocrat doctrine that health and disease are both in them selves "divine," and the body is itself the healer disease.

Thus the physician is now active in the preventi aspect of healing; his drugs and remedies are n only prescribed for their preventive propensity, b they are specifically preventive in purpose. He n only appreciates the ramifications of infection, b he is vigilant to learn of the channel or vehicle which his patient has been infected. He takes t new knowledge of immunology and bends it prevention—he has become an immunisator. builds up the natural immunity of the body increasing the powers of resistance of the inter environment by recommending a physiologi regimen, and he supplies by artifice an acquir immunity. We are the witnesses of a new approa to disease, a new birth of medicine, *a treatm which is preventive,* undreamed of by Harvey a unavailable in this College two generations ago. all know the results, some of them dramatic and h toric throughout the world, some of them loc prosaic, and obscure, but on the whole profound beneficial in the reduction of the incidence a mortality of infective processes.

The Preventive Work of the College of Physicians

Before the days of the existence of the medic department of the Privy Council in 1858 the Colle was consulted frequently in regard to the practice *preventive medicine and the* administration of publ health measures by the City of London, the Priv Council, and Parliament. Its internal and design polity in respect of the Pharmacopœia, the registratio of the causes of death, implying the nomenclatu of disease, the prevention of plague and small-po and the control of alcoholism, has necessarily led to take an historic share in preventive medicine.

(I.) THE PHARMACOPŒIA

In the Letters Patent constituting the College in 1518 there was included a provision consigning to four persons named by the College the duty of "the correction and government of physic and its professors (practitioners) together with the examination of all medicines and the power of punishing offenders by fine and imprisonment." This duty, confirmed by statute in 1522, was discharged by the College for 340 years, until 1858. In 1540 the College was empowered by statute to destroy any defective drugs, and its authorised visitors were the forerunners of the inspectors and analysts under the Sale of Food and Drugs Act of 1875 and succeeding legislation. In 1585 the College found it necessary to fortify the censors, and guide all others concerned, by publishing a uniform Pharmacopœia, the drafting of which was assigned to a committee of six Fellows. Circumstances occurred to delay their labours, and the matter remained in abeyance until 1614, when a new committee of eight Fellows was appointed, including Harvey himself, and in four year's time they produced the first Pharmacopœia, Sir Theodore Mayerne writing the dedication. It comprised 1028 different articles, "some of them of extraordinary and even revolting character," and 200 of the preparations contained from 10 to 50 ingredients each. Subsequently nine editions were published from 1650 to 1851. The Medical Act of 1858 transferred the duty from the College to the General Medical Council.

For the first 170 years these Pharmacopœias followed the traditional custom derived from the Arabians, being an inventory of drugs used and approved for the time being. But the editions became both more scientific and more directional in 1788 and 1836. The chemical learning of the day was steadily introduced into the Pharmacopœia under the labours and erudition of George Baker, George Fordyce, Tuthill, Ayrton Paris, and Clement Hue. The last two held strong views on the uses of materia medica. In 1819 Paris was appointed to a special lectureship in pharmacopœia at the College, and delivered his revolutionary doctrines on "The Philosophy of the Materia Medica"—an epoch in the history of the science and art of prescribing, as Munk has said. The Pharmacopœia of 1836 was marked by the admission to its pages for the first time of the alkaloids, aconite, quinine, morphia, strychnine, hydrocyanic and phosphoric acids, iodine and bromine preparations, creosote, ergot, and lobelia. Thus was introduced into practical pharmacology in England that new philosophy of the art of therapeutics which is designed to control the internal forces which affect the body or its organs injuriously by means of counteraction, neutralisation, or prophylaxis.

Since the General Medical Council took over from the College, under statute, the duty of authorising a Pharmacopœia they have produced six British Pharmacopœias from 1864 to 1932. If the latest and current edition be compared with the Pharmacopœia of 1836 it will be observed that inter alia it is characterised by two new features. There has been a substantial increase in the number of authorised prophylactic drugs, such as cod-liver oil, liver extract, salvarsan, sanocrysin, atropine, and glucose; and it contains for the first time a new category of biological agents of a directly preventive nature, the use of which has greatly strengthened what the compilers of the reformed Pharmacopœia of 1836 called "the armamentarium of the physician," particularly in respect of artificial immunity. For among these biological substances are the vaccines, antitoxins, and antibacterial sera, thyroid and parathyroid extract, insulin, adrenalin, and pituitrin, now standardised under the Therapeutic Substances Act of 1925.

(II.) REGISTRATION OF CAUSE OF DEATH AND NOMENCLATURE OF DISEASE

The year before Queen Victoria came to the throne Parliament passed an Act for the registration of births and deaths, a natural corollary to the census of 1801. Births and deaths had been partially registered in the parish records of England since the days of Queen Elizabeth. But many of these church registers having been lost, the Act of 1836 was passed to make the record secular and complete, independent of religious opinion. Thus did the legislature of England, in the words of Dr. William Farr, "take the lead in advancing the health of Europe."

But it was not the Act of 1836 which secured this, for it alone was insufficient. In the spring of 1837 the Registrar-General wrote to the College of Physicians soliciting the aid of "every practising member of any branch of the medical profession" in sending to the local registrar of deaths "a written statement of the *cause* of death" of any person upon whom he was in attendance. On May 1st Sir Henry Halford, the President, jointly with the President of the College of Surgeons (Sir Astley Cooper) and the Master of the Apothecaries (Dr. Hingeston), issued their memorable circular to the profession asking all practising medical men to enter on the death certificate the authentic cause of death. They claimed that the important object of such returns, when collated, would be more accurate knowledge (1) of the comparative prevalence of various mortal diseases in England and Wales; (2) the localities where they prevailed; and (3) the age, sex, and condition of life principally affected. Here, then, was a statistical method which, as Farr pointed out in his report to the Registrar-General in 1839, gave the State for the first time the necessary foundation for modern nosology and epidemiology, for treatment and for prevention. For the voluntary practice thus initiated by the College (fulfilling, as it happens, an intention declared by the College in the sixteenth century) the Registrar-General officially and publicly thanked the medical profession, and after a generation of experience Parliament, in 1874, made statutory provision requiring the *medical certification of the cause of death* in all cases. It is this registration of the *cause* of death by the medical practitioner which lies at the back of the application and direction to-day of public health measures for communal health.

When at the Registrar-General's request, Farr undertook the task of classifying the causes of death returned by the medical profession in 1837, he was faced with the immediate necessity of an appropriate Nosology, using at first that of Cullen. Subsequently he tried the "Physiological System of Nosology" of 1820 by Dr. Mason Good, dedicated by permission to the College of Physicians, of which he was a distinguished and scholarly licentiate. In 1840 Farr adopted a classification of his own design, "the English classification," revised after the international statistical congress at Brussels in 1856. In the following year a letter was addressed to the College of Physicians by the Epidemiological Society, representing the medical advisers of the Army, the Navy, the Registrar-General, and the East India Company, asking the College to "take charge of drawing up a Nomenclature of Diseases for use in the military services and in civil life." In response the College appointed a committee on July 9th, 1857, of which Dr. Francis Sibson, friend and pupil of Thomas Hodgkin, was secretary. Its meetings were suspended temporarily in 1858, but by 1869 the new nomenclature of diseases was ready, and on March 6th Her Majesty's Treasury approved of its gratuitous distribution among 20,000 registered practitioners in the United Kingdom. Sir Thomas Watson was chairman of the committee and Dr. Farr was the principal adviser. Statistical data and uniformity of nomenclature are great things, but accurate diagnosis and the correct certification of the cause of death are greater. For this is the first and most fundamental factor in any scientific form of control. It was largely because of this public-spirited contribution by the College of Physicians that the Registrar-General's reports became the basis of the application of preventive medicine in England and in civilised States throughout the world.

(III.) THE PLAGUE

The contribution of the College to preventive medicine was, however, even more direct than its polity. The plague was prevalent in England from 1348–1666. From the experience of Wolsey and letters from Erasmus and Sir Thomas More, we know that when the College was founded by Henry VIII. there was prevalent in London the third outbreak of the sweat and the plague (which prevented the king from coming to London). In 1518 the King himself, on the advice of his physicians, had recommended the marking of plague-infected houses and preparatory arrangements for quarantine, a recommendation which became the first plague order in 1543. In 1529 the King urgently consulted his College of Physicians as to what means they advised for the prevention of this disease. The Privy Council in 1532 also on their advice ordered the issue of plague-bills, the first of a long series which were succeeded by the registration of plague deaths in parishes (1539). In 1563 the College was satisfied that there was some relation between animals and human plague, and recommended the destruction of dogs and cats. Under the more vigorous preventive policy of Elizabeth the Privy Council instructed the Lord Mayor of London to close infected houses, consider the necessity of establishing an isolation hospital, and appoint special medical officers to deal with the disease. The Lord Mayor consulted the College as to the number and personnel of these officers.

From 1630 to 1665 the College of Physicians issued advices periodically as to the prevention of plague. It is true that many of their recommendations were derived from former practices of somewhat mediaeval character, such as the sovereign remedy of flight, the marking of infected houses and persons, the appointment of "searchers," strong-smelling fumigations, and the necessity of sanitary cleanliness. The control of animals and tainted food, the removal of "annoyances," and the speedy burial of the dead emerged from current belief that they served as sources of infection. The medical profession were by no means unanimous as to the best course to take, and Fellows of the College were not always, then as now, in complete agreement with one another. They were roundly abused by Dekker, the dramatist. Yet we have from Licentiates or Fellows of the College the best records of current medical knowledge of plague. Thomas Lodge first studied arts at Oxford and law at Lincoln's Inn. He was a poet and dramatist, and from his *Euphues Golden Legacie*, Shakespeare constructed his *As You Like It*. Subsequently he studied medicine at Avignon and in 1603 he wrote a treatise on the plague, of which he died in 1625. Like Skene, 30 years before, he notes that a prevalence of plague is indicated by rats forsaking their holes. He advocates as preventive measures the removal of shambles from the city, sanitation, ascertainment of plague cases, the disinfection of bedding and clothes, and the discreet but compulsory removal of patients to isolation hospitals to be publicly provided.

Sir Theodore Mayerne advised the King as to prevention of the plague in 1631, and Wharton, Witherley, and Hodges, also Fellows of the College, remained in London during the plague of 1665 and were active in the prevention of its spread. Richard Mead did not live in the time of the plague, but owing to public alarm as to possible invasion in 1720 he was, whilst censor of the College, commissioned by the lords of the Regency to advise the Government, and in his Discourse on the Plague he summarised the medical knowledge of his age.

He recommended the appointment of a Council of Health to ascertain and register the cases and provide for their isolation, and for the destruction of infected goods, and the disinfection of bedding and clothing. The suppression of vagrancy and the institution of sanitary cordons round infected districts and quarantine, also among the recommendations, have proved the ancestors of modern methods.

(IV.) EXCESSIVE SPIRIT DRINKING

In 1725, under the presidency of Sir Hans Sloane, a representation from the College upon the evils produced by the excessive drinking of spirits resulted in the passing of the Gin Acts, the suppression of gin-shops, and the restriction of private retail sales. In face of a similar social problem, 190 years later, a group of Fellows of the College were consulted as to the appointment and work of the Liquor Control Board (1915–1918). The effect of that Board in securing a sober people is well known to us all.

(V.) SMALL-POX AND VACCINATION

Inoculation of diminutive doses of small-pox serum for the prevention of natural small-pox was introduced into England by Timoni, a Greek of Constantinople, in 1713, and was practised tentatively, and then fell into abeyance by 1740. It was reintroduced by Kilpatrick of South Carolina, and Frewen, a pupil of Boerhaave in 1743. In 1754, when small-pox was a scourge in England, the College of Physicians in a formal minute pronounced inoculation to be "highly salutary to the human race." In 1755 Dr. Robert Taylor delivered the Harveian Oration, remarkable for its vigorous promulgation of the practice of inoculation. Forty-three years later (1798) Jenner announced his method of vaccination with the serum of cow-pox as a means of protecting the human constitution from the infection of small-pox. This was substituted for the method of small-pox inoculation. Jenner also began forthwith the organisation of communal vaccination. Four years afterwards (1802) the House of Commons resolved, on the advice of the Prime Minister (Mr. Addington) that on Jenner's petition (March 22nd, 1802) it would call for a report from a committee of the House on the validity of vaccination. Subsequently Parliament preyed the King to "direct His Royal College of Physicians to inquire into the state of the vaccine inoculation in the United Kingdom, and to report their opinion as to the progress which it has made, and the causes which have retarded its general adoption." The College replied in 1807, and their memorable answer, which was the beginning of their leadership in small-pox prevention, closed with the following words :—

> "From the whole of the above considerations, the College of Physicians feel it their duty strongly to recommend the practice of vaccination. They have been led to this conclusion by no preconceived opinion, but by the most unbiased judgment, formed from an irresistible weight of evidence which had been laid before them. For, when the number, the respectability, the disinterestedness, and the extensive experience of its advocates is compared with the feeble and imperfect testimonies of its few opposers; and when it is considered that many, who were once adverse to vaccination, have been convinced by further trials, and are now to be ranked among its warmest supporters, the truth seems to be established as firmly as the nature of such a question admits; so that the College of Physicians conceive that the public may reasonably look forward with some degree of hope to the time when all opposition shall cease, and the general concurrence of mankind shall at length be able to put an end to the ravages at least, if not to the existence, of the small-pox."

Following on this declaration signed by Sir Lucas Pepys, president of the College, there was a debate in the House of Commons on June 9th, 1808, in which Mr. Rose secured the assent of the House to a resolution, "that public benefit would be derived from the establishment of a central institution in London for the purpose of rendering vaccinia inoculation generally beneficial to His Majesty's subjects." On this resolution the Privy Council called upon the College of Physicians to appoint a medical board to inquire into the methods of vaccination generally used, with their success or failure, and to organise and set in action a central institution for carrying on in London, under their own immediate superintendence, the practice of vaccination, and for distributing vaccine lymph to every part of the Empire. In 1858 Mr. John Simon, the medical officer of the Privy Council, was associated with the board; it made its last report to the Privy Council in 1860, and in the following year, on the death of the registrar, Dr. Clement Hue, the Privy Council itself took "the affairs of the Establishment under their own immediate direction."

Thus for more than fifty years the College of Physicians became the pronounced advocate of vaccination, undertook to initiate the control of the national movement for vaccination, inquired into its results, supervised its working, and standardised and distributed the lymph. Subsequently, these duties were undertaken by the Privy Council from 1861 to 1871, by the Local Government Board from 1871 to 1919, and since that date by the Ministry of Health.

Closely allied to this remarkable service of the College was their action a generation later in respect of antitoxin for diphtheria. In 1886 a deed of arrangement was drawn up between the Royal College of Physicians and the Royal College of Surgeons for the establishment of a conjoint board for the purpose of conducting their joint examinations or "for any other purposes of the Colleges as they may from time to time jointly agree." One of these other purposes was the establishment of laboratories for investigational work. In 1890 Dr. (afterwards Sir) Sims Woodhead was appointed as director, and in 1894 he and his colleagues, with the generous financial assistance of the Goldsmiths Company, began their work in the standardisation, preparation, testing and distribution to London hospitals of antitoxin for diphtheria. This voluntary task of the College proved invaluable in promoting the usage of this therapeutic and prophylactic means, hardly less effective in result, though proportionately less in degree, than the establishment of vaccination for small-pox. In 1890 the conjoint board of the two Colleges rendered powerful aid to the administrative and educational aspects of communal preventive medicine by creating a special diploma in public health (under the Medical Act, 1886), followed subsequently by a comparable diploma in tropical medicine and hygiene

Communal Medicine and Individual Practice

Throughout its history the College of Physicians has been the foster-mother of sound medical practice, and in each of its four centuries has nurtured and cultivated the Renaissance spirit of true learning and inquiry. When Linacre met Hermolaus Barbarus in the Vatican library he contracted a friendship which influenced his life, and in Florence, Rome, and Padua he drank at a more living source than he had found in Oxford. Its dynamic effect not only revived the spirit of the Oxford Reformers, but had much to do with the foundation of this College and the introduction of Greek medicine in England. From its earliest years it has had many Fellows or Licentiates who have contributed to the advancement of the science and art of medicine, and not a few who have moved forward our knowledge in physiology and pathology and their applications to preventive medicine. Among them should be especially commemorated the group of men, such as Harvey, Chamberlen, Manningham, Smellie, and William Hunter, who prepared the way in obstetrics for the prevention of puerperal fever; Lodge, Hodges, Wharton, and Mead, who established the defences against plague; Sydenham, Greaves, Heberden, Fothergill, Murchison, Willan, and Watson, who *differentiated the epidemic fevers and laid the basis* for their control; a long line from Harvey to the present day, who opened the doors of physiology; and George Baker, John Pringle, Southwood Smith, Edmund Parkes, J. H. Bridges, Patrick Manson, William Leishman, and David Bruce, devoted Fellows of the College, who left behind a splendid harvest of national and international preventive medicine. Named or unnamed these are the workers whom we commemorate to-day, and whose works do follow them. But their works follow them in a new world. The extraordinary advance in the science and art of medicine has supplemented the work of the family physician of a former day by providing an extensive system of general and special hospitals, laboratories, sanatoria, and clinics, with a no less comprehensive system of specialists on the one hand, and public medical services on the other. Yet the family physician will always remain the most economic and effective physician for the vast majority of human ailments. In any event, the registered medical practitioner will be the first into whose hands will fall the recognition and treatment of the beginnings of disease. Moreover, the practice of medicine must always remain both *inductive* and *individualistic.*

There is evidence that the State appointed public doctors at least as early as Democedes (c. 510 B.C.) and the custom was extensively followed throughout the Roman Empire. In England the first obvious intervention by the State was in the sixteenth century on account of the existence of certain foci of disease among the poorest and most vagrant class of the community, neither able nor willing to obtain medical advice and yet contributing to the spread of disease in the community. It became apparent that the State was the only available authority which could direct the application of advancing medical knowledge and practice to the problem. In the first half of the nineteenth century such action of the State became more formal and statutory, both in providing medical and surgical treatment for the poorest classes and in formulating sanitary measures to protect the whole community against insanitary environment or the spread of infectious disease. This profound and far-reaching development of a communal medical service has proceeded alongside the work of private practice. Since 1834 there has been a poor-law medical service, and out of it a few years later emerged the public health service, which in recent times has incorporated a number of special medical services, including those for maternity and child welfare, for the school-child, and for health insurance, each of which had begun in a voluntary form and grown spontaneously before the State had recognised its validity. No single person and no single movement is responsible for this creation or its development; it has emerged as part of the social evolution of the time in which we happen to live. Speaking generally, however, it is expedient that certain principles should be recognised in any public medical service.

(*a*) The province of the State should be to bring the physician and the patient together under circumstances which will be acceptable to the patient, whilst facilitating and safeguarding the work of the physician.

(*b*) The State should encourage the provision of the necessary hospitals and clinics with proper equipment.

(*c*) No one, not even the State, should come between the physician and his patient, whether in private or in public practice. For the physician (and not the agency, whether voluntary or statutory, which brings his patient) must both diagnose the morbid condition and prescribe effective treatment.

(*d*) The State should exercise supervisory administrative control if the medical service in which the physician is engaged is communal or is paid for, partly or wholly, by rates or taxes.

There is nothing here which in principle departs from the primary and paramount benefit of the patient, or invades the reasonable prerogatives of the physician. Indeed, in the English health insurance system there is free choice of physician and patient; advice, treatment, and prevention within the compass of the knowledge and experience of the private practitioner; and the maintenance of the responsibility of the patient, through his contributions, for the payment of the practitioner. Moreover, the system is such that it imposes a check on excessive claims of patients and on protracted benefit received during incapacity; in administration it is free from political control, for the management is in the hands of the contributor and the physician, as well as statutory bodies and the State; it provides for the education of the people in hygiene by their own physicians; and, lastly, it is so designed as to provide facilities for the initiation of research, and the keeping of fuller clinical records than in the past. Such a system cannot *insure*, or indeed be ultimately effective, any more than private practice can be ultimately effective, unless the principles of preventive action in regard to the processes of disease in the individual are recognised and practised.

It is obvious that numerous problems lie in front of the development of the coöperative association of the private practice of a former time with the public medical services of a new epoch. One thing is clearly necessary and even predominant—namely, mutual coördination between all channels and means of medical activity, in order that the integrity and goodwill of the healing art may be maintained, and that the patient, be he rich or poor, may receive the full advantages of the science and art of medicine which have become available since the days of Harvey's demonstration of the circulation of the blood.

BIOLOGICAL TYPES OF DIPHTHERIA BACILLUS

AND THEIR CLINICAL SIGNIFICANCE

By Helen A. Wright, M.B. Edin., D.P.H.

and

Adam L. K. Rankin, M.D. Edin., D.P.H.

(From the Bacteriology Department of the University of Edinburgh and the Edinburgh City Fever Hospital)

Attention has recently been drawn by Anderson, Happold, McLeod, and Thomson[1] to the occurrence of different biological varieties of the diphtheria bacillus associated with clinical types of the disease which differ in severity and response to antitoxin treatment. They described two main types having apparently distinct and characteristic colony forms when grown on a special tellurite blood medium. They named these *B. diphtheriæ* "mitis" and *B. diphtheriæ* "gravis," associated respectively with mild cases, and severe cases giving a poor response to antitoxin treatment. They also described the occurrence of "intermediate" types. They claimed that all these types are constant and have definite characters. The gravis and mitis types were characterised as follows:—

Gravis.—Colonies after 48 hours' growth on the special tellurite medium were grey or greyish-black and showed a daisy-head form; the bacilli were short, and when grown on Löffler's serum medium their metachromatic granules were either well marked or scanty; non-hæmolytic; fermented glucose, galactose, maltose, but not saccharose; also fermented dextrine, starch, and glycogen, but not d. glucosamine; broth cultures showed pellicle formation with granular deposit and reversion to an alkaline reaction in two days.

Mitis.—Colonies after 48 hours' growth on the tellurite medium were black; the bacilli when grown on Löffler's serum medium presented the morphological features generally regarded as typical of *B. diphtheriæ;* hæmolytic; fermented glucose, galactose, maltose, but not saccharose; also fermented d. glucosamine, but not starch or glycogen; inconstant results with dextrine; broth cultures showed a uniform turbidity and the acid reaction persisted for 4–5 days.

The *Intermediate* types exhibited some characters of mitis and some of gravis.

These findings, if substantiated, are not only of practical importance and significance in the ætiology and treatment of diphtheria, but might be regarded as almost revolutionary in regard to our knowledge of the bacteriology of the disease.

A study of a series of strains of diphtheria bacilli isolated from different cases in Edinburgh has been carried out following closely the methods used by these workers, and the data correlated with the clinical records of the cases.

METHODS

Unselected "positive" cultures on Löffler's medium were taken from those made for the routine examination of diphtheria cases.

Plates of the special "chocolate" tellurite medium as used by Anderson et al.[1] were inoculated from the primary cultures and examined at the end of 24 and 48 hours; colonies of *B. diphtheriæ* were picked off on *Löffler* and agar slopes. The cultures were examined microscopically at the end of 24 hours, and subsequently hæmolytic and fermentation tests were carried out. The growth in broth was observed and the time taken for the original acid reaction to revert to alkaline was determined. Each strain was also tested for virulence.

---

[1] Anderson, J. S., Happold, F. C., McLeod, J. W., and Thomson, J. G.: Jour. Path. and Bact., 1931, xxxiv., 667.

Simultaneously, but independently, full clinical records of these cases were kept at the City Hospital, the bacteriological and clinical records being compared at the end of the investigation.

The media used throughout were similar to those described by Anderson et al. The tellurite medium was prepared from Witte's peptone and horse blood instead of rabbit blood. When the strains had been isolated, a batch of this medium was made using rabbit blood and peptone (Parke, Davis and Co.), as in the original formula, and the strains replated on this.

Broth cultures.—The broth used at first was "Lab. Lemco" bouillon with 1 per cent. peptone, phenol red being added as indicator; but good growth at a pH suitable for this indicator (7·2) was not obtained. Hydrocele fluid was therefore added, and the strains all tested in this but at varying times after isolation. An initial increase of the original acid reaction was observed to occur within 24 hours of inoculation.

Fermentation tests.—Hiss's serum water was used with 1 per cent. peptone (Parke, Davis and Co.) and the particular carbohydrate added. Phenol red was used as indicator and the pH was 7·2. Difficulty was encountered with saccharose and starch, several kinds of each being tried. Easily fermentable products of hydrolysis were evidently produced by even a minimum of heat sterilisation, and gave equivocal results. Finally starch (British Drug Houses, A.R.) was used, and both the starch and saccharose media were sterilised by filtration only. The finished starch medium produced a brown-purple reaction with iodine. Dextrine and d. glucosamine were not used.

COLONY TYPES

Cultures kindly supplied by Prof. J. W. McLeod, which had been subcultured for several months on agar, yielded cultures (36–48 hours) on the special medium as follows:—

1. *B. diphtheriæ* mitis.—A fairly large, black, smooth, round, flattened colony, with a somewhat nippled centre, steeply sloping sides, and narrow, flattened, entire grey margin.
2. *B. diphtheriæ* gravis.—A greyish-black, smaller, less smooth, domed colony with domed black centre and wide grey, sloping irregular margin, showing some radial striation. No definite "daisy-head" form was observed, but older colonies tended sometimes to show a sunken ring in the centre.
3. The *intermediate* form produced a much smaller colony, greyish-black with domed centre, somewhat irregular margin and some radial striation.

The medium containing rabbit blood and peptone (Parke, Davis and Co.) tended to produce a less smooth type of colony and to show more markings and radial striations.

Among the series of strains isolated from cases in Edinburgh, colony types were observed which were similar to those of the standard cultures described above: type I. corresponding to gravis, type III. corresponding to mitis, and type II. being intermediate. Very considerable difficulty, however, was found in classifying the colonies, as a great number of varying characteristics was encountered.

BROTH CULTURES

The broth cultures also showed great differences, and a gradation from clear fluid with coarse granular growth and deposit, to uniform turbidity with fine granular deposit, and uniform fine granular turbidity. Pellicle and ring formation was found with examples of each kind of growth.

CELL MORPHOLOGY

The cell morphology in Löffler's serum cultures (24 hours) stained by Neisser's method showed great variations from the "text-book" form (long, thin, slightly curved bacilli with definite bipolar granules) to straighter, thicker, less definitely staining organisms of very varying length. Some almost coccoid forms were met with. In these less typical forms the number of granules was very varied, in some strains appearing only in a few individual organisms. These were usually small, and did not protrude beyond the cell body.

The differences and gradations especially in colony formation and growth in broth require to be stressed to show the difficulty found throughout in classifying the different strains with anything approaching accuracy.

STRAINS ISOLATED

Strains which did not ferment glucose, galactose, and maltose, or which fermented saccharose, were

(2) *Clinical examination of the infant must be* complete and thorough, in order to exclude examples of secondary hæmorrhage—e.g., sepsis, syphilis, gastro-enteritis—genital crisis of the new-born, and mouth injuries.

(3) The age of the patient must be less than 7 days when bleeding begins. The only possible exception is the rare case of umbilical hæmorrhage beginning when the cord-stump separates.

(4) In slight cases of hæmatemesis or melæna the mother's nipples must be examined for cracks or fissures which may have caused "spurious" neonatal hæmorrhage.

Frequency.—Various *authors state the frequency* as 1 in 600 to 1 in 300 births. In my series I can make the calculation only on the 22 babies born in the Maternity Hospital, and for these the frequency is 1 in 520 births.

Sex.—The sexes are equally affected.

Maternal and obstetrical influence.—I do not find that the age or general health of the mother has any bearing, but it is of some interest to note that 16 out of the 28 babies were either the first or second born. Neither the character of the labour nor the type of anæsthesia given to the mother seems to have any influence; all types of labour, including one birth by Cæsarean section, appear in my series.

Condition of infant.—The babies are generally full-term and of good size; this is somewhat surprising, because one might expect fragile prematures to be more often affected. Usually the baby seems to be in perfect health up to the beginning of bleeding; the average age of the child at onset of hæmorrhage (26 cases) was 37½ hours. In one twin-birth (probably monovular) both babies were affected; in another (binovular) only one baby suffered.

Type of bleeding.—Nearly all were cases of melæna, with or without hæmatemesis. There were three examples of umbilical bleeding and one of vaginal; in two cases epistaxis, or urethral or subcutaneous and submucous hæmorrhage, accompanied melæna.

ÆTIOLOGY

I made reference in my previous paper to some of the theories offered to explain the hæmorrhagic disease, but no final conclusions have yet been reached. It is said that in about 40 per cent. of the cases which come to autopsy diligent search will show a very small gastric or duodenal erosion, or an area of hyperæmia which may have been responsible (see Kennedy,[8] Steiner,[16] Bonar,[2] Ritter v. Reuss,[15] Rhenter,[14] and Kobes [9]). This evidence, however, is inconclusive because, if it were possible to make the necessary examination, a similar change might be found in all new-born babies as a result either of the tying of the umbilical cord or of ascending intestinal bacterial assault. Some support for this possibility is provided by careful chemical testing of the fæces of healthy neonates; this has demonstrated traces of blood in 29 per cent. to 64 per cent. of specimens submitted to examination (Bonar [2]; Högler [7]).

Some workers have assumed a low form of alimentary infection—from blood stream, from umbilicus, or from the contents of the intestine—to be responsible, and the work of Hare and Glynn [6] upon lamb dysentery is of interest in this connexion. Definite examples of gastro-enteritis are seen in new-born babies from time to time, but these present a clinical picture which is quite different from that of hæmorrhagic disease, and up to the present the infective theory must be regarded as inadequate.

Recent work on vitamins has led Moore and Brodie [13] to suggest that a lack of vitamin B in the mother's diet may be responsible, for they claim that this avitaminosis results in deficiency of prothrombin in the baby.

It seems likely that fruitful results may be expected from further investigations of blood characteristics in neonates. A number of contributions have appeared (Grob,[5] Maurizio,[12] Beveridge,[1] Kugelmann and Tritsch,[10] Carr,[4] in addition to those mentioned in my previous paper), but no definite conclusions have been reached. These investigations must be carried out by an expert and it is often very difficult in actual practice to obtain specialist services of this kind at short notice. There seems to be little doubt that the bleeding tendency of most babies, as indicated by the coagulation and bleeding times, is increased during the first ten days of life; but a mere increase of this tendency does not seem sufficient to explain the onset of a disease which occurs only once in every 500 infants born.

TREATMENT

Citrated whole blood, obtained from mother, father, or any other healthy donor, should be injected intramuscularly and subcutaneously as soon as the bleeding is noted. It is most important that treatment should not be delayed. The requisite amount of citrate is easily obtained by dissolving a 2-gr. sodium citrate tablet in 3 c.cm. of water, and using 1 c.cm. of this solution for every 10 c.cm. of whole blood. The injection may be made into the outer aspect of the thigh, and it is wise to introduce the needle below the midpoint of the thigh, in a cephalic direction, in order that the puncture may be outside the napkin area and so out of danger of infection. When it is necessary to repeat injections different masses of muscle should be used—for instance, the deltoid region and the abdominal wall. The volume of blood required varies from case to case: in a severe example 20 c.cm. should be given at once, and doses of 10 c.cm. may be repeated every two hours as necessary. Twenty-seven out of my 28 cases were treated by blood injection, and the average volume given per patient was 29 c.cm. The largest volume received by any one infant was 85 c.cm. On two occasions I have transfused the donor's blood into the baby's superior longitudinal sinus, but the operation is difficult, dangerous, and not to be recommended (see Voron and Banssillon [17]). When the injections are made subcutaneously and intramuscularly preliminary typing of the bloods is not necessary.

It is most difficult to assess the value of blood injection because it is agreed that a number of cases, even serious ones, will recover without any special treatment. The physician may unwittingly persuade himself to the view so commonly held by the laity that when hæmorrhage ceases shortly after the injection of blood there must be an intrinsic relationship between the two incidents. Although no such relationship has yet been proved definitely, there are three clinical facts which lead me to believe that this form of treatment is efficacious:—

(1) The death-rate is now definitely lower than it was before the introduction of blood treatment, though this reduction in mortality is offset to some extent by the fact that the older series probably contained a larger proportion of truly septic cases than are seen nowadays.

(2) In cases of umbilical bleeding, when the site of hæmorrhage is visible, I have seen cessation of bleeding within ten minutes of the injection of blood.

(3) I have been impressed in a number of cases by the general improvement which quickly follows the injection. It is not uncommon to find that the

restless irritable infant becomes peaceful and falls asleep within half an hour.

Although it would seem theoretically advisable in cases of melæna or hæmatemesis to permit rest for the upper part of the alimentary tract by withholding oral fluids, it must be remembered that contractions of the intrinsic musculature are probably increased by hunger, and it is clearly established that strict deprivation of fluids is more dangerous to the baby than feeding on rational lines.

If blood is injected immediately the diagnosis is made, it is not necessary to withhold oral fluids for more than three hours. The infant may then be given a 2-oz. feed of aspirated maternal milk, which should be repeated at two-hourly intervals for 24 hours. During this period the baby is not lifted from its cot, and care is taken that the supply of external heat, by carefully guarded water-bottles, electric lamps, or electric blankets, is adequate but not excessive. When breast-milk is not available a 10 per cent. solution of glucose in water may be used in the same dosage. Subcutaneous or intraperitoneal saline injection may be necessary in severe cases; rectal salines are seldom advisable. It is usually safe to lift the baby gently to the mother's breast about 24 hours after the onset of the illness, but the child should not be moved, even for this, if the local and general signs do not support the view that hæmorrhage has probably ceased.

Drugs given orally to control hæmorrhage are probably valueless. In umbilical bleeding a thorough trial should be given to local measures, such as ligature of the base of the cord and the application of hæmostatic substances (adrenaline. tannic acid, perchloride of iron, silver nitrate); but blood injections should be given in addition. During convalescence gr. 1 of reduced iron or iron and ammonium citrate should be given twice daily. Fresh air, sunlight, and a proper diet are clearly indicated, while carefully regulated doses of ultra-violet radiation may be valuable in some instances. Marmite, one half of a teaspoonful twice daily, has been employed in recent cases.

PROGNOSIS

The chances of recovery depend upon the weight of the baby, the amount of blood lost, the rapidity and adequacy of effective treatment by blood injection, and the presence or absence of infection or sepsis. My own experience during the past 12 years leads me to think that the disease is somewhat less severe than it was. Three deaths occurred in my series of 28 cases, giving a mortality-rate of 10·7 per cent.; my cases were consecutive examples and included a number of premature infants as well as one moribund baby seen in private practice.

TROPICAL ULCER AS A DEFICIENCY DISEASE

TREATMENT WITH INJECTIONS OF CALCIUM

By Leonard J. A. Loewenthal, M.B.,
D.T.M. & H. Liverp.

MEDICAL OFFICER, MBALE, UGANDA; LATE HON. ASSISTANT DERMATOLOGIST, LIVERPOOL CANCER AND SKIN HOSPITAL

Tropical ulcer (syn. tropical phagedænic ulcer) is a well-recognised clinical entity with a somewhat patchy distribution throughout the tropical and semi-tropical belts. The observations here recorded apply only to the Bugwere and Bugishu districts of Uganda, as my knowledge of conditions at first hand is limited to these parts, but I see no reason why the method of treatment here discussed should not be applied with equal success to other communities.

The morbidity-rate from this disease is admittedly enormous; its precise extent is unknown, but may be guessed from the fact that at every hospital and sub-dispensary in the two districts ulcer cases outnumber all other cases together by more than two to one. If left untreated, death ensues in nearly every case. Hospital records do not show a high death-rate from the disease because the patients usually run away after a few months' trial of hospital methods, and out-patients attend only sporadically; inquiries among the chiefs, however, elicit the information that these patients almost invariably die after returning to their villages. Speculation is often inaccurate, but there is good reason to suppose that in its mortality and morbidity tropical ulcer may take its place with malaria, plague, and trypanosomiasis.

ÆTIOLOGY

The disease attacks both sexes equally, especially during adolescence, a fact which should not be lost sight of when we consider it as a metabolic disorder. It has been confused in the past with syphilis and yaws, and it is difficult to decide what part these diseases may play in the ætiology of tropical ulcer among heavily infected communities. Nearly every variety of organism has, at one time or another, been blamed for producing this condition, but in no case has the evidence adduced been convincing.

A useful contribution to the ætiology of tropical ulcer is that of McCulloch,[1] who found in his cases a high figure for blood-sugar and a low one for blood-calcium and urea. His actual words are: "Tropical ulcer is a dietetic ulcer, and the question of causative organisms need not be considered at all." With these views my therapeutic results are in complete agreement.

The fact that spirochætes and fusiform bacilli, for instance, are found constantly in these lesions is of no scientific value ætiologically, for it is the exception for such organisms to be absent from any wound of skin or mucous membrane in tropical countries. Furthermore, I have not yet found, in the literature devoted to this subject, any evidence of more than one of Koch's postulates having been fulfilled. The undoubted fact that tropical ulcer may assume epidemic proportions should not prejudice opinion too strongly in favour of the bacterial theory, without investigation of the general conditions obtaining at the time of such epidemics. For example, the Carrier Corps of natives during the last war, in the years 1914–18, was said to have suffered from an epidemic of tropical phagedænic ulcer. But here we are dealing with a community removed from its natural surroundings and living under conditions of diet and climate widely different from those to which it is accustomed. It would be as rational to insist that scurvy and famine œdema were bacterial diseases, because they frequently assumed epidemic proportions.

A significant fact in the ætiology of tropical ulcer is that it is found almost exclusively among the poorest classes. The well-to-do native is as susceptible to other diseases as the poorest; he is usually infected with malaria, and frequently with syphilis. His mode of living is in many cases identical with that of the poorer native, with the sole exception of diet. Here the difference is startling. The average chief's diet in the Bugwere and Bugishu districts of Uganda, for instance, is as follows:—

Staple food.—Unripe bananas cooked, sweet potatoes. Daily milk.

Supplementary.—Beef twice weekly, chicken twice weekly, rice and eggs occasionally.

Most of the other natives, however, live on the following:—

Staple food.—Unripe bananas cooked, sweet potatoes. Milk only if they possess cattle.

Supplementary.—Beef perhaps once a month, often less.

Native beer is taken by both classes, and consists of various fermented vegetable products.

Hospital records show that tropical ulcer, as distinct from syphilitic and framboesial ulcer lesions, is never met with among chiefs or their families, while it constitutes one of the most frequent diseases among other classes.

A further significant point in the ætiology of this condition is found in the Buganda Province, especially in the neighbourhood of Kampala. Here the Baganda are, in the main, well-to-do, and have a good meat and milk ration in addition to bananas, rice, and sweet potatoes. Nearly all the menial work—e.g., that of porters—is done by immigrants from Ruanda, who receive a small wage and live on a purely vegetable diet without any supplement in the way of meat or milk. Among the ulcer cases seen in that part of the country, the vast majority are the Ruanda labourers, and extremely few are found to be local Baganda.

Taking all these facts into consideration, a dietary cause for tropical ulcer is at least as likely as a bacterial. We have, however, no direct guide to which element of the diet might, by its diminution or absence, be responsible for the disease. According to McCulloch's researches, calcium is constantly deficient in the blood of these patients, while the calcium content of the soil, in Uganda at any rate, is known to be poor. These last two observations are suggestive, but by no means conclusive, in attributing tropical ulcer to a calcium deficiency. As in other deficiency diseases, however, the therapeutic test adds considerable weight to what is, after all, mere speculation.

CLINICAL OBSERVATIONS IN SUPPORT OF A DEFICIENCY THEORY

(1) The onset of a tropical ulcer is usually ascribed to a pre-existing local injury, though in many cases no such injury has been present, and the ulcer in these cases begins as a small papule which in a short time breaks down and discharges a thin offensive fluid. This secretion is a product of tissue necrosis, and bears no resemblance to inflammatory exudates.

(2) According to other observers,[2] there is often a small areola surrounding the papule, but this I have never been able to see on the African skin. At all events, there are no other signs of an inflammatory reaction; pain is usually slight or absent at this stage, there is no increase of heat in the part, and lymphangitis and lymphadenitis are not seen.

(3) Rapid destruction of tissue follows, with a variable amount of pain, dirty slough and discharge, and an advancing edge which shows no evidence of an inflammatory reaction. Pain becomes a marked feature only when tendons, periosteum, or bone are involved. Later, œdema is usually present around the lesion, and later still, evidence of secondary infection may be observed. The whole aspect of the condition, however, is one of tissue necrosis on a large scale rather than of inflammation. The clinical picture of an old-standing case in the foot, for instance, is highly suggestive: the blackened necrosed stumps of the tarsal bones project from a mass of unhealthy granulations, among which may be seen the mummified remains of muscles and tendons. The patient is cachectic and exhausted, while the temperature remains normal or subnormal and general signs of a pyogenic infection are absent.

(4) Treatment locally with antiseptics does not produce any marked improvement. Thorough scraping, with removal of necrosed bone, may bring about slow healing, but as often as not the ulcer slowly regains its former characters and remains indolent until the patient dies of exhaustion or intercurrent disease. As an illustration of the indolent nature of these ulcers I may quote Langeron,[3] who by his local applications (which, incidentally, include calcium), reduced the time of healing of a 16 cm. ulcer from 240 to 91 days! General treatment has also proved disappointing. Salvarsan and other arsenical compounds do not produce rapid amelioration, while antimony, though successful in many cases when used for a long period, is by no means a certain cure. This fact should be given due prominence when considering the spirochætal or protozoal theories of causation of tropical ulcer.

TREATMENT WITH CALCIUM INJECTIONS AND RESULTS

In September, 1931, treatment of tropical ulcer with calcium injections was instituted at Mbale Native Hospital, and later at the seven sub-dispensaries in the Bugwere and Bugishu districts. In all, about 500 patients have so far received this treatment.

Method.—Calcium chloride grs. 15 in 10 c.cm. of distilled water are daily injected intravenously. For children, from 5 to 7 grs. are injected intravenously, according to age. Local treatment consists of eusol dressings twice daily only. The first few injections usually cause almost immediately a disagreeable feeling in the mouth and at the site of the ulcer. This is by no means a disadvantage among native patients, who consider it a sign of the efficacy of the remedy.

Results.—The first and most remarkable result of calcium treatment is the disappearance, in three or four days, of every trace of offensive odour. There have been no exceptions whatsoever to this rule; that this was not due to the eusol dressings is shown by the fact that many patients who had been under various treatments previously, including eusol dressings, without losing this stench, did so as soon as they received calcium injections.

Within the first week of treatment the slough separates, and healthy granulations appear in the base of the wound. Diseased bone separates spontaneously or, if merely patchy on the surface of a long bone, is absorbed. After ten days the ulcer is clean; there are no exceptions to this rule either. Healing of the ulcer begins from the edge, and is rapid in most cases, though a few, while remaining clean, heal very slowly indeed. This is partly due to the difficulty in keeping the patients in bed, and in several cases has been due to their scratching off the new epithelium as soon as it has formed. The general condition of the cases treated with calcium injections improved along with the local healing. Many, especially adolescents, gained weight, and showed a desire to return to an active life before the ulcer had completely healed.

Tabulation of results.—In assessing the results obtained and tabulating them satisfactorily, difficulty is experienced in several ways, a few of which I may mention here.

Ran away.—This is unfortunately a very common entry on the case-sheet when dealing with primitive African tribes. Some run away because they are tired of hospital after spending several months as in-patients; others run away after a few days because routine and diet do not accord with their tastes. These latter comprise all the cases marked "Ran away. No improvement," and had an average stay in hospital of only 1·4 weeks.

The second and larger class of "ran away" comprises those whose ulcers are practically healed, usually with only ¼ inch square of non-epithelialised surface remaining. These I have called *ran away; almost cured*, for statistical purposes, though for practical purposes they could be considered cures. To judge by other patients who had reached a similar stage in the progress of healing and did not run away, another week would have seen a complete cicatrix.

Almost cured.—These are cases similar to the above who, however, have not run away but still have a small area of non-epithelialised surface at the time of writing.

Improved.—In these cases the ulcer is clean and active healing is taking place, usually at the rate of ½ inch a week on the whole of the circumference. Many of these started as ulcers of 9 inches or more in diameter and, though healing well and perfectly clean, take some time to epithelialise completely.

The three patients who died were all old men, in very poor condition. Two succumbed to pneumonia and the third to diarrhœa, possibly due to amyloid disease; permission for a post-mortem examination could not be obtained.

The first 69 cases treated with calcium chloride injections are here discussed (see Table); 35 of them had had in-patient treatment with arsenical and other metallic compounds, as well as local dressings, for a period of up to six months. There was roughly an equal number of either sex. The number of patients treated was 69, the average age 19·2 years, the average previous duration of ulcer 8 months, and the average duration of calcium treatment 4·8 weeks.

—	Number and percentage.	Treatment (weeks).
Cured	15 (21·7)	4·3
Almost cured	8 (11·6)	7·0
Ran away; almost cured ..	13 (18·8)	4·4
Improved	10 (14·5)	6·5
Ran away; improved	12 (17·4)	4·3
Ran away; no improvement ..	5 (7·2)	1·4
No improvement	3 (4·4)	4·0
Died	3 (4·4)	6·1

N.B.—No improvement merely means that no healing has taken place. All the ulcers are clean and free from stench. Of the three cases thus tabulated, one ulcer is based on elephantoid tissue and one is clinically syphilitic, though no improvement took place previously on salvarsan and bismuth treatment.

As these cases did not all begin to receive treatment on the same date, and are admitted almost daily for a course of calcium injections, it is impossible to exclude such items as "almost cured." At whatever date statistics are taken there will always be comparatively recent arrivals who have not yet attained complete healing. It must be remembered that all cases marked "improved" are making steady progress from week to week.

Thus we may group the results in the following way:—

	Per cent.		Per cent.
Cured or almost cured	52·1	No improvement ..	11·6*
Improved	31·9	Died	4·4

* Of these several remained under treatment for less than one week.

The results obtained at the sub-dispensaries, in charge of native dressers, have been equally encouraging. The treatment lends itself to application on a large scale, providing that sufficient dressers experienced in intravenous therapy are available. Apart from the obvious advantages of this treatment, the saving in dressings and other more expensive drugs is sufficient to commend it in hospital work.

CASES

CASE 1.—Man, aged 18. Duration of ulcers, seven months. Previous treatment with antimony and bismuth, two months, without improvement. He had two ulcers, one on the left shin, measuring 3 in. by 2 in., and one on the left foot, which had amputated the middle three toes. Both ulcers were highly offensive and showed no sign of healing. Sept. 17th: treatment with calcium injections started. Sept. 28th: no smell; dry healthy granulations almost covering the base of each ulcer. Oct. 9th: active healing at the whole circumference of each ulcer. Nov. 4th: completely healed; discharged.

CASE 2.—Woman, aged 22. Brought her child to hospital as it was suffering from malaria and marasmus. She was feeding the child at the breast, and both were in a debilitated condition. One week after admission to hospital she developed an ulcer over the right external malleolus. Two days later a course of injections with salvarsan compounds and bismuth was started, and a month later, as there was no improvement, antimony was tried. After five months of treatment the ulcer measured 5 in. in diameter and, in spite of frequent dressings, was extremely offensive and lined with a dirty slough. Oct. 23rd: treatment with calcium injections started. Oct. 30th: all smell and slough disappeared, revealing some periosteal necrosis. Since then healing has taken place very slowly, possibly due to the drain of calcium through lactation. Incidentally the child, which had previously not reacted to treatment with quinine and cod-liver oil, began to improve within a week of its mother receiving calcium injections, and is now in good health.

On Dec. 22nd the mother's ulcer was half its former size, perfectly clean, and healing steadily.

CASE 3.—Boy, aged 15. Previous duration of ulcer nine years. Previously had antimony and bismuth treatment for four months without improvement. He had an ulcer measuring 11 in. by 8 in. on the front and inner side of the right leg, involving the tibia. He had several hæmorrhages from the exposed medulla, and on one occasion was found unconscious in the hospital grounds, having lost several pints of blood. Amputation was being considered, but in view of the successful progress of Case 1—our first case to receive calcium injections—it was decided to give this treatment a trial in his case. Sept. 28th: calcium injections started. Oct. 9th: healing began. Nov. 25th: the whole crater had filled with healthy granulations; epithelialisation was progressing rapidly, and the remaining uncovered portion measured 2 in. by 1 in. On this day he scratched the edges of the wound and infected it badly, so that almost the whole of the new epithelium stripped off. Dec. 22nd: healing has again taken place, and now the remaining unhealed portion is roughly the same as on Nov. 25th.

CONCLUSIONS

1. Tropical ulcer is one of the great causes of death and disability among African natives. 2. There is little evidence in favour of a bacterial cause, whereas its ætiology from the dietary point of view deserves consideration. 3. Treated by daily intravenous injections of calcium chloride, the great majority of patients showed rapid healing. This treatment constitutes a definite advance, in that it is superior to all others both therapeutically and economically. 4. Approximately 500 cases of tropical ulcer have received this treatment, and the first 69 personally observed are analysed.

I am much indebted to Dr. C. R. Wallace, senior medical officer, Mbale, for his enthusiastic help in arranging that

this routine calcium treatment should be carried out on all ulcer cases in the hospitals and sub-dispensaries under his control; for many valuable suggestions, and for his assistance in the production of this paper.

My thanks are also due to Major G. J. Keane, director of medical and sanitary services, Uganda, for permission to publish this paper.

HYPERTROPHIC PYLORIC STENOSIS IN ADULTS

BY MARK COLEMAN, M.S. LOND., F.R.C.S. ENG.
ASSISTANT IN THE SURGICAL UNIT, UNIVERSITY COLLEGE HOSPITAL

THIS condition has received scant recognition in England. On the continent attention was first directed to its possibility by Landerer in 1879; whilst in England, in 1904, Mayo-Robson and Moynihan described two cases. Since then a few isolated authentic cases have been reported in America, and Walton,[1] in his text-book of "Surgical Dyspepsias," remarks on two cases of his own. The following case possessed a complication not present in those so far described.

CASE RECORD

History.—The patient was a married man, aged 38, a platelayer, and he complained of periodical attacks of abdominal pain for seven years, with vomiting for the last two years. During the earlier years of this period upper abdominal pain came on regularly two to two and a half hours after meals. The periods of freedom from pain were as long as six months, but they had become progressively shorter, and the pain had increased in severity so that his appetite was affected. Eventually the pain became almost continuous; it was a dull gnawing ache, but became more acute within five minutes after a meal and induced belching and vomiting, which to some extent relieved it. Recently he has had typical "hunger pains" relieved by taking food or a bismuth mixture.

There was no history of hæmatemesis or evidence suggestive of melæna. Recollection of any gastro-intestinal disturbance in infancy was hazy and indefinite; 18 months before he had been investigated for supposed duodenal ulcer, and screening had shown suggestive evidence of a chronic ulcer low down on the lesser curvature with a tendency to spasm near the pylorus. It was considered that most of his symptoms were due to alcoholic gastritis, but strict dieting and abstinence from alcohol failed to ameliorate them.

Examination.—The patient was pale and thin and had a normal temperature. His teeth were mostly in good condition, except for slight pyorrhœa in the upper and lower incisors. The chest was long and thin and the epigastric angle narrow. No abdominal tumour was palpable, but there was a point of deep tenderness just to the right of the mid-line, a third of the way up between the umbilicus and the epigastric notch. No scars of previous laparotomy were present. There were no other physical signs. The test for occult blood in the stools was negative, as was also the van den Bergh reaction in the blood. The blood count was within normal limits. A fractional test-meal showed a small quantity of resting juice, absence of free HCl, a low total acidity, and fairly free regurgitation of bile. A barium meal showed a low hypotonic stomach with persistent contracture of the greater curvature near the pylorus. There was no deformity of the duodenal cap or delay in emptying of the stomach. No ulcer niche was seen, but the spasm was thought to be due to a pyloric ulcer.

Operation.—Mr. A. J. Gardham operated on Nov. 27th, 1931, and found a firm elastic mass surrounding the pylorus, ending abruptly on the duodenal side but gradually thinning and extending for some 1½ inches on the stomach side. The peritoneal surface was smooth and free from any evidence of inflammatory or neoplastic disturbances. Two small soft lymph glands were palpable in the subpyloric region. On the anterior surface of the stomach near the lesser curvature and 3 inches from the pylorus the stomach wall was thickened and œdematous, and the peritoneum greyish-white, with punctate hæmorrhagic speckling; the lesser omentum opposite this region was thickened. The stomach was not dilated. Gastrectomy and anterior gastro-jejunostomy (using the Balfour modification of Polya's operation) was performed. The patient made a rapid recovery, and at the time of writing is completely relieved of symptoms.

Specimen.—The resemblance of the pylorus projecting into the duodenum to the cervix uteri projecting into the vagina was marked, but the orifice was circular and patent. The tip of the little finger, when pushed through this opening from the pyloric side, was gripped by what felt like a ring of unyielding tissue; there was no grating on cutting the pylorus. The cut surface showed the tumour at the pyloric ring to be due to a muscular hypertrophy fully half an inch thick, stopping sharply at the duodenum but fading gradually into normal thickness of muscularis on the stomach side. The mucosa showed a moderate degree of chronic gastritis, but was freely mobile over the muscularis in the region of the pylorus. The puckered scars of healed chronic gastric ulcers corresponded in position to the external appearances observed on the stomach. Fig. 1 shows the muscular hypertrophy clearly and the healed ulcers in the top right-hand corner.

Microscopical section (Fig. 2) showed very great hypertrophy of the circular muscle-fibres, stopping sharply at the commencement of the duodenum, as indicated by the presence of Brunner's glands. The same region was also demarcated by the longitudinal fibres of the stomach turning up towards the mucosa, and conceivably acting as a sphincter to the pylorus in this region. There was an increase of interstitial tissue between bundles of muscle-fibres, consisting mainly of compressed fibrous tissue and looser fibres mingled with cells which were endothelial in type; but there was no inflammatory exudate. The mucosa showed the changes of gastritis, and there was considerable lymphoid tissue in the submucosa and diffuse infiltration with chronic inflammatory cells, but no suspicion of malignancy.

COMMENT

Landerer regarded pyloric stenosis in adults without hypertrophy or dilatation of the stomach as a congenital deformity. Maier[2] in 1885 added 21 further cases, most of which came to post-mortem examination on account of non-gastric diseases. The gastric clinical histories, when known, are very sketchily described; but he recorded two young adults who had complained of abdominal pain since early youth, and several others with histories extending over many years. He concluded that there exist pure cases of round or slit-like congenital narrowing of the pylorus. These may be complicated by a congenital muscular hypertrophy or catarrh of the stomach; some are also combined with either a congenital or a very early acquired abnormal fixation of the pylorus, due to an extraordinarily thick *ligamentum hepaticum duodenale* and *gastro-hepatic omentum*.

Mayo-Robson and Moynihan[3] in 1904 described two cases: in the first, a child aged 11 years, who had suffered from infancy with general abdominal disorders and vomiting, laparotomy showed a muscular hypertrophy of the pylorus; in the second, aged 24 years, with five years' duration of symptoms, operation revealed a contracted pylorus without any evidence of organic disease. They considered that these conditions might explain dilatation and catarrh of the stomach in young adults, or the persistent vomiting usually labelled "hysteria" or "pernicious habit."

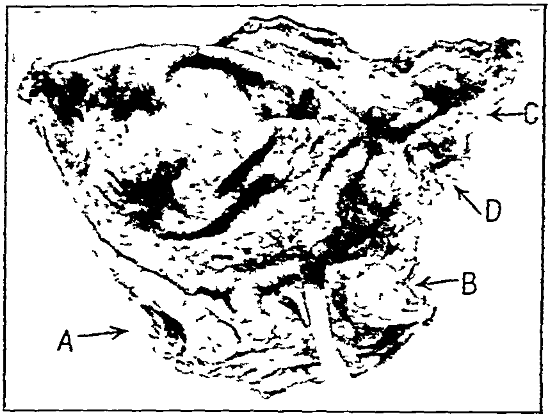
Maylard[4] mentioned 15 cases which showed at operation a dilated stomach without muscular hypertrophy, ulceration, or neoplasm, but a uniformly narrowed pyloric aperture (between 2 and 12 mm. in diameter), just admitting the tip of a finger. The interior of the stomach was inspected by direct vision in all these cases, and gastro-enterostomy completely relieved all symptoms. He thought his cases congenital in origin, but was careful to emphasise that they were in no way akin to hypertrophic pylorus stenosis, although he considered that the latter condition probably existed in adults.

Crohn[5] in 1928 recorded the case of a nurse, aged 45, who suffered all her life with epigastric pain and vomiting. Marked pyloric stenosis with gastric dilatation eventually developed. At operation a mobile pylorus, free from inflammatory changes but resembling an enlarged replica of the condition in infancy, was found. He believes this to be a case of mild congenital hypertrophic stenosis of infancy, not sufficiently severe to interfere with nutrition and managing to survive to adult life.

Mr. Julian Taylor recently told me of a child aged 6 years who was an undoubted case of pyloric stenosis of infancy, treated medically, and who still shows visible stomach peristalsis. Finally, Morton[6] (1930, two cases) and McClure[7] (1931, four cases) described examples in adults varying in age between 31 and 51 years, the duration of symptoms in two cases being throughout life and in the remainder from 12 years to 6 months. At operation all showed a hypertrophied pylorus without apparent organic cause.

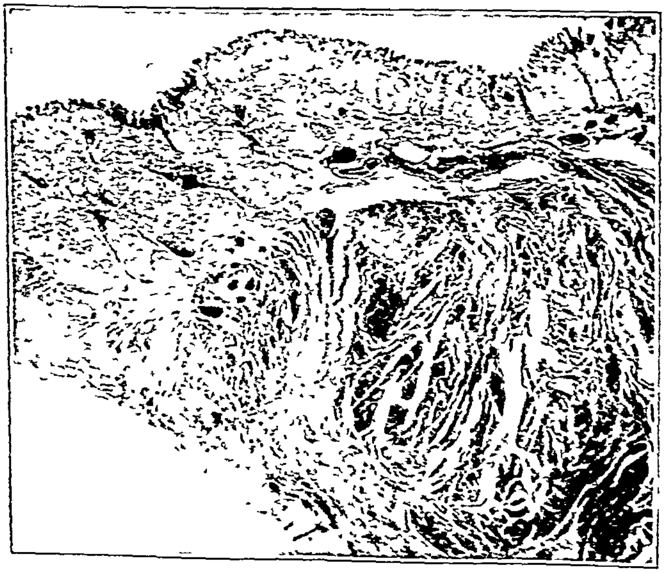
Omitting the cases of Maier and Maylard (of pyloric stenosis without muscular hypertrophy), there appears sufficient evidence to justify the view that the so-called congenital hypertrophy of infantile stenosis may persist throughout life. Probably there are patients with mild unrecognised pyloric hypertrophy in infancy who recover under medical treatment, and the condition may be only discovered at autopsy after death from some other disease. Some, less fortunate, complain of abdominal symptoms throughout life, whilst still others, after many years of freedom from symptoms, may undergo some complicating change that may demand surgical aid. The case now described seems to fall into this last group; in it gastritis and ulceration have apparently added to the pyloric disturbance and increased the symptomatic significance of the anatomical deformity. These factors, acting reflexly on the pylorus, may have been sufficient to upset the balance of the mechanism of the transference of contents between the stomach and duodenum, and so be responsible for the onset of gastric symptoms. It is not proposed here to analyse further the causation of the pain, but merely to indicate sufficient cause for its pyloric origin after many years of latency.

FIG. 1



A and B, cut ends of hypertrophic pylorus. C and D, sites of the ulcer.

FIG. 2



Microscopical section showing hypertrophy of the circular muscle-fibres stopping sharply at commencement of duodenum.

It is interesting to speculate on the similarity of the possible source of origin of symptoms in the congenital and adult cases. In the former, symptoms commence only after a latent period of some ten days or more, thus allowing for the development of gastritis on a deformity already present at birth. So, in the latter, it is suggested that the onset of gastritis was at the root of the commencement of symptoms, only after a latent period of many years. The end-result is not always necessarily pyloric obstruction, as has been stressed by previous writers and is exemplified by the case here described.

The alternative hypothesis is that the muscular hypertrophy is acquired. Chronic gastric ulceration, as in this case, situated well away from the pylorus, can hardly be incriminated for such a degree of hypertrophy; and when juxtapyloric ulceration causes stenosis and gastric dilatation, local muscular hypertrophy is never an observable feature. So far as I am aware no corresponding muscular hypertrophy has been described in other sphincters of the alimentary tract, nor is there any evidence to justify the assumption that chronic spasm may cause muscular hypertrophy. I cannot find any evidence to support Maier's contention of abnormal fixation of the pylorus as a possible ætiological factor.

A clinical review of the recorded cases shows the importance of eliciting a history of gastric disturbance in infancy. Symptoms may commence in early adolescence and middle age, and are those of recurrent indigestion suggestive of chronic ulcer, whilst some may be typical of a dilated stomach. No abdominal tumour could be palpated in any of the cases, but tenderness over the pylorus is common. A barium meal is important, and shows spasticity or a persistent filling defect of the pylorus; but the duodenal cap remains normal and an ulcer niche is never seen in the neighbourhood. There may be gastric delay this routine calcium treatment should be carried out on all ulcer cases in the hospitals and sub-dispensaries under his control; for many valuable suggestions, and for his assistance in the production of this paper.

My thanks are also due to Major G. J. Keane, director of medical and sanitary services, Uganda, for permission to publish this paper.

HYPERTROPHIC PYLORIC STENOSIS IN ADULTS

By Mark Coleman, M.S. Lond., F.R.C.S. Eng.

ASSISTANT IN THE SURGICAL UNIT, UNIVERSITY COLLEGE HOSPITAL

This condition has received scant recognition in England. On the continent attention was first directed to its possibility by Landerer in 1879; whilst in England, in 1904, Mayo-Robson and Moynihan described two cases. Since then a few isolated authentic cases have been reported in America, and Walton,[1] in his text-book of "Surgical Dyspepsias," remarks on two cases of his own. The following case possessed a complication not present in those so far described.

CASE RECORD

History.—The patient was a married man, aged 38, a platelayer, and he complained of periodical attacks of abdominal pain for seven years, with vomiting for the last two years. During the earlier years of this period upper abdominal pain came on regularly two to two and a half hours after meals. The periods of freedom from pain were as long as six months, but they had become progressively shorter, and the pain had increased in severity so that his appetite was affected. Eventually the pain became almost continuous; it was a dull gnawing ache, but became more acute within five minutes after a meal and induced belching and vomiting, which to some extent relieved it. Recently he has had typical "hunger pains" relieved by taking food or a bismuth mixture.

There was no history of hæmatemesis or evidence suggestive of melæna. Recollection of any gastro-intestinal disturbance in infancy was hazy and indefinite; 18 months before he had been investigated for supposed duodenal ulcer, and screening had shown suggestive evidence of a chronic ulcer low down on the lesser curvature with a tendency to spasm near the pylorus. It was considered that most of his symptoms were due to alcoholic gastritis, but strict dieting and abstinence from alcohol failed to ameliorate them.

Examination.—The patient was pale and thin and had a normal temperature. His teeth were mostly in good condition, except for slight pyorrhœa in the upper and lower incisors. The chest was long and thin and the epigastric angle narrow. No abdominal tumour was palpable, but there was a point of deep tenderness just to the right of the mid-line, a third of the way up between the umbilicus and the epigastric notch. No scars of previous laparotomy were present. There were no other physical signs. The test for occult blood in the stools was negative, as was also the van den Bergh reaction in the blood. The blood count was within normal limits. A fractional test-meal showed a small quantity of resting juice, absence of free HCl, a low total acidity, and fairly free regurgitation of bile. A barium meal showed a low hypotonic stomach with persistent contracture of the greater curvature near the pylorus. There was no deformity of the duodenal cap or delay in emptying of the stomach. No ulcer niche was seen, but the spasm was thought to be due to a pyloric ulcer.

Operation.—Mr. A. J. Gardham operated on Nov. 27th, 1931, and found a firm elastic mass surrounding the pylorus, ending abruptly on the duodenal side but gradually thinning and extending for some 1½ inches on the stomach side. The peritoneal surface was smooth and free from any evidence of inflammatory or neoplastic disturbances. Two small soft lymph glands were palpable in the subpyloric region. On the anterior surface of the stomach near the lesser curvature and 3 inches from the pylorus the stomach wall was thickened and œdematous, and the peritoneum greyish-white, with punctate hæmorrhagic speckling; the lesser omentum opposite this region was thickened. The stomach was not dilated. Gastrectomy and anterior gastro-jejunostomy (using the Balfour modification of Polya's operation) was performed. The patient made a rapid recovery, and at the time of writing is completely relieved of symptoms.

Specimen.—The resemblance of the pylorus projecting into the duodenum to the cervix uteri projecting into the vagina was marked, but the orifice was circular and patent. The tip of the little finger, when pushed through this opening from the pyloric side, was gripped by what felt like a ring of unyielding tissue; there was no grating on cutting the pylorus. The cut surface showed the tumour at the pyloric ring to be due to a muscular hypertrophy fully half an inch thick, stopping sharply at the duodenum but fading gradually into normal thickness of muscularis on the stomach side. The mucosa showed a moderate degree of chronic gastritis, but was freely mobile over the muscularis in the region of the pylorus. The puckered scars of healed chronic gastric ulcers corresponded in position to the external appearances observed on the stomach. Fig. 1 shows the muscular hypertrophy clearly and the healed ulcers in the top right-hand corner.

Microscopical section (Fig. 2) showed very great hypertrophy of the circular muscle-fibres, stopping sharply at the commencement of the duodenum, as indicated by the presence of Brunner's glands. The same region was also demarcated by the longitudinal fibres of the stomach turning up towards the mucosa, and conceivably acting as a sphincter to the pylorus in this region. There was an increase of interstitial tissue between bundles of muscle-fibres, consisting mainly of compressed fibrous tissue and looser fibres mingled with cells which were endothelial in type; but there was no inflammatory exudate. The mucosa showed the changes of gastritis, and there was considerable lymphoid tissue in the submucosa and diffuse infiltration with chronic inflammatory cells, but no suspicion of malignancy.

COMMENT

Landerer regarded pyloric stenosis in adults without hypertrophy or dilatation of the stomach as a congenital deformity. Maier[2] in 1885 added 21 further cases, most of which came to post-mortem examination on account of non-gastric diseases. The gastric clinical histories, when known, are very sketchily described; but he recorded two young adults who had complained of abdominal pain since early youth, and several others with histories extending over many years. He concluded that there exist pure cases of round or slit-like congenital narrowing of the pylorus. These may be complicated by a congenital muscular hypertrophy or catarrh of the stomach; some are also combined with either a congenital or a very early acquired abnormal fixation of the pylorus, due to an extraordinarily thick ligamentum hepaticum duodenale and gastro-hepatic omentum.

Mayo-Robson and Moynihan[3] in 1904 described two cases: in the first, a child aged 11 years, who had suffered from infancy with general abdominal disorders and vomiting, laparotomy showed a muscular hypertrophy of the pylorus; in the second, aged 24 years, with five years' duration of symptoms, operation revealed a contracted pylorus without any evidence of organic disease. They considered that these conditions might explain dilatation and catarrh of the stomach in young adults, or the persistent vomiting usually labelled "hysteria" or "pernicious habit."

Maylard[4] mentioned 15 cases which showed at operation a dilated stomach without muscular hypertrophy, ulceration, or neoplasm, but a uniformly narrowed pyloric aperture (between 2 and 12 mm. in diameter), just admitting the tip of a finger. The interior of the stomach was inspected by direct vision in all these cases, and gastro-enterostomy completely relieved all symptoms. He thought his cases congenital in origin, but was careful to emphasise that they were in no way akin to hypertrophic pylorus stenosis, although he considered that the latter condition probably existed in adults.

those included in these series intravenous treatment was found to be impossible on account of technical difficulties. The veins of small children are not always easy to negotiate, and in severe cases of all ages the veins collapsed very readily, especially as the disease advanced. One patient, a boy of 8, was given intravenous injections with ease on the fourth day of disease; on the fifth, it was quite impossible to get into any vein and on the sixth he died. In many cases, when the needle had entered the vein, the slightest pressure from the syringe caused exudation into the surrounding tissues. Experience in the treatment of malignant diphtheria shows that continued intravenous medication is difficult and frequently impossible. Emphasis must be laid on this point.

TABLE II

—	Total cases.	Fatal cases.				Recovered cases.			
		Total.	Fatality-rate.	Developed paralysis.	Paralysis-rate.	Total.	Recovery-rate.	Developed paralysis.	Paralysis-rate.
G.I.A.	25	17	% 68	5	% 29·4	8	% 32	7	% 87·5
A.T.	11	9	81·9	3	33·3	2	18·18	2	100

G.I.A. = Cases treated with glucose, insulin, and antitoxin.
A.T. = Cases treated with intramuscular and intravenous antitoxin.

Blood-sugar was not estimated as a routine. In 11 of the 25 cases of the glucose-insulin series the fasting blood-sugar was estimated once by the method of Folin and Wu. A reading outside normal limits was never found, even when the sample was taken—as in one case—two hours before death on the fifth day of disease. This does not seem to bear out the finding of other workers that there is usually an initial hyperglycæmia in the malignant cases. Anything in the nature of a routine tolerance test was considered to be out of the question. Veins, if not collapsed, were far too precious to be used for this purpose, and usually the patients were too ill to be upset by more needle insertions than were absolutely necessary. Several attempts were made to use the alternative method of Crecelius and Seifert,[5] but even here there was such difficulty in obtaining enough blood from an ear or finger that the attempt was abandoned.

The results of so small a number of cases as 25 can have no statistical value; one can merely gain impressions from them. The death of a patient from severe toxic diphtheria is often preceded by extreme discomfort and distress. One certainly gets the impression that, after treatment with glucose and insulin, this discomfort and distress (even in patients who succumb rapidly) are relieved. The relief is often so marked that in the short period before death the patient's friends find it difficult to believe that he is dying and not steadily improving. The treatment is perhaps worth while from this point of view alone. There are in diphtheria roughly two danger periods. Patients who succumb during the first period usually die within the first fortnight. Those who pass through the first period may survive or may live one or two months—an average of about six weeks—only to die after the development of multiple paralysis. In a series of 69 fatal cases occurring in 1931, not treated by glucose and insulin, only 18·8 per cent. survived to the second danger period. One is therefore encouraged to investigate further an auxiliary line of treatment by means of which 10 out of 25 apparently hopeless cases, or 40 per cent., survive to the second danger period, and 8, or 32 per cent., recover.

I am indebted to Dr. J. S. Anderson, superintendent of the Leeds City Hospitals, for his advice and for permission to publish these cases.

Clinical and Laboratory Notes

HÆMOLYTIC ANÆMIA

BY CYRIL G. EASTWOOD, B.SC., M.B. MANCH.
FORMERLY HOUSE PHYSICIAN, MANCHESTER ROYAL INFIRMARY

AND

GEORGE G. E. SMYTH, M.B. MANCH.
HOUSE PHYSICIAN AT THE INFIRMARY

(From the Department of Clinical Investigations and Research, Manchester University and Royal Infirmary)

A SINGLE woman, aged 23, a café manageress, was admitted to the Manchester Royal Infirmary on *April 14th, 1931.* She complained of attacks of vomiting and palpitation coming on every few weeks and lasting several days at a time.

In 1928 (three years before admission) she had been employed in a dye works. At this time she was set to work with a new yellow dye (whose constituents we are unable to ascertain), but she very soon developed anæmia and was away from work for six months. When she returned to work she was not completely well but felt "run down" and became easily tired. In 1930 she had an attack of jaundice which lasted for 16 weeks, and on returning to work she was again not completely well but lacked energy and felt "out of sorts." She had felt like this ever since.

In 1931 (some months before admission) she began to have attacks of vomiting. These attacks occurred at intervals of several weeks, and lasted for two or three days at a time; the vomit was bile-stained.

The appetite was poor and the bowels constipated, the stools usually being dark-coloured. Menstruation was regular, but the duration of the period had diminished from ten to three days. There were no urinary symptoms or œdema, but she had dyspnœa and palpitation on slight exertion.

Clinical examination.—The patient was pale and slightly yellow. Tongue, teeth, and fauces showed no abnormality. Systolic and diastolic murmurs were heard all over the præcordium, loudest over the mid-sternum; there was no cardiac enlargement. The lungs and abdomen were normal; the liver and spleen were not palpable. The central nervous system was normal. The Wassermann reaction was negative. Hæmolysis of red cells began in 0·46 per cent. saline, and was complete in 0·28 per cent. saline. The blood count showed:—

Red cells	960,000	Polymorph.	54·75 %
White cells ..	3,000	Lymphocytes ..	42 %
Hæmoglobin ..	20 %	Large mononucl...	3·25 %
Colour-index ..	1·05	Eosinophils	None.
Reticulocytes ..	44 %	Basophils	None.

Punctate basophils numerous; marked anisocytosis and poikilocytosis. Abundant platelets.

Progress.—On admission, on *April 14th*, the pallor and yellow colour suggested pernicious anæmia, although the blood film was not typical of this condition. A fortnight later the blood count was lower and the blood picture did

Except when complicated by gastric ulceration—and this would appear to be quite uncommon—the occult-blood test is negative; little help can be expected from a fractional test-meal.

Gastro-enterostomy or gastrectomy, when there is doubt as to the cause, is rational and successful treatment. In two cases pyloridosis was performed, and a second operation was necessary on account of recurrence of symptoms. Pyloroplasty or Finney's operation must be difficult in the presence of so much thickening and loss of flexibility of the pylorus.

I am indebted to Prof. C. C. Choyce for permission to publish this case and for much help and advice, and also to Mr. Julian Taylor for the record of his case.

MALIGNANT DIPHTHERIA

TREATMENT WITH GLUCOSE AND INSULIN

BY HESTER E. DE C. WOODCOCK,
M.B. LEEDS, D.P.H.
SENIOR ASSISTANT MEDICAL OFFICER, LEEDS CITY HOSPITALS

THE death-rate from diphtheria in Leeds has steadily risen from 0·04 per 1000 inhabitants in 1928 to 0·19 in 1931. The number of cases admitted to the *Leeds City Hospital for Infectious Diseases* has increased from 600 in 1928 to 984 in 1931. The type of disease has become much more severe, with a rise in case-mortality from 3·05 per cent. to 8·4 per cent. With increase in severity in type there has been a more than corresponding increase in the dosage of antitoxin, and, as the treatment has been largely in the hands of the same medical staff, the variable factor of personal judgment has to some extent been eliminated. Results of treatment with large doses of antitoxin, even if administered in the early stages of the disease, have often been disappointing.

One patient, for instance, who developed diphtheria in a scarlet fever ward, was given in all 160,000 units of antitoxin. Of these, 120,000 units were given within 12 hours of the first symptom, 100,000 being administered intravenously. Palate paralysis occurred on the fifth day and between the 27th and the 38th days there were four convulsive attacks with loss of consciousness for several hours and dilatation of the heart. The patient, a little girl of 6, eventually recovered after multiple paralysis and was discharged 16 weeks after the onset of the disease.

It was therefore decided to attempt an auxiliary line of treatment by giving intravenous glucose together with intramuscular insulin, as suggested by Schwentker and Noel[1] as a result of their researches into the disorders of carbohydrate metabolism occurring in diphtheria. During the last 18 months 28 cases of diphtheria have been treated by this method. Of these, 3 are not included in the series because they were not extremely severe. The other 25 cases would all have been classified as severe according to Bie's grouping,[2] and death was likely in every case. Many of the patients were extremely toxic, showing either delirium and excitement or drowsiness, amounting at times to unconsciousness. There were six hæmorrhagic cases. The youngest patient was 2 years old, the oldest 32. The average age was 10·8 years. The duration of disease before admission was 1–5 days, with an average of 3·4 days.

The routine treatment was as follows. On admission, 20,000 units of antitoxin were given intramuscularly. Two or three hours later 20–40 c.cm. of a 50 per cent. solution of glucose in distilled water were given intravenously together with 20,000–40,000 *units of antitoxin intravenously and* 10–20 units of insulin intramuscularly. This treatment was followed by daily doses of intravenous or intramuscular antitoxin until the membrane began to clear, or at any rate ceased to spread. The largest total dosage of antitoxin was 120,000 units. In the first few cases a second dose of glucose was only given occasionally, but in all the later cases, following on the results of the Birmingham workers,[3] the glucose has been repeated daily, the largest number of intravenous injections given in any one case being nine. Each was, of course, accompanied by insulin.

Attempts were made to give glucose by mouth (for instance, in the form of sweetened lemon water), but many of the patients rejected it and appeared to have an absolute distaste for anything sweet.

RESULTS

Among the first 14 cases treated, up to the end of 1931, there were only 2 recoveries (14·2 per cent.), but of the next 11 cases 6 survived (54·5 per cent.), giving a recovery-rate among 25 cases of 32 per cent. Age is, of course, an important factor in diphtheria and, as one would expect, the older patients responded better to the glucose treatment than did the younger ones (cf. Table I.). Of the 8 surviving cases, 7, or 87·5 per cent., developed paralysis, usually multiple. In the 1 surviving patient who did not develop paralysis, it is significant that the bacillus was of the *mitis* type.[4] It was possible to type 16 other cases (of which 11 were fatal), but in each of these the organism was of the *gravis* type. Of the 17 fatal cases, 5 only, or 29·4 per cent., lived long enough to develop paralysis; 3 of these had palate paralysis on the sixth, seventh, and eighth days, and died on the 13th, 14th, and 10th days respectively. One patient died on the 49th day and one on the 53rd, both with multiple paralysis. The average day of disease on which death occurred among all glucose-treated cases was the 12th or, if the two long cases above mentioned be set aside, the seventh. The earliest day of disease on which any case proved fatal was the second.

TABLE I

—	Cases.	Age in years.		
		Youngest.	Oldest.	Average.
All fatal cases of diphtheria, 1931	82	2	47	6·8
All glucose-treated cases ..	25	2	32	10·8
Fatal " " " ..	17	2	16	7·6
Recovered " " ..	8	4	32	17·25

During the period under review a small series of severe cases was treated with antitoxin alone, intravenously and intramuscularly. The largest total amount of antitoxin given was 160,000 units, of which 100,000 units were given intravenously. Of these cases the most severe, 11 in number, were comparable in type with those selected for glucose and insulin treatment. Table II. shows a comparison of the results of the two series. In many cases as severe as of purulent fluid in the pouch of Douglas, and numerous small diverticula of the large gut from the cæcum to the sigmoid flexure. The pouches were mainly thin-walled sacs, the gut wall being unthickened except in the descending colon, where some reactionary thickening had occurred. The stomach was adherent to the liver and, on attempting to separate adhesions, pus and black necrotic tissue exuded from a large abscess cavity the size of a fœtal head occupying the lesser sac. The foramen of Winslow was closed by adhesions. The tail of the pancreas was completely destroyed and replaced by dark hæmorrhagic necrotic tissue. The surrounding omentum and mesentery showed fat necrosis. The spleen, left kidney, and splenic flexure formed the left border of the abscess cavity. The splenic vessels were lying free in the pool of pus, but showed no signs of erosion. The splenic flexure showed four diverticula, one of which had perforated. A probe could be passed through the opening into the abscess cavity. The common bile-duct was dilated but patent; the gall-bladder was nearly empty, containing only a few drachms of "white bile."

The sequence of events appears to have been: perforation of diverticulum of splenic flexure into the lesser sac with the formation of an abscess and a final acute hæmorrhagic pancreatitis. Pressure of the abscess upon the common bile-duct had caused the original jaundice. The ante-mortem diagnosis was non-committal during the short time possible for observation and investigation. The character of the pain and jaundice were in favour of a gall-bladder condition: ? inflammatory, ?. neoplastic. The physical signs resembled those of carcinoma ventriculi with secondary deposits in the left chest.

CASE 2.—A married woman, aged 66 years, was admitted on April 15th, 1932, with the following note:—

"Became acutely ill 14 days ago with what was apparently cholecystitis. The attack subsided, but she has acute pain in the left loin which shoots into the perineum. Temp., pulse, and respiration normal. Nausea and constipation noted."

On admission she complained of pain starting from the interscapular region and radiating down the right side to the groin and leg; also of vomiting, at uncertain intervals, a greenish vomitus. She gave a history of jaundice in 1915 preceded by attacks similar to the present one. Constipation was admitted and recently the stools had been pale.

On *examination* her temperature, pulse, and respiration were normal, and her tongue furred and dry. She was an obese woman, and no definite physical signs were obtained beyond tenderness in the right subcostal region. The urine was normal in all respects (it contained no bile-salts or pigment). Her condition remained the same until the night of April 17th, when she had a definite rigor, the temperature rising to 102° F. for a brief period. On the following day the pains were worse. Ill-defined jaundice was noticed, most marked in the sclera. On April 19th she had complete suppression of urine, which persisted in spite of treatment until her death on April 21st. The temperature remained subnormal throughout, apart from the rigor.

Post-mortem examination (*Dr. Rickword Lane*).—An abscess starting in the tail of the pancreas immediately posterior to the splenic flexure of the colon tracked along the inferior surface of the pancreas as far as the neck. The pancreas was involved to the depth of the splenic vessels. The head of the pancreas was inflamed and necrotic in patches. Some fat necrosis was present, but in small areas only. The porta hepatis was cut off by adhesions and was full of greenish pus. A well-marked caudate lobe was covered with thick green pus. The gall-bladder was thickened and contracted and the cystic duct very much enlarged, as was also the common bile-duct, so that a finger could be passed from the gall-bladder to the duodenum with ease. The liver showed the abscess tracking along the portal entry vessels, and large septic infarcts were distributed throughout the organ. Minute embolic abscesses were found in the right lung, both kidneys (which were otherwise normal), and visceral pericardium. There was an inflamed diverticulum in the region of the tail of the pancreas, but the actual track could not be followed.

Other organs showed the usual changes expected at the age of the patient, but were not significant.

The cases are of interest from two points of view: clinically, the syndrome of pain in the right hypochondrium and jaundice was misleading; pathologically, diverticulum is an unusual cause of acute pancreatitis and portal pyæmia. Acute pancreatitis is commonly associated with and is the result of infection in the gall-bladder. Infection of the pancreas as a result of perforation of a diverticulum must be excessively rare. Molesworth [1] describes a case of perforation of diverticulum of the duodenum giving rise to acute pancreatitis, but we have found no record in the literature of this condition arising in perforation of a diverticulum of the splenic flexure, in itself a rare event.

There are several cases on record [2] of suppurative pylephlebitis and portal pyæmia following suppuration of diverticula of the sigmoid colon, but not of the splenic flexure. In two cases only were found systemic metastatic abscesses.[3 4] It is of further interest to note that the splenic vein was not thrombosed in either case, although surrounded by pus.

We are indebted to Dr. Abrahams and Mr. Sydney Boyd for permission to publish these cases, and to Dr. Lane for the post-mortem reports.

THYROID ADMINISTRATION IN A DIABETIC WITH MILD HYPOTHYROIDISM

BY A. W. HENDRY, O.B.E., M.D. ABERD., M.R.C.P. LOND.
ASSISTANT PHYSICIAN, ABERDEEN ROYAL INFIRMARY

A WOMAN, aged 24, height 57½ in., weight 66 lb., was in 1925 admitted to Aberdeen Royal Infirmary. She suffered from fairly severe diabetes mellitus, and a moderate degree of exophthalmic goitre. In addition to thirst, glycosuria, wasting, and hyperglycæmia, there was exophthalmos, tachycardia, nervousness, and tremor.

A glucose-tolerance test was as follows:—

	Per cent.
Fasting blood-sugar	0·287
40 minutes after 50 g. glucose	0·306
80	0·366
120	0·441
180	0·416

She was treated for the diabetes: no special measures were instituted for the hyperthyroidism. Her diet consisted of seven "line-rations," and she had 10 units of insulin thrice daily. On this régime she remained sugar-free till September, 1926, when it was found necessary to increase her insulin to 13 units thrice daily. This increase rendered her sugar-free, and her weight increased to 98 lb. In May, 1927, the basal metabolic rate was +56 per cent., and the signs of hyperthyroidism had lessened. In August, 1927, she had an attack of diabetic coma, and there was another in August, 1930. After the latter attack she seemed to be balanced with seven line-rations, and 80 units of insulin per day. Her weight was now 112 lb.

She remained fairly well for a time, but in October, 1931, was admitted with still another attack of coma. She was very ill, and it was a considerable time before she came round. After recovery from the coma great difficulty was experienced in adjusting her diet and insulin. On eight line-rations diet she received 35 units of insulin thrice daily, and yet the urine contained a large amount of sugar and acetone On this régime the blood-sugar, two and a half hours after a meal, was 0·420 per cent. At this juncture several points forced themselves on the attention. In a small person eight line-rations ought to have been sufficient to keep her comfortable if the sugar were metabolised. Even if she had no capacity to use sugar 20 units should have been enough. Our patient was having eight line-rations and 108 units of insulin per day, and yet her blood-sugar was 0·462 per cent., with marked glycosuria and ketonuria. The insulin somehow was not functioning.

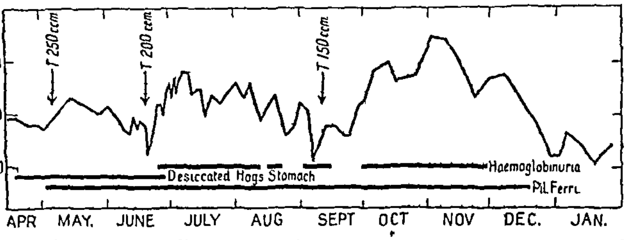
not resemble that seen in pernicious anæmia. The general condition was worse and the yellow colour more pronounced; four days later the patient had a blood transfusion of 250 c.cm. The blood count improved (see graph) and the general condition became better.

During the next six weeks the blood count gradually diminished, and on June 19th a second transfusion of 200 c.cm. was given. Immediately after the transfusion the blood count sank very low, but after four days it rose rapidly to over 1,000,000 (see graph), and at the same time hæmoglobinuria began. Radiography revealed no abnormality of the urinary tract, and cystoscopy showed blood-stained urine coming from each ureter. From the end of June until September the jaundice became gradually deeper and the patient weaker. The blood count fluctuated as shown on the graph, hæmoglobinuria being observed whenever the erythrocytes reached 1,000,000, and ceasing when they sank below 1,000,000. On Sept. 10th another transfusion of 150 c.cm. was given, and a fortnight later the blood count rose suddenly. As it passed 1,000,000 hæmoglobinuria returned.

At this time the skin was pigmented a dark bronze colour, but microscopical examination of a section did not reveal the nature of the pigment, which failed to stain with fuchsin, and gave no reaction for iron. The urine was a deep mahogany colour, and gave a strongly positive benzidine reaction, while the spectroscope showed the presence of oxyhæmoglobin. Microscopical examination showed no red cells in the urine, and tests for bile were negative.

At the beginning of December vomiting began and became increasingly frequent; hæmoglobinuria ceased and the temperature became irregular, fluctuating between 98·4° and 102° F. During the first week in January the jaundice became almost black and the urine deeply bile-stained. The patient, who until now had been very cheerful and intelligent, became mentally dull. At the end of January she sank into a stuporose condition, and the liver and spleen became palpable. On Feb. 3rd she died, and for some hours before, the liver (which had rapidly enlarged to below the umbilicus) pulsated visibly.

Post-mortem examination.—There was no enlargement of the heart, but fatty degeneration and "tabby cat" striation were seen, and the left ventricle was somewhat dilated. There was no other abnormality of the heart or pericardium. The lungs and pleuræ were normal except for an appearance of jaundice on the cut surface of the lungs. The gastric mucosa was a diffuse prussian blue colour, but otherwise normal. The duodenum was finely stippled all over with blue-black granules. The large intestine, peritoneum, and omentum were normal. The liver weighed 1750 g., and was bright brown in colour from gross deposits of hæmosiderin, which gave the prussian blue reaction. The centres of the lobules were pale and yellow. The gall-bladder and pancreas were normal, and the latter showed no pigmentation. The spleen, which weighed 270 g., was enlarged, fairly firm, and of normal colour. The thyroid was pale, and contained much yellowish colloid, which was very sticky and exuded from the cut surface. The kidneys were enlarged; the right weighed 250 g., and the left 220 g.; the cortex was wide and of a deep chocolate colour. The adrenals were rather small but otherwise normal. The genital glands and ducts were normal. The marrow in the shafts of the femurs was bright red, with fine spicules of bone throughout.



Graph showing the red cell count and its relation to treatment. T= blood *transfusion. The horizontal lines indicate the periods of hæmoglobinuria* and the periods during which the patient received desiccated hog's stomach and pil. ferri.

Microscopical examination of organs.—The centres of the lobules of the liver showed very advanced fatty degeneration. The cells in the portal tracts showed hæmosiderin, but not in such quantities as in the kidneys. The Küpffer cells were also filled with hæmosiderin. The endothelial cells throughout the spleen were *loaded with hæmosiderin.* The organ was congested but otherwise normal. The first convoluted tubules and descending limbs of Henle showed pigmentation of their epithelium. The pigment was in coarse brown granules about 2 μ in diameter. The mitochondral zone of the cells consisted of hæmosiderin. The adrenals showed no hæmosiderin. *All* the vesicles of the thyroid were very large and distended with homogeneous colloid. There was gross œdema of the lungs and hyperplasia of the bone-marrow, but the latter contained no hæmosiderin.

Similar cases have been reported in which great benefit was derived from splenectomy. This was considered in the present case, but could not be carried out owing to the poor general condition. Three blood transfusions were given in an attempt to prepare the patient for operation, but on each occasion she developed pyrexia and hæmoglobinuria. The occurrence of hæmoglobinuria is a feature for which we are quite unable to account, and post-mortem examination threw no light upon it.

We wish to thank Prof. A. Ramsbottom, under whose care the patient was, for permission to publish this case; also Prof. S. L. Baker, who placed the post-mortem notes at our disposal.

TWO UNUSUAL CASES OF DIVERTICULOSIS

By Anthony Caplan, M.B. Lond.
HOUSE PHYSICIAN, HAMPSTEAD GENERAL HOSPITAL
AND
Walter J. Tindall, M.B. Lond.
HOUSE SURGEON AT THE HOSPITAL

These cases are put on record as pathological curiosities, with the added interest of the coincidence that they were admitted to hospital at a comparatively short interval.

Case 1.—A married woman, aged 72, was admitted to the Hampstead General Hospital on March 28th, 1932, under the care of Dr. Adolphe Abrahams, complaining of feeling weak. She stated that she had been quite well until five weeks before, when she had experienced fairly acute pain in the right hypochondrium, accompanied by nausea. When seen by a doctor she had been found to be jaundiced, with a temperature of 100° F., and a pulse-rate of 80. The abdomen had been slightly rigid all over; the gall-bladder had been doubtfully palpable. No cyanosis had been noted. Her condition had improved, jaundice and pain disappearing, and after two weeks she had felt able to get up, whereupon the pain and jaundice had recurred. Later the jaundice had disappeared, but pain had persisted in the right hypochondrium, pyrexia also being present. The stools had been rather pale throughout the illness, and she had vomited soon after food during the last few days. She had suffered for three years from flatulence.

On *admission* she was cachectic, but had no obvious jaundice and no cyanosis. Her temperature was 102° F., her pulse-rate 130, and her respiration-rate 20. Her tongue was furred and dry. There were no palpable glands in the neck, and no enlargement of the heart. The sounds were normal. Her blood pressure was 132/80. The percussion note was dull at both bases and the air entry poor, especially at the left base. The breath sounds were vesicular. Crepitations were heard at both bases. The abdomen was *somewhat* distended generally. The upper part was rigid, and an indefinite mass was felt in the epigastrium. There was no evidence of free fluid. The urine was *acid* and had a specific gravity of 1020. It contained no albumin, sugar, or bile. A few hours after admission the patient had a rigor, collapsed *and died.*

Post-mortem examination (Dr. C. Rickword Lane).—Apart from a little clear fluid in the left pleural cavity and generalised fatty changes in the viscera, the only pathological findings were in the abdomen. There was a small collection

DISCUSSION

Sir **Charles Gordon-Watson** agreed about the importance of preliminary colostomy, and also supported Dr. Coffey's method of quarantine drainage. The abdomino-perineal one-stage operation was not, he thought, an essential one for radical excision, and he believed that it was not called for in early cases, especially where the growth was below the peritoneal reflexion; also, it was a dangerous operation, except in the hands of the most expert. For growths at the recto-sigmoidal junction some form of two-stage abdominal operation was safer and wiser; and where the growth was high he considered it was neither necessary nor desirable to remove the rectal ampulla.

Mr. **Ernest Miles** said that Dr. Coffey's mortality figure of 6·25 per cent. for the two-stage operation was extraordinarily good. And he thought the method now described could scarcely be excelled. He personally had always lacked the courage to do a two-stage operation, for two reasons. The first was that the perineal portion of the operation took such a short time, provided the abdominal portion of the operation had been done, and he therefore hesitated to subject the patient to a second anæsthesia and operation to complete the removal. His other reason was that he had hesitated to lock up in the lower abdomen a portion of tissue which had been devascularised and which was thus liable to septic necrosis, for all rectal carcinomata were very septic. In his first series of abdomino-perineal cases the mortality was 33 per cent., but that had now been reduced to 7·6 per cent., and the reduction had been brought about by methods other than making it a two-stage operation—i.e., by a change in the anæsthetic and in a number of small details. In his early cases the anæsthetic used was open ether, and this resulted in a distinct lowering of the blood pressure, so that a number of his patients succumbed to the shock of the operation. The substitution of gas-and-oxygen and spinal anæsthesia with intrathecal stovaine at once reduced his mortality to 17 per cent. though the anæsthesia did not last longer than 45 minutes. He now used a caudal block with 2 per cent. novocain extrathecally, and this gave complete anæsthesia of the perineum for two or three hours. As a result of that, the mortality was reduced to 9·8 per cent.; and since he had made use of blood transfusion it had been 7·6 per cent. He was now using percaine, which gave anæsthesia for five or six hours.

No form of operation for cancer was of avail unless it could show a low recurrence-rate. Cancer of the tongue showed such a high recurrence-rate that surgical removal had now been abandoned for radium and diathermy. The most malignant cancers of the rectal region were the colloidal and melanotic, and it was likely in these that before operation could be done the disease had already spread beyond the confines of even the biggest operation. The papilliferous and adenocarcinoma showed a good freedom from recurrence. He agreed as to the great value of Dukes's classification, but no one could determine clinically that a case belonged to A, B, or C category.

Mr. **J. P. Lockhart-Mummery** said that the need was for an operation which would cure the largest number of cases with the least risk, and the one which did that best was the perineal operation, carried out in two stages. The difficulty was that it could not be done in cases of high growth. As the second stage which had been discussed did not occupy more than five minutes, he did not see the necessity of a second operation. In earlier days two-thirds of the cases were lost from sepsis, and surgeons in the last 20 years had been concentrating upon getting rid of this source of danger. He did not say sepsis was not now met with, but aseptic results were now being obtained in these cases. He liked to get the pelvis to heal up without drainage. Surely the mortality now reached in these operations should be considered to be low, bearing in mind that the patients' ages ranged from 55 to 70 years, when resistance was notoriously much lower than in life's full tide. The great need was to get cases of cancer of the rectum at an earlier stage than at present; this was apparently the only hope of reducing the mortality still further.

Mr. **W. Turner Warwick** spoke as one who for some time had used and advocated the Coffey two-stage operation. Using the perineal excision for low rectal and anal growths, and the two-stage operation for high growths, he maintained that the surgeon with an average amount of experience could deal satisfactorily with all operable cases of rectal cancer. He had operated upon 12 patients by the Coffey method without a death. For his own purposes he had made modifications in the procedure, one of which was to drain the subperitoneal space through a stab wound at the side of the coccyx, and another was always to cut the external sphincter, for that increased the comfort of the patient. One of the greatest advantages of the Coffey operation was that it enabled the pelvic diaphragm to be retained, and the patient was left a whole man.

Mr. **W. B. Gabriel** considered the Coffey operation particularly valuable for ampullary cancer. In the recto-sigmoid cancers there was the difficulty in invaginating the rectum where the fat must be trimmed off the bowel.

Dr. **Coffey**, in reply, said the advocates of the various operations were not really far apart from each other. Until he evolved the operation he had been describing he practised colostomy plus perineal resection. Resecting the growth of the rectum and preserving the sphincter could be done by an operator with the necessary judgment, but almost all the noted surgeons who had done that had subsequently abandoned it. There was a place and a kind of case for all the operations, and in choosing one of them the economic circumstances of the patient could not be altogether left out of account.

MEDICAL SOCIETY OF INDIVIDUAL PSYCHOLOGY

At a meeting of this society, held on Oct. 13th at 11, Chandos-street, London, W., with the President, Prof. **W. Langdon Brown**, in the chair, Dr. **Leonard Seif**, of Munich, read a paper entitled

The Individual and the Community

Dr. Seif said that the relation of the individual to the community is the central problem of individual psychology. Every science has an object. In individual psychology man is regarded as a human or fellow being. It inquires whether the expressions of any one person are those of a fellow man or of a counter man. Reality, as the framework of life, is closely connected with each of the aspects into which the task of life may be divided—namely, society, work, and sex. After discussing these questions, Dr. Seif passed on to consider the part played by the

In searching for cause or causes of this absence of insulin action, it was ascertained that her basal metabolic rate was now −7 per cent., whereas previously it had been above normal. Hyperthyroidism had gone, but there were no clinical signs of myxœdema. The increased weight was attributed to the diabetic treatment. My chief, Dr. Thomas Fraser, put her on thyroid (whole gland) gr. 1 per diem, and there was a dramatic change. Daily she suffered hypoglycæmic attacks. The blood-sugar, two and a half hours after a meal, was now 0·081 per cent. After an interval, during which the diet and insulin were adjusted, it was found that now, with this daily 1 g. of thyroid, she was sugar- and acetone-free on a nine line-ration diet, with 45 units of insulin per day.

During the last six months her condition has remained excellent on this treatment. She looks the picture of health. She goes about a lot and enjoys life. The urine throughout has always contained some sugar, but there has been no ketonuria.

These are the facts of the case. In a diabetic with slight hypothyroidism, insulin became inactive and without effect; when thyroid was given insulin activity manifested itself. In this case, it is considered, insulin activity was conditioned by the thyroid, because other factors in the case were not altered. The patient required increasingly large doses of insulin to maintain the desired therapeutic effects. This tolerance was markedly lessened by the presentation of a small dose of thyroid. The findings would lead one to suspect that insulin is not the only hormone necessary for the normal metabolism of sugar and fats—that insulin does not in all cases solve the whole problem in diabetes.

MEDICAL SOCIETIES

ROYAL SOCIETY OF MEDICINE

SECTION OF SURGERY, SUBSECTION OF PROCTOLOGY

AT a meeting of this subsection on Oct. 17th, with Mr. W. S. PERRIN, the President, in the chair, a discussion on the

Treatment of Cancer of the Rectum

was opened by Dr. R. C. COFFEY, of Portland, Oregon. In former days, he said, cancer of the rectum was placed on the borderline in regard to operability; but now it was conceded that of all parts of the body this region was the one which could best be devascularised and freed from cancer-ridden tissues. Nowhere was early operation more certain to bring about a cure, and in this respect cancer of the rectum was certainly more favourable than cancer of the breast. Most of the blood-supply to the rectum and sigmoid colon, and to the connective tissue and fat in the hollow of the pelvis came via the superior hæmorrhoidal artery, and most of the return was through the corresponding veins, accompanied by lymphatics, which constituted almost the sole avenue of spread of the disease upward. These vessels could be secured by a single ligature above the sigmoid, thus removing the danger of upward metastasis during the operation. Ernest Miles preferred the one-stage operation, but others, perhaps equally skilled, would get better results with the two-stage. Until there was new and contradictory knowledge of the nature and mode of spread of cancer, no vital change was possible in the one-stage operation of Miles, provided a one-stage was chosen.

Three types of two-stage operation had been devised in America: (1) the Mayo operation, which was used in this country at the same time by Lockhart-Mummery; (2) the Jones operation; and (3) the operation practised by the speaker. In the first part of his operation Dr. Coffey ligatured both internal iliac arteries, the sigmoid was severed, and colostomy was performed. The superior hæmorrhoidal artery was ligated at the promontory, and removal of glands and fat rendered the operation a very complete one; the fat was separated down to the tip of the coccyx, and not more than a couple of ounces of blood need be lost in the whole operation. When all the vessels had been dealt with, the intestine was severed through the clamps. At the lower end an aperture was left for the drainage, which he and his colleagues regarded as absolutely essential. The drainage of the retroperitoneal area or the connective tissue area involved a principle which did not apply to many parts of the body. The retroperitoneal or broad ligament area consisted of a mesh-like substance, which held fluids by capillary attraction, and the only successful drainage of that was capillary drainage; 12 to 36 small wicks were used to suck up the fluid in this area, and these were very effective. This drainage continued while granulation tissue was forming at the bottom of the wound, and the drains were left in situ for about a week.

The second stage of the operation, a week later, did not occupy more than five minutes, because there were no vessels to be dealt with. To leave the coccyx behind was to render the operation unsuccessful, and where it had been left, it was necessary to return and remove it; for here one had to deal with a large bony cavity which was non-collapsible in at least half its circumference, and so must heal by granulation.

In Dr. Coffey's experience recto-sigmoid cancer had a mortality of 23·6 per cent., as against the 6·5 per cent. in all the work he and his colleagues had been doing in the last 15 years by the inversion method. That difference was not due to the situation of the cancer; it was because in the case of the higher growths one was dealing with intestinal obstruction and the accompanying toxæmia. In those cases obstruction was usually the first symptom, and a large proportion of the patients would die of simple colostomy. Cæcostomy was also necessary.

Some surgeons advocated a "local" operation. This might be all right in the hands of the expert, but it was bad teaching, since many surgeons must lack the correct judgment as to what was best in a given case. In 1928 Dr. Coffey had had 152 cases; 24 were not operated upon, 49 were explored, and removal was carried out in 79. Statistics should never be taken as an absolute guide, for much depended on the manner in which they were compiled; at one stage of his work he had a low average mortality over a considerable number of cases, and then lost two out of three. Of 209 cases on which he had operated until 18 months ago, 47·8 per cent. were operable.

Dr. Coffey said he was now gradually coming to the three-stage operation, though he regarded Mr. Miles's dicta as gospel. In an advanced case one should first do colostomy and cæcostomy; the cæcum could be held up and the gas should be withdrawn with a trocar, enlarging the opening and inserting a mushroom catheter by Hendon's method; then sutures were put across it so that it could not be pulled out. Afterwards this was pulled up and the end was cut off. After doing colostomy and cæcostomy, the case could be dealt with as if it were one of cancer of the rectum alone.

pulmonary tuberculosis (primary) occur in early adult life chiefly ? (7) Does the bovine bacillus from long residence in human tissues become transmuted into the human type, and so produce lung infection ? (8) Does a bovine infection of the human body produce immunity against the human bacillus and vice versa ? (9) Does a reinfection ever occur in the human ? (10) Can tubercle bacilli in human tissues be destroyed ? (11) Is the infection ever antenatal ? (12) Is there any hereditary predisposition to infection ?

In conclusion, Dr. Raw strongly urged the appointment of a Government departmental commission to consider the best methods of dealing with and supplying milk to the public.

REVIEWS AND NOTICES OF BOOKS

Accidents, Neuroses, and Compensation

By James H. Huddleson, Associate in Neurology, Columbia University. With a Foreword by J. Ramsey Hunt, M.D., Sc.D. London: Baillière, Tindall and Cox. 1932. Pp. 256. 21s.

Opinions about traumatic neuroses range from the still surviving belief in physical trauma of the central nervous system to a condemnation of the sufferer as a malingerer. Dr. Huddleson, whilst avoiding this condemnation, has no doubt as to the part played by compensation in the maintenance of these disorders and urges that public opinion should be educated to awareness of its ultimate disadvantages. His study of the problem, involving citations of over 300 authorities, is thorough and bears the mark of an extensive personal experience. The introduction is devoted to the discussion of structual versus non-structural theories of the psychoneuroses, with the excursion into metaphysics to which such discussion of necessity leads. In the chapter on ætiologies the consideration of many opinions leads to the conclusion that "social sanctions increasingly attach responsibility for injury, monetary reparation, and recovery of health, to an individual or group other than the injured. With the growth of this tendency goes an enhanced incidence of traumatic neurosis, swelling demands for compensation, and more justifiable suspicions of exaggeration or malingering." Under the heads of classification and symptomatology the traumatic neuroses are considered without any hint of relationship to non-traumatic psychoneuroses—to those "nervous breakdowns," for example, which in the statesman or society lady are perfectly respectable. The result is unsatisfying to psychopathologists who take a wider view. The methods of treatment described range from torpillage—the surprise painful attack which cures; only to be permitted in times of military necessity—to the hypnotic treatment of amnesias, and there are useful warnings about the harmfulness of prolonged physical treatments. War material is freely drawn upon, and the author describes the difficulties in the restoration to psychoneurotic veterans of their self-reliance and sense of responsibility, difficulties largely due to continuous compensation. In a final chapter is summarised recent work in America and this country on the psychological side of accident prevention.

The book is likely to rouse opposition, but anyone familiar with industrial cases must admit that compensation for psychoneuroses has greatly increased their duration and incidence. The advocacy of no compensation, or a small lump sum made absolutely final, with energetic treatment and speedy replacement at work, stands in contrast to the common attitude, not always limited to the patient and his friends, that the neurosis is an exogenous infliction for which the injury is entirely responsible and for which the only remedy is ample compensation. A difficulty, in this country at least, is that there are few facilities for that treatment without which the psychoneurotic workman may be compelled to cling to compensation as his only hope. The consideration of Dr. Huddleson's proposals calls for a wider knowledge of the psychoneuroses than exists at present, but with that caution the book is recommended as a vigorous presentation of an important subject.

Urology in Women

By E. Catherine Lewis, M.S. Lond., F.R.C.S. Eng., Surgeon to the Royal Free Hospital; Surgeon and Urologist to the South London Hospital for Women. London: Baillière, Tindall and Cox. 1932. Pp. 76. 6s.

In this book the emphasis laid on urological conditions found in female patients should be very useful, especially to those whose experience of urology has been mainly confined to the male sex. Miss Lewis has had ample opportunity, as surgeon to the Royal Free Hospital and urologist to the South London Hospital for Women, of accumulating special experience of genito-urinary conditions peculiar to women, and has here placed the fruits of this experience at the disposal of the profession. The differences between the anatomy of the lower urinary tract in men and women render each liable to certain lesions which do not appear in the opposite sex, and it is with these that Miss Lewis deals rather than with diseases common to both. The section on the bladder is particularly helpful, since chronic cystitis is one of the commonest and most difficult conditions to combat amongst female maladies. We regret that she has not included in this chapter functional conditions, particularly functional frequency and enuresis. Another omission which we would like to see remedied in a future edition is nephroptosis, which is a condition found far more frequently in the female than in the male.

The work is well illustrated, the text clear, and the handling of the subject matter practical. This little book should certainly make and keep a place for itself in urological literature.

Principles of Preoperative and Postoperative Treatment

By Reginald A. Cutting, M.D., C.M., Assistant Professor of Surgery, Louisiana State University Medical Centre. New York: Paul B. Hoeber, Inc. p. 812. $10.

This book is both a work of reference upon recent advances in applied physiology and biochemistry, and a practical manual of pre- and post-operative treatment. Dr. Cutting possesses the qualifications essential to the writer of a good medical book: a wide and accurate knowledge of scientific literature, sound critical common sense, and a scholarly and lucid style. All recent investigations of real importance are discussed and explained in this volume, and in every case an attempt is made to assess the value of methods of treatment, while the author is careful to recommend no procedure which does not rest upon a sound basis, and which has not been adequately

absolute helplessness of the infant in developing the inborn tendency to overcome its "burning sense of inferiority." As growth and accomplishment reduce the gulf between the child and its surroundings, so do personal and egotistic interests tend to decrease; in this way some harmony between personal and social interests is made possible. He touched upon the factors which influence this development, and the rôle of the mother in promoting an atmosphere favourable to the production of courage and self-confidence.

The two words, courage and the community, he said, are characteristic of individual psychology. Courage is especially important, for without it true community feeling is not possible. As a viewpoint for distinguishing between different individuals, courage is better than intelligence, æsthetics, or morals. The intelligence of the courageous individual is quite different from that of the anxious or frightened person who tends to ask "What do people think of me?" "Do I like people?" and so on. This egotistic standpoint is especially apt to occur where an organ inferiority is present, or where the parents have misunderstood the child and have treated him wrongly. Both spoiling and snubbing foster excessive self-feeling. In the one case the children want what they feel to be their right, in the other they want what they have never had.

Dr. Seif indicated the ways in which confidence furthers a healthy relationship between the individual and the community, whereas a sense of deficiency is associated with the occurrence of neurotic, psychotic, or criminal tendencies. He regarded it as the aim of individual psychology to increase the courage and confidence of those with whom it deals, and so to create a more liveable world.

DISCUSSION

Dr. T. **LAWSON** said that Dr. Seif had spoken of the distance of the child from its environment and the duty of the parents to teach the child its social relationship, and asked whether the community feeling was latent or had to be taught.

Dr. F. G. **CROOKSHANK** spoke of the significance of the inferiority feeling upon which Dr. Seif had laid stress. He illustrated the interdependence of the individual and the community by an asylum story, in which the attendant, at the end of an observation which he had made as to the possible recovery of one of the patients, remarked "You may take it from me, Sir, a lunatic never has no friends."

Dr. O. H. **WOODCOCK** was interested in the way in which Dr. Seif had dealt with the rising generation, and with its need to learn to meet the world. He spoke of the value of the community feeling as taught by individual psychology, and suggested that the secret for the salvation of civilisation might be found here.

Dr. **JAMES YOUNG** agreed with the emphasis laid on the importance of the attitude of the individual to life. He observed that Dr. Seif had shown the philosophic or humane background of individual psychology.

Prof. **LANGDON BROWN** asked whether a neurotic could be a lady or a gentleman, since he was always trying to take more out of the common stock than he put in. He spoke of the responsibility of parenthood in giving some sense of security. The removal of the sense of insecurity found in so many patients was more important than growing cultures from their excretions.

Dr. **SEIF**, in reply, said that social feeling was inborn. In the course of his treatment the individual learnt to become what he really was, but had not had the chance to develop. The neurotic wished to give the appearance of coöperation. Sugar was more nourishing than saccharine, but the latter was many times sweeter. Individual psychology was one of the best foundations for a sound sociology. True love was associated with self-reliance and coöperation.

HUNTERIAN SOCIETY

ON Oct. 17th, at the first meeting of the session, Dr. **NATHAN RAW** delivered a presidential address entitled

Human and Bovine Tuberculosis

About 8 per cent. of samples of milk delivered into the large towns in England contained living tubercle bacilli, he said, while the deaths from tuberculosis in children up to 10 years of age were estimated at about 3000 per annum in Great Britain. This, however, did not represent the enormous amount of permanent crippling and deformity in those who had survived an attack. The eradication of tuberculosis from dairy cows was undoubtedly one of the most serious problems of the day, and the only real solution was to prevent the infection of calves. As early as 1906 Dr. Raw came to the conclusion that good results could not be obtained by the use of virulent cultures; accordingly, he secured pure cultures of the three strains of the tubercle bacilli and commenced the attempt to attenuate these by repeated subculture. Until the eighty-fourth generation of the culture no change in the virulence was noticeable. After that time, however, attenuation became marked, and the result of a long series of experiments had been the conclusion: (1) that it is possible to render the tubercle bacillus non-pathogenic; (2) that a vaccine prepared from this avirulent organism has enhanced immunising properties and can be used with perfect safety in large doses. The method adopted was the injection of cultures of human bacilli grown in the laboratory for 23 years, which were non-pathogenic and avirulent. So far, between 6000 and 7000 calves, chiefly of pedigree stock, had been immunised. The vaccine was injected when the calf was a week old, and again at the end of two weeks; and very satisfactory results had been obtained. He also used 23-year cultures in the treatment of human tuberculosis, again with very satisfactory results. They caused no reactions, no increase of pulse-rate, and no general disturbance.

Dr. Raw then discussed the question of mutation. Is it possible, he asked, that the bovine bacillus when introduced into the human body in children may lie dormant in the tissues for many years, and becoming adapted to its new environment, may assume the characteristics of a human bacillus, and thus set up human tuberculosis? It was certainly very difficult to explain why the bovine bacillus should almost invariably attack children, and why the human bacillus should so frequently attack the lungs between the ages of 18 and 25. These were questions of immense importance, and he put forward a few problems which awaited solution. Thus: (1) What is the life history of the T.B. before it enters living tissues? (2) Has it undergone a previous mutation? (3) Is infection of the lungs respiratory or alimentary? (4) Does direct respiratory infection from person to person occur? (5) Why do bovine infections in the human occur in childhood chiefly? (6) Why does

pulmonary tuberculosis (primary) occur in early adult life chiefly? (7) Does the bovine bacillus from long residence in human tissues become transmuted into the human type, and so produce lung infection? (8) Does a bovine infection of the human body produce immunity against the human bacillus and vice versa? (9) Does a reinfection ever occur in the human? (10) Can tubercle bacilli in human tissues be destroyed? (11) Is the infection ever antenatal? (12) Is there any hereditary predisposition to infection?

In conclusion, Dr. Raw strongly urged the appointment of a Government departmental commission to consider the best methods of dealing with and supplying milk to the public.

REVIEWS AND NOTICES OF BOOKS

Accidents, Neuroses, and Compensation

By JAMES H. HUDDLESON, Associate in Neurology, Columbia University. With a Foreword by J. RAMSEY HUNT, M.D., Sc.D. London: Baillière, Tindall and Cox. 1932. *Pp.* 256. 21*s.*

OPINIONS about traumatic neuroses range from the still surviving belief in physical trauma of the central nervous system to a condemnation of the sufferer as a malingerer. Dr. Huddleson, whilst avoiding this condemnation, has no doubt as to the part played by compensation in the maintenance of these disorders and urges that public opinion should be educated to awareness of its ultimate disadvantages. His study of the problem, involving citations of over 300 authorities, is thorough and bears the mark of an extensive personal experience. The introduction is devoted to the discussion of structual versus non-structural theories of the psychoneuroses, with the excursion into metaphysics to which such discussion of necessity leads. In the chapter on ætiologies the consideration of many opinions leads to the conclusion that "social sanctions increasingly attach responsibility for injury, monetary reparation, and recovery of health, to an individual or group other than the injured. With the growth of this tendency goes an enhanced incidence of traumatic neurosis, swelling demands for compensation, and more justifiable suspicions of exaggeration or malingering." Under the heads of classification and symptomatology the traumatic neuroses are considered without any hint of relationship to non-traumatic psychoneuroses—to those "nervous breakdowns," for example, which in the statesman or society lady are perfectly respectable. The result is unsatisfying to psychopathologists who take a wider view. The methods of treatment described range from torpillage—the surprise painful attack which cures; only to be permitted in times of military necessity—to the hypnotic treatment of amnesias, and there are useful warnings about the harmfulness of prolonged physical treatments. War material is freely drawn upon, and the author describes the difficulties in the restoration to psychoneurotic veterans of their self-reliance and sense of responsibility, difficulties largely due to continuous compensation. In a final chapter is summarised recent work in America and this country on the psychological side of accident prevention.

The book is likely to rouse opposition, but anyone familiar with industrial cases must admit that compensation for psychoneuroses has greatly increased their duration and incidence. The advocacy of no compensation, or a small lump sum made absolutely final, with energetic treatment and speedy replacement at work, stands in contrast to the common attitude, not always limited to the patient and his friends, that the neurosis is an exogenous infliction for which the injury is entirely responsible and for which the only remedy is ample compensation. A difficulty, in this country at least, is that there are few facilities for that treatment without which the psychoneurotic workman may be compelled to cling to compensation as his only hope. The consideration of Dr. Huddleson's proposals calls for a wider knowledge of the psychoneuroses than exists at present, but with that caution the book is recommended as a vigorous presentation of an important subject.

Urology in Women

By E. CATHERINE LEWIS, M.S. Lond., F.R.C.S. Eng., Surgeon to the Royal Free Hospital; Surgeon and Urologist to the South London Hospital for Women. London: Baillière, Tindall and Cox. 1932. *Pp.* 76. 6*s.*

IN this book the emphasis laid on urological conditions found in female patients should be very useful, especially to those whose experience of urology has been mainly confined to the male sex. Miss Lewis has had ample opportunity, as surgeon to the Royal Free Hospital and urologist to the South London Hospital for Women, of accumulating special experience of genito-urinary conditions peculiar to women, and has here placed the fruits of this experience at the disposal of the profession. The differences between the anatomy of the lower urinary tract in men and women render each liable to certain lesions which do not appear in the opposite sex, and it is with these that Miss Lewis deals rather than with diseases common to both. The section on the bladder is particularly helpful, since chronic cystitis is one of the commonest and most difficult conditions to combat amongst female maladies. We regret that she has not included in this chapter functional conditions, particularly functional frequency and enuresis. Another omission which we would like to see remedied in a future edition is nephroptosis, which is a condition found far more frequently in the female than in the male.

The work is well illustrated, the text clear, and the handling of the subject matter practical. This little book should certainly make and keep a place for itself in urological literature.

Principles of Preoperative and Postoperative Treatment

By REGINALD A. CUTTING, M.D., C.M., Assistant Professor of Surgery, Louisiana State University Medical Centre. New York: Paul B. Hoeber, Inc. p. 812. $10.

THIS book is both a work of reference upon recent advances in applied physiology and biochemistry, and a practical manual of pre- and post-operative treatment. Dr. Cutting possesses the qualifications essential to the writer of a good medical book: a wide and accurate knowledge of scientific literature, sound critical common sense, and a scholarly and lucid style. All recent investigations of real importance are discussed and explained in this volume, and in every case an attempt is made to assess the value of methods of treatment, while the author is careful to recommend no procedure which does not rest upon a sound basis, and which has not been adequately

absolute helplessness of the infant in developing the inborn tendency to overcome its "burning sense of inferiority." As growth and accomplishment reduce the gulf between the child and its surroundings, so do personal and egotistic interests tend to decrease; in this way some harmony between personal and social interests is made possible. He touched upon the factors which influence this development, and the rôle of the mother in promoting an atmosphere favourable to the production of courage and self-confidence.

The two words, courage and the community, he said, are characteristic of individual psychology. Courage is especially important, for without it true community feeling is not possible. As a viewpoint for distinguishing between different individuals, courage is better than intelligence, æsthetics, or morals. The intelligence of the courageous individual is quite different from that of the anxious or frightened person who tends to ask "What do people think of me?" "Do I like people?" and so on. This egotistic standpoint is especially apt to occur where an organ inferiority is present, or where the parents have misunderstood the child and have treated him wrongly. Both spoiling and snubbing foster excessive self-feeling. In the one case the children want what they feel to be their right, in the other they want what they have never had.

Dr. Seif indicated the ways in which confidence furthers a healthy relationship between the individual and the community, whereas a sense of deficiency is associated with the occurrence of neurotic, psychotic, or criminal tendencies. He regarded it as the aim of individual psychology to increase the courage and confidence of those with whom it deals, and so to create a more liveable world.

DISCUSSION

Dr. T. LAWSON said that Dr. Seif had spoken of the distance of the child from its environment and the duty of the parents to teach the child its social relationship, and asked whether the community feeling was latent or had to be taught.

Dr. F. G. CROOKSHANK spoke of the significance of the inferiority feeling upon which Dr. Seif had laid stress. He illustrated the interdependence of the individual and the community by an asylum story, in which the attendant, at the end of an observation which he had made as to the possible recovery of one of the patients, remarked "You may take it from me, Sir, a lunatic never has no friends."

Dr. O. H. WOODCOCK was interested in the way in which Dr. Seif had dealt with the rising generation, and with its need to learn to meet the world. He spoke of the value of the community feeling as taught by individual psychology, and suggested that the secret for the salvation of civilisation might be found here.

Dr. JAMES YOUNG agreed with the emphasis laid on the importance of the attitude of the individual to life. He observed that Dr. Seif had shown the philosophic or humane background of individual psychology.

Prof. LANGDON BROWN asked whether a neurotic could be a lady or a gentleman, since he was always trying to take more out of the common stock than he put in. He spoke of the responsibility of parenthood in giving some sense of security. The removal of the sense of insecurity found in so many patients was more important than growing cultures from their excretions.

Dr. SEIF, in reply, said that social feeling was inborn. In the course of his treatment the individual learnt to become what he really was, but had not had the chance to develop. The neurotic wished to give the appearance of coöperation. Sugar was more nourishing than saccharine, but the latter was many times sweeter. Individual psychology was one of the best foundations for a sound sociology. True love was associated with self-reliance and coöperation.

HUNTERIAN SOCIETY

ON Oct. 17th, at the first meeting of the session, Dr. NATHAN RAW delivered a presidential address entitled

Human and Bovine Tuberculosis

About 8 per cent. of samples of milk delivered into the large towns in England contained living tubercle bacilli, he said, while the deaths from tuberculosis in children up to 10 years of age were estimated at about 3000 per annum in Great Britain. This, however, did not represent the enormous amount of permanent crippling and deformity in those who had survived an attack. The eradication of tuberculosis from dairy cows was undoubtedly one of the most serious problems of the day, and the only real solution was to prevent the infection of calves. As early as 1906 Dr. Raw came to the conclusion that good results could not be obtained by the use of virulent cultures; accordingly, he secured pure cultures of the three strains of the tubercle bacilli and commenced the attempt to attenuate these by repeated sub-culture. Until the eighty-fourth generation of the culture no change in the virulence was noticeable. After that time, however, attenuation became marked, and the result of a long series of experiments had been the conclusion: (1) that it is possible to render the tubercle bacillus non-pathogenic; (2) that a vaccine prepared from this avirulent organism has enhanced immunising properties and can be used with perfect safety in large doses. The method adopted was the injection of cultures of human bacilli grown in the laboratory for 23 years, which were non-pathogenic and avirulent. So far, between 6000 and 7000 calves, chiefly of pedigree stock, had been immunised. The vaccine was injected when the calf was a week old, and again at the end of two weeks; and very satisfactory results had been obtained. He also used 23-year cultures in the treatment of human tuberculosis, again with very satisfactory results. They caused no reactions, no increase of pulse-rate, and no general disturbance.

Dr. Raw then discussed the question of mutation. Is it possible, he asked, that the bovine bacillus when introduced into the human body in children may lie dormant in the tissues for many years, and becoming adapted to its new environment, may assume the characteristics of a human bacillus, and thus set up human tuberculosis? It was certainly very difficult to explain why the bovine bacillus should almost invariably attack children, and why the human bacillus should so frequently attack the lungs between the ages of 18 and 25. These were questions of immense importance, and he put forward a few problems which awaited solution. Thus: (1) What is the life history of the T.B. before it enters living tissues? (2) Has it undergone a previous mutation? (3) Is infection of the lungs respiratory or alimentary? (4) Does direct respiratory infection from person to person occur? (5) Why do bovine infections in the human occur in childhood chiefly? (6) Why does

pulmonary tuberculosis (primary) occur in early adult life chiefly ? (7) Does the bovine bacillus from long residence in human tissues become transmuted into the human type, and so produce lung infection ? (8) Does a bovine infection of the human body produce immunity against the human bacillus and vice versa ? (9) Does a reinfection ever occur in the human ? (10) Can tubercle bacilli in human tissues be destroyed ? (11) Is the infection ever antenatal ? (12) Is there any hereditary predisposition to infection?

In conclusion, Dr. Raw strongly urged the appointment of a Government departmental commission to consider the best methods of dealing with and supplying milk to the public.

REVIEWS AND NOTICES OF BOOKS

Accidents, Neuroses, and Compensation

By JAMES H. HUDDLESON, Associate in Neurology, Columbia University. With a Foreword by J. RAMSEY HUNT, M.D., Sc.D. London: Baillière, Tindall and Cox. 1932. Pp. 256. 21*s*.

"ACETYLARSAN"

TRADE MARK

DIETHYLAMINE 3: ACETYLAMINO - 4 HYDROXYPHENYLARSINATE

"Acetylarsan" meets the need for an arsenical which is well tolerated and sufficiently potent in effect to permit its use by subcutaneous or intramuscular injection.

"Acetylarsan" is a pentavalent arsenical compound, supplied in the form of a clear colourless solution in sterilised ampoules, ready for injection.

"Acetylarsan" is indicated in all stages of syphilitic infection, being particularly useful for routine treatment in the primary and secondary stages, and for the visceral and nervous manifestations of late syphilis. Its rapid elimination and low toxicity allow frequent courses to be given.

MAY & BAKER LTD.
BATTERSEA LONDON, S.W.11

Telegrams: BISMUTH, LONDON. Telephone: BATTERSEA 1813 (6 lines) tested. In a few places he is content to place the evidence for and against some method before the reader, and to allow him to draw his own conclusions. The standard is good throughout and it is difficult to pick any part for special commendation; but the chapter upon blood transfusion may be mentioned as a practical treatise upon all aspects of the question, and that upon disturbances of acid-base equilibrium as a clear exposition of a subject that is apt to puzzle the reader whose laboratory days are far behind him. This book is a valuable addition to medical literature, and specially useful to the candidate for the Primary or Final Fellowship examinations. The print is excellent; the illustrations clear and well-chosen.

Electrotherapy and the Elements of Light Therapy

By RICHARD KOVÁCS, M.D., Clinical Professor and Director of Physical Therapy, Polyclinic Medical School and Hospital, New York. London: Henry Kimpton. 1932. Pp. 528. 30*s*.

THIS book will be read with interest by those who practise medical electrology and actinotherapy in this country. Doctors who wish only to learn the character and therapeutic properties of the different currents and rays for the purpose of prescribing treatment may find it too detailed, but specialists will appreciate an account of the experience and methods of American workers.

The introductory account of electrophysics is illustrated by helpful diagrams; Fig. 42, which shows the different electrical symbols, is especially instructive. The various currents, and the methods of utilising them, are well described. More space is devoted to the galvanic and faradic currents than in most American books on electrotherapy; on the other hand static electrical treatment, which is much more frequently administered in the United States than treatment by faradic and galvanic currents, receives relatively brief attention. The electrical reactions of muscle and nerves and the methods of testing them by the faradic and galvanic currents are fully discussed, and some notes are given of the uses of condensers for the same purpose. The determination of the chronaxie is briefly explained. Hydro-electrical baths do not receive much attention. The author points out the danger of supplying them with direct current from the main, and says that they must be insulated and that metal fittings and taps within reach of the patient should be avoided as much as possible. This is a scarcely adequate precaution. They should be absolutely out of reach. It is questionable, too, whether treatment by the galvanic current in a full-length bath has much therapeutic value; the quick sinusoidal current, on the other hand, in a full-length bath is really useful. A concise account of the uses respectively of infra-red, visible, and ultra-violet rays in treatment is supplied. The diseases which may advantageously be treated by electrical methods are considered in separate chapters under the headings of the different bodily systems. A chapter on electrotherapy in dermatology is contributed by Dr. J. J. Eller, and one on the treatment of diseases of the ear, nose, and throat by Dr. W. Morrison. A useful chapter on physical therapy in institutional practice concludes the book, which contains a glossary of electrical terms and a good index. Dr. Kovács insists on the importance of correct diagnosis and knowledge of pathology before physical treatment is given. Of diathermy he says that it "should not be used as a panacea for all sorts of undiagnosed painful conditions. A complete diagnosis, a definite conception of the underlying pathology to be influenced, and consideration of the individual equation in each patient are essential for its successful application." The book is well prepared, and the illustrations are clear and helpful.

A Descriptive Atlas of Radiographs

An Aid to Modern Clinical Methods. Second edition, revised and enlarged. By A. P. BERTWISTLE, M.B., Ch.B., F.R.C.S. Edin. London: Henry Kimpton. 1932. Pp. 552. With 767 illustrations. 42*s*.

THIS clear pictorial review of the scope of diagnostic radiology has now reached a second edition. The radiograms as before are well chosen and representative. Each is adequately described and most of them are accompanied by line drawing reductions as a guide to interpretation. Many are in silhouette, a technique that the author has devised for showing the fleshy outline; the print is blackened outside the margins of the flesh that, in the ordinary print, are either not seen or are only faintly visible. The scheme of the work is systematic, and the balance between the numbers of illustrations devoted to the various systems of the body in this edition seems to be well preserved. It is not clear why small sections should be labelled "nasal system" and "thyroid system." The illustrations are admirably reproduced.

La syringobulbie

By N. JONESCO-SISESTI. With a preface by Prof. GEORGES GUILLAIN. Paris: Masson et Cie. 1932. Pp. 391. Fr.70.

THIS monograph by Dr. Jonesco-Sisesti is based on the clinico-pathological study of a series of eleven cases personally observed. These cases in themselves represent a noteworthy contribution to the literature and are utilised for the study of several physiological problems connected with the functions of the medulla. Among the more interesting of the conclusions that emerge from this fine piece of work may be mentioned the occurrence of syringobulbia with sudden onset and the peculiar diagnostic difficulties such cases offer; and, in particular, the striking disproportion in some instances between the paucity of the symptoms and the severity of the bulbar lesions. To this point attention is also directed by Prof. Guillain in his foreword; he assures the reader that the researches of Dr. Jonesco-Sisesti prove that the medulla is by no means so "fragile" functionally as is commonly imagined, and that grave alterations of presumed "vital" sympathetic centres can coexist with maintenance of life. The volume also contains excerpts from a rich literature which with the personal cases serve as a basis for the discussion of various aspects of bulbar function and of special symptoms; among these are nystagmus, diplopia (it is curious to find authentic diplopia mentioned several times in connexion with bulbopontine lesions), ageusia, hiccup, the Argyll Robertson pupil. Pathologically, cavity formation, commonly latero-dorsal but sometimes mesial, is so constantly associated with glial proliferation as to make it impossible to separate rigidly syringobulbia from gliosis, gliomatosis, or glioma with cystic degeneration. No such complete review of syringobulbia and its particular features has hitherto been available.

THE LANCET

LONDON: SATURDAY, OCTOBER 22, 1932

THE POLICY OF SCHOOL-CLOSURE

THE recent disbanding of Stowe School "for safety's sake" on the appearance of two cases of poliomyelitis again forces us to question the wisdom of the policy of "school-closure" as a preventive measure. Most authorities believe that poliomyelitis is mainly spread by carriers, or unrecognised infections with the virus; also that carriers generally outnumber cases by more than a hundred to one. Children of pre-school age are more susceptible to, and suffer more severely from, infantile paralysis than do boys of public school age. On these grounds it seems scarcely fair to call the distribution of 500 potential carriers of the virus of poliomyelitis far and wide among the pre-school age-group a safety measure—at least for the community at large. Moreover, the closure of a school a fortnight after the appearance of the first case, as happened at Stowe, makes it as certain as we can be of anything in medicine, that many boys must have had time to become infected as virus carriers under the close living conditions of a school. It may be admitted that, for the inhabitants of a school itself, the risk of infection is diminished by school-closure. It can therefore be argued that since school authorities are in duty bound to do their best for the boys under their care, school-closure is their proper action when a serious disease appears among the individuals for whom they are immediately responsible. What happens to the other 40 million odd inhabitants of this island is not the business or responsibility of any school authority, but of the Ministry of Health. But one could imagine the outcry if, on the appearance of small-pox in an institution, the inhabitants were dispersed far and wide, without vaccination or quarantine of contacts. Yet in small-pox we can detect and trace all infected subjects, while in poliomyelitis only a small minority of those infected are discoverable, and what new chains of infection may be initiated by the distribution of unrecognised carriers from a single infected locality to many other districts, we have no means of guessing. In the case of diphtheria we do know that, when carriers from an infected institution have inadvertently been sent home, severe attacks of diphtheria have sometimes been reported among their young brothers or sisters.

The public health problem involved in school closure may be shortly stated thus. Will the number or severity of symptomatic poliomyelitis infections in the country as a whole be increased by distributing the virus carriers of a single infected institution all over the country, to homes where they are likely to meet specially susceptible subjects; or would keeping an infected sub-group isolated, under conditions which are known to favour the spread of the disease, in the end lead to a greater incidence of infantile paralysis in the community as a whole than would be caused by the dispersion of the infected sub-group? Unfortunately there is no certain answer to this question, but it would be more rational, from the little that is known, to confine an infection to one locality, than to risk spreading it to many. On the other hand, nowadays families of public-school boys are small, and perhaps most of Stowe's infected boys will return to homes in which there are no susceptible infants. Moreover, there is no doubt that those virus carriers who have young brothers or sisters are more likely to infect them as carriers than as cases of infantile paralysis.

With a little luck, therefore, it is quite likely that no cases of poliomyelitis may be traceable to the Stowe experiment. But we earnestly hope that Stowe, having made this experiment, will see it through—that the school authorities will try to get a census of the households to which their boys have returned, and a record of all febrile conditions likely to have been poliomyelitis that may possibly arise in these households during the next two or three months. Such data are sadly lacking, and it is only by immediately seizing such opportunities as the present one at Stowe that health authorities can obtain evidence which may enable them to say under what conditions, and for what infections, school-closure is of danger or benefit to the public's health.

◆

THE ÆTIOLOGY OF HODGKIN'S DISEASE

THE results of a concerted attack on an old and much-discussed problem—the ætiology of Hodgkin's disease—by a group of workers at St. Bartholomew's Hospital, are now available in a sumptuous volume just published under the title Rose Research on Lymphadenoma.[1] The inquiry was made possible by an endowment over a period of ten years, provided by Mrs. T. E. Rose in memory of a daughter who fell a victim to this disease. The endowment period came to an end in January, 1930, but fortunately since that date the investigation in its more purely experimental aspects has been continued by Dr. M. H. Gordon, working on behalf of the Medical Research Council. From 1920 to 1926, Dr. C. C. Twort, as the first Rose Research Fellow, carried out various investigations under the Fund which have been published elsewhere. In a brief summary of his work, which appeared in 1930,[2] Dr. Twort admitted that no new light on the ætiology of Hodgkin's disease had emerged, and that he had failed to confirm the observations of previous workers who had claimed to identify certain animal and vegetable parasites as causal agents. He did, however, draw attention to one observation he had made—viz., the occurrence of a local transitory

the dawn of history, and at the same time how hopelessly hampered it had been by the acceptation of theories that were natural, as they had their origin in physiological ignorance. But the classical teaching, coming down through Hippocrates and Galen, was never challenged, and that is an amazing fact, for the power of prestige has never been more forcibly illustrated. Much fine anatomical research and sound clinical observation was constantly forthcoming, but they never stimulated revolt from the accepted learning; all additions were fitted into fallacious premises, while theories degenerated into fancies as new discoveries required explanation on the old basis. This was the position of medical knowledge in which HARVEY found himself in the seventeenth century, heavily handicapped by ancient tradition, restricted by current knowledge, and unable, for lack of data, to explain the ultimate intention of the design which he revealed. "Nor," says the Orator, "could he complete his work, any more than any other explorer, for it was not a summary of existing knowledge from previous records, but an experimental stage in the development of a high argument." And that is why HARVEY's work always supplies a living text for comment and a living lesson for our instruction. His discovery was a step in an argument, which we to-day are following up. When the great discovery was made the mysteries of disease began to disappear at a geometrical rate of progression, and the story of progress is soundly grouped by Sir GEORGE NEWMAN under three headings: first, the recognition of a constant and stable internal environment for the regulation of health: secondly, the discovery of the cause and the methods of control in many infective diseases; and, thirdly, the establishment of the doctrines of immunity, with their promises of prevention, and their great performances. These are the steps which have been taken in the argument since HARVEY's day, grand steps, and each one opens up ways to further wisdom.

The second part of the Oration describes the intimate share which the Royal College of Physicians of London, HARVEY's college, has taken during the past 300 years in the promotion of preventive medicine. The public services enumerated as attributable to the College are of the first order. Before the General Medical Council took over the preparation of the British Pharmacopœia to do so was the responsibility of the College, laid upon them by their original constitution over a century before HARVEY's discovery. From 1518 to 1858 the official armamentarium of the physician was in the hands of the College. At the latter date the General Medical Council obtained the authorisation of a British pharmacopœia, but by that time the College had supervised the inventory of drugs and turned it from a medley of fanciful remedies, consonant with pre-HARVEY therapeutics, into a valuable compilation. More directly important to preventive medicine than the maintenance of a sound pharmacopœia is the orderly nomenclature of diseases as a necessary accompaniment of the registration of deaths. Here it deserved to be recorded that it was largely due to the public-spirited work of the Royal College of Physicians that the Registrar-General's reports have become the foundation of the best applications of preventive medicine. For other activities of the College having a close association with preventive medicine we refer readers to Sir GEORGE NEWMAN's words; they prove that "undoubtedly HARVEY's College has played a part in national therapeutics which illustrates signally the supreme value of his discovery."

◆

THE M.O.H. TELLS THE PUBLIC

EVERY medical officer of health reports year by year to the mayor, aldermen, and councillors of the city or borough, or to the chairman of the county council, by which he is appointed. His report covers a wide range of subjects, for he is the pooh-bah of public medicine, often being responsible, in addition to the general health services, for school medical inspection, maternity and child welfare, the control of tuberculosis and venereal diseases; moreover, he may be superintendent of the fever and maternity hospitals, chief administrative medical officer to the public assistance committee, and, it may be, borough meteorologist. Further, his report may include that of the public analyst and of the inspector of factories and workshops.

Nevertheless, it is not quite clear whether the report that he makes is accessible or not to the public. The Minister of Health certainly gives advice as to its form, but he has stated publicly that there are no regulations about publication, and he did not reply directly to an inquiry in Parliament[1] whether members of the public had a right to see it on demand. There have been cases, we are told, where the report of a medical officer of health to his sanitary committee has been held up at that stage and not allowed to go any further owing to its critical character. In some towns the practice prevails of sending a copy of the report to the public library, but this is apparently an act of grace on the part of the medical officer of health, whose attitude varies over the country probably as much as the size and format of his report—a want of symmetry which is the despair of the tidy librarian. One medical officer has recently stated that it is no business of the press to announce whether there are or are not cases of typhoid fever in his borough, somewhat to the surprise of the local journal. In Scotland they do these things rather differently, for ten years ago the Scottish Board of Health suggested[2] that arrangements should be made for judicious local distribution of reports as soon as they are available, and steps taken through the local press and otherwise to bring their contents effectively to the knowledge of the people "as a means of educating the citizens in the more important conditions of public health, of warning them against particular dangers, and inflammatory nodule after the subcutaneous inoculation in the guinea-pig of Hodgkin gland material. Control tissue of various kinds only rarely gave rise to such nodules. Attempts to reproduce this "inflammatory" reaction in passage experiment were unsuccessful.

---

[1] See THE LANCET, 1931, ii., 1385.

[2] Ibid., 1923, i., 47.

In 1928 a new plan of campaign was adopted. An executive committee consisting of Sir Thomas Horder, Prof. G. E. Gask, Prof. E. H. Kettle, and Dr. Gordon, was appointed to coöperate in the work and to supervise the various lines of investigation. They had the assistance of two Rose Research Fellows, Dr. Kenneth Stone and Dr. James Maxwell, and also of Dr. L. P. Garrod, Dr. E. R. Cullinan, and Dr. Beatrice D. Pullinger. It was early decided to prosecute inquiries along two main lines: (1) a search for organisms belonging to groups that might conceivably be associated with or responsible for lesions of granulomatous nature and which have in the past been suggested as possible ætiological agents in Hodgkin's disease; and (2) a search for a possible virus. The volume has now appeared which embodies the outcome of this joint investigation; it contains contributions by six workers (Horder, Gordon, Stone, Garrod, Cullinan, and Pullinger), and the major contribution, written by Dr. Gordon, is devoted to a detailed account of the investigations under these two headings. In spite of intensive and amply controlled research no evidence was found incriminating spirochætes, fungi, tubercle bacilli, or diphtheroids as primary and essential ætiological agents. The chief interest of the reader will be directed to some novel and unexpected observations of Dr. Gordon bearing on the virus theory of origin. He confirmed Dr. Twort's observation mentioned above, but was also unable to secure transmission in passage experiment. He then proceeded to investigate the effect of intracerebral inoculation of rabbits with Hodgkin gland macerates. For a few days after inoculation the rabbits would remain quiet. This latent period was followed by symptoms of incoördinate gait and paresis or paralysis of extremities. Death usually occurred at periods varying from a week or ten days to two months. Before intracerebral inoculation it was found advisable to macerate the gland material in the cold for a week or more, and with such technique it was possible to produce this "encephalitic" syndrome by inoculation of glands from five out of six recent cases of lymphadenoma and also of a dried gland removed from a fatal case two years previously. Gland material from a fairly extensive series of controls—carcinoma, sarcoma, leukæmia, tubercle, chronic adenitis, and so forth—failed entirely to produce this syndrome when inoculated by similar routes. Passage of the material through a Chamberland L2 filter did not yield a potent filtrate nor was it possible to produce a similar syndrome in normal rabbits by passage of brain material from rabbits which died. The "agent" responsible for the syndrome could withstand desiccation and was unaffected by 30 minutes' exposure to a temperature of 65° C. Curiously enough, the brains of animals which died showed no lesions of the infiltrative character that might be expected in a true encephalitis, and indeed, so far as we are informed in the present report, there were usually no obvious lesions of any kind present at autopsy. What the nature of the agent may be must, for the moment, remain obscure, but further developments will be awaited with interest. As lending some support to the view that Hodgkin's disease may ultimately be found to come within the virus category, attention is drawn to the recent important work in Sweden and Paris on lymphogranuloma inguinale which is now believed definitely to be a virus disease.

In the brief introductory contribution to the volume Sir Thomas Horder discusses the clinical concept of Hodgkin's disease, while Dr. Stone, Dr. Garrod, and Dr. Cullinan contribute useful information on the pathogenicity and serological classification of yeasts derived in the course of the inquiry from Hodgkin glands and other conditions. The volume closes with an important and profusely illustrated study by Dr. Pullinger of the histology and histogenesis of 39 cases of lymphadenoma. This paper demands most careful perusal and will be of interest not only to students of general pathology but to all histologists who may have in the course of their work to express opinions on glands removed for diagnostic purposes. Dr. Pullinger's conclusion is that lymphadenoma is neither a true malignant neoplasm nor a chronic inflammatory condition. She believes that it has most in common with the leukæmias since "like them it is essentially a progressive hyperplasia of one type of cell" (the reticulum cell).

◆

HARVEY AND HIS COLLEGE

In the Harveian Oration, delivered last Tuesday before the Royal College of Physicians of London by Sir George Newman, a fresh angle from which to view the patron saint of the College was discovered. This was something of an exploit seeing the number of consecutive years during which a pious estimate of Harvey's work and personality has been put on record in these discourses, which however have not followed any common pattern or had any stereotyped lay-out. On the contrary they form a most interesting corpus, and it is a tribute to the hero and his work that there should always be something fresh to say. Truly Harvey was one of those great men whose work fructifies in so many directions, fundamentally or in detail, that there is always some new tree—or may be forest, some new flower—or may be garden, owing its existence to the seed sown by him.

Sir George Newman sets out in convincing manner the derivation from Harvey's work of many of the preventive measures which are the feature of modern medicine. He divides his address into two parts, consecutive and interdependent, but distinctly two. In the first part he has reviewed, omitting the familiar biography, the position in which scientific medicine stood when Harvey made his discovery, and once again he shows how alive the science of medicine had been from and experience. One of the duties of the Morris Research Fellow will be to give advanced lectures upon the subjects in which he is specialising.

The work of the Institute has been broadened by the building of a new out-patient department and the addition of an electrotherapeutic department which will in the near future include facilities for deep X ray therapy. The radon supply depôt has not been quite working to capacity. The scientific problems connected with mass radiation by radium are now under examination by a special technical committee, and in the meantime the four-gramme bomb has been split into three one-gramme units allocated to the Cancer Hospital, the Middlesex Hospital, and University College Hospital, the remaining gramme being left by the King's Fund at the disposal of the Westminster Hospital. These units are being applied in a new apparatus, illustrated in the report, which can be brought to the bedside of a patient. Finally, the reports mention the receipt of the first consignments of summary cards, numbering about 1700, dealing with patients treated with national radium during the year 1930 when only about half the centres were yet in full working order.

TWO FORMS OF DIPHTHERIA BACILLUS

LAST year Anderson, Happold, McLeod, and Thomson,[1] working in Leeds, produced a paper describing two types of diphtheria bacillus, *B. diphtheriæ* "gravis" associated with severe and toxic cases, *B. diphtheriæ* "mitis" associated with milder cases of the disease. The two types were differentiated mainly by their growth characters on "tellurite chocolate agar" and by their power of fermenting certain polysaccharides, the gravis type being able to ferment starch and glycogen while the mitis type was without this power. The authors made it clear that in their opinion these observations justified a new classification of the diphtheria bacillus and might provide a solution of the much discussed problem of the alleged failure of antitoxin treatment in certain "malignant" outbreaks. It is obvious that the findings if substantiated are of great importance to clinician, bacteriologist, and serologist alike. Perhaps those most familiar with the bacteriology of diphtheria were most surprised at this claim of new discovery on such well-beaten ground. Other workers at once attempted to confirm the observation and at least three papers on the subject have already been published, the latest of which is to be found on p. 884 of this issue. The net conclusions of the three different sets of workers are in contradiction to those of Anderson and his colleagues. Menton,[2] Parish, Whately, and O'Brien,[3] and Wright and Rankin seem to agree that of the differential characters described by the Leeds workers only starch and glycogen fermentation could be relied on as sharp and objective. None of them could find any support for the view that the fermenting strains were any more clinically virulent than the non-fermentors. Parish, Whately, and O'Brien gave special attention to the serological aspects of the problem. They found that gravis and mitis forms were indistinguishable in animal virulence, and, as might have been expected, that animals immunised against the "Park-Williams" strain were completely protected against gravis strains. In therapeutic experiments on rabbits and guinea-pigs no difference could be recognised in the curative value of ordinary antitoxin for the two types. They also made the surprising observation that the gravis strains were consistently poorer producers of toxin in vitro than the mitis strains.

It is obvious from the work of Anderson and his colleagues that some virulent diphtheria bacilli ferment starch and glycogen while others do not; but so far, except in the Leeds observations, no connexion has been shown between this character and the clinical severity of the disease. A possible, though perhaps improbable, explanation of the Leeds findings is that a single "epidemic" strain of the bacillus with gravis properties was responsible for the bulk of the severe cases met with. Only a thorough study of the strains from the point of view of agglutination serology is likely to clear up this point, and it may be mentioned that special difficulties have been met with in the technique of agglutinating tests for the gravis strains, presumably owing to their tendency to form unstable suspensions. It would be premature to pass final judgment at the present moment on a question which, once raised, will have to be pursued to a final solution, but the claim of the Leeds workers to have established their main thesis can obviously not yet be allowed. The nature of "malignant" and "antitoxin-resisting" outbreaks of diphtheria still remains somewhat obscure, but there is little doubt that many if not all such outbreaks can be referred to late or inadequate antitoxin treatment rather than to any essential failure of ordinary antitoxin to act as a specific remedy.

THE HEALTH OF ALEXANDER THE GREAT

DR. Mario Bertolotti has written a book,[1] the latest contribution to the Biblioteca di Scienze Moderne, upon the physical disabilities of Alexander the Great, the wounds which he sustained and the diseases through which he passed, which will obtain interested attention from all students of medical history; when it is considered what the great conqueror suffered, as far as the records can be relied on, his exploits become even more wonderful than they appear in the usual chronicles. An accidental re-reading of Plutarch suggested to the author that a systematic research into the health of Alexander would shed new light on the problems of general history. While it must be left to professional historians to estimate how far this may have occurred, medical readers, who chance to know Italian, will be grateful for some capital reading. Dr. Bertolotti gives authorities for his facts, and has diligently studied the numerous references to Alexander made by a multitude of authors. While he draws his own deductions he makes no violent claims for their originality, and often points to other writers as having made similar reflections previously. The message of this useful historical note is that too little stress has been laid hitherto upon the health of the protagonists by those who reflect on and describe the events of history. Certainly the course of civilisation might have been altered radically in many instances if the physical make-up of the captains and kings had been different, and this should be considered in the estimates of what they did and for what their performances counted. Alexander the Great appears to have had some torticollis and facial asymmetry, despite his personal beauty. It seems that he fractured the base of his skull as a youth, had a penetrating wound of the thorax followed by an empyema, while his life was shortened by malaria. He came to the throne of Macedonia of securing that important coöperation and confidence between them and the health authorities and its staff which is essential to successful health administration." What is officially done in Scotland is no doubt the unofficial practice in many parts of England and Wales, where the reports are discussed at some detail by the local press. Probably every medical practitioner in the area gets a copy and public utility societies, interested in housing and the like, would no doubt be similarly obliged. The medical officer of health also has another way of reaching the local public through the circulation of *Better Health*, issued by the Society of M.O.H.'s, to which he is entitled to add pages of local interest.

[1] Alessandro Magno. By M. Bertolotti. Turin: Bocca Fratelli. Pp. 416. 56 lire.

Quite recently an interesting attempt is being made to popularise the public health services of local authorities by means of attractive little booklets issued by the council and written, or revised and approved, by the medical officer of health. Such booklets are already in circulation at Bath, Ealing, Ramsgate, and Torquay, and we understand that similar booklets are in preparation for Aberdeen, Belfast, Birkenhead, Kingston-on-Thames, and Wallasey. They are published for the public health department by Messrs. ED. J. BURROW and Co. (Cheltenham and London), to whom credit is due for their attractive form and get-up. Each report contains a directory of public health services in the area, a time-table of infant welfare centres, school medical department, tuberculosis and V.D. clinics, with useful addresses such as those of registrars of births and deaths, relieving officer, public vaccinators, and so on. Emphasis is laid in each on the fact that the public health department is open every day of the week and on Saturday morning to give advice on health matters, or to receive complaints of nuisances, and the statement occurs repeatedly that "no resident need live under insanitary conditions which can be remedied by law." There is also a recurring injunction to the public to raise the standard of care in the distribution of foodstuffs by patronising only those tradesmen who exercise care in handling them. No report emphasises perhaps as much as it might do the accessibility of the medical officer of health compared with that of other municipal officers; it is incomparably easier to get into the presence of the competent sanitary authority than it is of the borough engineer or town clerk. And this is as it should be, although at times it may lead to embarrassment of the health department.

ANNOTATIONS

ANOTHER YEAR OF RADIUM

WE learn from the reports published this week [1] that there is rather less national radium on loan than was expected when last year's allocation was made. This is due to the fact that certain centres, like the Mount Vernon Hospital and the Edinburgh Royal Infirmary, have not qualified for their full complement, although other centres, such as Sheffield and Manchester, have applied for additional loans. The amount of radium now on loan is as follows:—

	grammes.
National Radium Centres	14·655
Regional Radium Centres	0·768
Medical Research Council	1·000
National Physical Laboratory	0·186

the total being 16·609 g., a further 2·482 g. being allocated but not yet distributed. During the year £23,208 has been spent on the purchase of radium and containers, the total value of these now in the Trust's hands being estimated at £217,937. Responsibility for this, described as "the most costly substance known to man," rests heavily on the Commission, which has hitherto been able to obtain a specially low rate of premium owing to the faithful observation of very strict precautions. During the year however breaches of regulations at Liverpool, Edinburgh, and Glasgow have resulted in loss or damage to national radium which may lead to removal, at the discretion of the Commission, of any centre from the list of those privileged to enjoy such low rates. Unfortunately, owing to the rise in the market price of radium, the insured value and the amounts of premium have had to be raised by one-third. On the other hand, as there is now enough radium on loan to provide income to cover the Commission's overhead charges, it has been found practicable to reduce the rate of rental of radium from 2 to 1½ per cent.

The work of the Commission during the year has been concentrated on developing the national and regional centres. Five regional centres have been set up at Nottingham, Norwich, Southampton, Plymouth, and Stoke-on-Trent, to the last two of which a supply of radium has already been delivered. Nearly all the centres have accepted the three cardinal principles laid down by the Commission: (1) the appointment of a specially trained radium officer; (2) the proper coördination of ancillary services; and (3) the acceptance of patients for radium treatment from other hospitals in the area whether voluntary or rate-aided. The Commission reiterates that the principle of concentration implies no lack of sympathy with hospitals not selected as national centres; these it is hoped will coöperate in the task of advancing our knowledge of radium therapy by adopting the approved forms of clinical record and thus providing material for statistical purposes. The voluntary hospitals are pointedly reminded in the report that national radium is available to all patients for whom it is required, even if they are able to meet the full charges of the hospitals to which they are admitted; 80 per cent. however of radium beds must be reserved for the service of ordinary patients whether in the care of voluntary hospitals or of those administered by local authorities. The Commission deprecates any tendency to concentrate upon effecting cures in the more favourable cases to the detriment of a wider effort to relieve suffering in advanced cases which is an important function of radium therapy. The post-graduate centre formed by the liaison between the Mount Vernon Hospital and the Radium Institute has not developed in the expected way and is now regarded as more likely to become a rendezvous for the systematic study of the clinical side of radiotherapy. The appointment of radium officers to the national centres has lessened the need of special technical instruction for the staff of these centres, while many students are seeking clinical information

---

[1] Third Annual Reports of the National Radium Trust and Radium Commission, 1931–32. London: H.M. Stationery Office. Cmd. 4173. Pp. 43. 9d.

When the anæmia is due to accelerated destruction the mean cell volume tends to increase, since the reticulocytes are usually larger than normal. With decreased blood formation, though the findings are variable, the mean cell volume and hæmoglobin content are seldom greater than normal except in pernicious anæmia. Megalocytosis, he believes, is seldom seen except in the latter condition. Gordon Goodhart[2] has, however, recently published a series of megalocytic anæmias which do not appear to be of the typical pernicious type. The erythroblastic anæmia associated with steatorrhœa is also megalocytic, as determined by measurement of red cell diameter. Haden's observations further lead him to conclude that iron causes an increase in stroma as well as in hæmoglobin, since iron therapy in microcytic anæmia caused an increase in the volume of packed cells as well as of hæmoglobin. This is in accord with C. Price-Jones's[3] observations when determinations of red cell diameter as opposed to cell volume were made. He found that treatment with iron removed the microcytosis and reduced the variability. Further, by means of special staining, he demonstrated that the pale cells so characteristic of the condition were finally replaced by deeply stained cells presumably containing more hæmoglobin. Cell volume determinations alone fail to demonstrate any variation in the size or type of cell present in any sample giving only an average figure. Red cell diameter measurements enable an estimate of variability, both of size and cell character, to be made which are often of considerable importance. A combination of the two methods should therefore be employed whenever possible.

PREVENTIVE MEDICINE AND PUBLIC OPINION

At the Royal Institute of Public Health on Wednesday last Sir Ernest Graham-Little delivered an address with this title in which he laid about him manfully. The neglect of Sir Ronald Ross, the inconsistency of the Medical Research Council, the extravagance of subsidising researches along particular lines, the grave expenditure on public health services out of public funds, the lowness of the national physique, the wrongful treatment of our milk-supplies, and the unwarrantable expense of dealing with mental defectives—all alike formed allegations supporting the thesis that "there is a vast waste of money and of effort in our present measures to better the health of our people." That thesis cannot be taken as proved in the general way which Sir Ernest thinks—some of the expenditure, however great, and much of the effort do not constitute waste at all. In supporting his arguments, or rather his asseverations, by quotations from others, he does not seem to be aware that he might be asserting in accordance with his thesis answers to questions on which there is much room for differences of opinion; further, he said nothing of organised efforts which are meeting with success, or of resolutions already formed by competent experts to deal with many of the evils described. It is an excellent thing that a prominent public man should arouse the public conscience; the intention not to gloss over the many unhappy situations in which we live, with their obvious detriment to public health, is commendable; but whoever does these things ought to admit that his revelations are exposing ills which are well-known to many experienced workers, and should not forget to say that scientific and statistical investigation of varied sorts is inquiring into the soundness of diverse broad recommendations for reform. In the latter part of his address Sir Ernest, Member of Parliament for a university deeply interested in the medical profession, was on more certain ground, and in his advocacy of the institution of a pass qualification in medicine, given by the State, as a remedy for examinational procedures that do not serve the purposes of the general practitioner, he was following opinions that have often been expressed. He made no allusion, however, in his address to the grave objections to the institution of two orders in the profession, one of which is hall-marked as superior to the other; while the coincident training of undergraduate and graduate students at our medical schools has difficulties which he did not mention or does not appreciate. In his address to the Institute, we credit Sir Ernest with enthusiasm but not with judgment. He may have moved some hearers to a wish, not previously felt, that the sanitary world should be set aright, but he did not give them well-balanced information.

AIR EMBOLISM

It always seems astonishing that a bubble of air should be a cause of sudden death, and it was high time that this unsubstantial instrument of destruction took the fancy of a writer of detective stories. But now that the addicts have had plenty of time to enjoy Miss Dorothy Sayers's treatment of the subject it is perhaps justifiable to express doubt about the methods of the villain of the novel. Profiting by her training as a nurse in the Royal Free Hospital, this woman is in the habit of anæsthetising other characters, and injecting small quantities of air into their blood-vessels from a hypodermic syringe. The authorities, finding no evidence of a lethal agent, are helpless in face of a steadily rising death-rate, and even the medical reader may be annoyed to find himself no wiser. When the end comes, however, he may feel that fiction for once has proved itself a little stranger than truth; for it is hard to believe in the feasibility of induced air embolism as a practical method of murder.

There is no doubt, of course, that air injected into the circulation in quantities sufficient to replace a large mass of the blood in the heart chambers causes immediate failure of the circulation and instantaneous death. Some pathologists, indeed, adopt this as the most humane and least destructive method of killing their experimental animals. But in these cases the cause of death is clearly revealed by the presence of foamy blood in the heart. It is much less likely that a bubble of air small enough to escape detection could be relied upon to kill by entering the cerebral circulation and there setting up an air-lock in relation to some vital centre in the manner commonly implied by the term air embolism. This problem comes up periodically for debate, and it is at present being revived in relation to accidents in thoracic surgery. The condition described as pleural reflex, or "epilepsie ou eclampsie pleurale," consisting of sudden fatal syncope, convulsions, and hemiplegia, appearing in the course of induction of artificial pneumothorax and other thoracic operations, and hitherto considered to be something in the nature of reflex shock, is now suspected of being a manifestation of gas embolism in the brain. L. Croizier[1] has advocated this hypothesis in a lengthy discussion, wherein he also explains the mechanism by when he was 21, and died in his thirty-third year, having in 12 years established an empire over the world east of Greece, as far as it was known. The splendour of his conquests was dimmed by his outrageous passions, and it is the merit of this book to show how much his physical sufferings must have contributed to his moral defaults. His early death, following on his injuries and diseases, contributed to the collapse of his huge endeavours; if he had lived to hold the reins longer, a consolidated empire might have arisen in the early centres of civilisation, to the radical alteration of the world's history.

CARBOHYDRATE METABOLISM IN TOXIC GOITRE

It is generally accepted that glycosuria may occur in toxic goitre, but its incidence has been variously estimated at from 1 to over 90 per cent. The discrepancy may be found in the differing technique and care with which the sugar is sought. By examining separately all portions of urine passed over a period of one to two weeks, W. T. Anderson has demonstrated [1] glycosuria at some time in every one of 25 cases, all of which gave a diabetic type of curve with the glucose-tolerance test—that is to say, a curve higher and more protracted than in healthy controls. Using a less delicate technique, H. J. John has found [2] persistent hyperglycæmia in only 2 per cent. of toxic goitres, but this is still twice the incidence of diabetes in the general population. He points out, moreover, that no sugar-tolerance curve is specific in this condition, and that there is no strict relation between the severity of the thyroid disorder and the impairment of sugar tolerance. Among 9000 cases hyperglycæmia was present in 620; after thyroidectomy, and dietetic treatment with or without insulin, the sugar curve in the majority became normal in a few months, but in 200, or about 2 per cent. of the whole series, hyperglycæmia remained. In another series of cases he found that the reaction to ingested carbohydrate was of diabetic type in two-thirds, the renal threshold being low in the majority. John believes the disturbed carbohydrate metabolism in toxic goitre to be due not solely to the thyroid but to a predisposition to diabetes, or to a diminished reserve of the insulinogenic apparatus. The increase in the metabolic rate which accompanies the thyroid disorder puts an increased load on this apparatus, which becomes exhausted, diabetes resulting. In these cases glucose administration before and after operation, with or without insulin, is a logical procedure. Post-operative examinations will be necessary until there is satisfactory evidence that the carbohydrate metabolism has returned to normal. In most this will take place within a few months, but in others a mild dietary routine must be continued, with insulin in addition when indicated. The case described by Dr. A. W. Hendry in our present issue must be of rather exceptional nature. He describes a young woman with exophthalmic goitre accompanied by moderately severe diabetes, in whom treatment with insulin and diet over a period of six years resulted in a considerable gain in weight and disappearance of all signs of thyroid toxicity. Yet the diabetic state as judged by the blood-sugar level and the presence of ketosis was not improved in spite of increasing doses of insulin. After the administration, however, of a small daily dose of thyroid extract a striking change occurred—viz., frequent hypoglycæmic attacks, which necessitated a large reduction of the insulin dose. The diet was then increased, the urine remaining sugar- and acetone-free. Here, contrary to the usual experience, thyroid extract seems to have caused a sudden increase in sugar tolerance. Evidently there are interactions between the thyroid and the pancreas and their products which are still imperfectly understood.

THE CONGRESS ON RHEUMATISM

The third International Congress on Rheumatism was held in Paris at the end of last week and was largely attended, the representatives of foreign governments and rheumatism committees including Sir Humphry Rolleston and Sir William Willcox (Great Britain), Dr. A. M. McIntosh (Scottish Health Department), Dr. G. Kahlmeter (Sweden), Prof. B. Prusik (Czechoslovakia), Prof. S. Pisani (Italy), Prof. M. Kontchalowski (Russia), Dr. F. Kornmann (Switzerland), Dr. E. Freund (Austria), Dr. L. v. B. Pap (Hungary), Prof. I. Gunzburg (Belgium), and Dr. J. van Breemen (Holland). Prof. Fernand Bezançon, chairman of the French Committee on Rheumatism, presided, with Dr. Mathieu-Pierre Weil as secretary. The French Minister of Health opened the proceedings with a cordial speech and Sir Humphry Rolleston responded for foreign governments. Dr. Fortescue Fox, on behalf of the International League against Rheumatism, noted the progress of the movement in many countries since the first international committee was set up in Paris in April, 1925. He suggested that the subject was so vast that the League might well be content to confine itself for the present to the chronic rheumatisms of adult life, and spoke of the *terra incognita* of the abnormal reactions of rheumatic subjects to external impressions. At the ensuing sessions many reports were presented, on the initial symptoms of chronic rheumatism; on rheumatic diseases and tuberculosis, in which divergence of opinion was evident; and on rheumatic diseases and occupation. The last included interesting communications from Russia (Dr. Danischewski) and Sweden (Dr. Kahlmeter), while Dr. Vincent Coates (Bath) presented a statistical return of occupation in 18,000 cases at the three chief British spa hospitals. The President and Dr. Weil showed many cases illustrating the various forms of arthritis including some of nervous origin, and Dr. J. B. Mennell gave a practical demonstration of the diagnosis of abnormal conditions in the sacro-iliac joints and lumbar spine which was greatly appreciated.

It was decided to hold the next Congress on Rheumatism at Moscow in September, 1934.

THE SIZE OF THE RED CELLS

It is becoming clear that future workers, in discussing the significance of variations in the size of red cells, must consider not only the diameter of the red cell, but its volume and its hæmoglobin content. R. L. Haden [1] has lately made a valuable study of cell volume and hæmoglobin content in 444 normal and abnormal persons from which he concludes that in cases of sudden mechanical blood loss there is a change in the number of cells only, whereas with a chronic loss the cells become progressively smaller with a low hæmoglobin content.

---

[1] *Arch. Int. Med.*, 1932, xlix., 1029.

When the anæmia is due to accelerated destruction the mean cell volume tends to increase, since the reticulocytes are usually larger than normal. With decreased blood formation, though the findings are variable, the mean cell volume and hæmoglobin content are seldom greater than normal except in pernicious anæmia. Megalocytosis, he believes, is seldom seen except in the latter condition. Gordon Goodhart[2] has, however, recently published a series of megalocytic anæmias which do not appear to be of the typical pernicious type. The erythroblastic anæmia associated with steatorrhœa is also megalocytic, as determined by measurement of red cell diameter. Haden's observations further lead him to conclude that iron causes an increase in stroma as well as in hæmoglobin, since iron therapy in microcytic anæmia caused an increase in the volume of packed cells as well as of hæmoglobin. This is in accord with C. Price-Jones's[3] observations when determinations of red cell diameter as opposed to cell volume were made. He found that treatment with iron removed the microcytosis and reduced the variability. Further, by means of special staining, he demonstrated that the pale cells so characteristic of the condition were finally replaced by deeply stained cells presumably containing more hæmoglobin. Cell volume determinations alone fail to demonstrate any variation in the size or type of cell present in any sample giving only an average figure. Red cell diameter measurements enable an estimate of variability, both of size and cell character, to be made which are often of considerable importance. A combination of the two methods should therefore be employed whenever possible.

PREVENTIVE MEDICINE AND PUBLIC OPINION

At the Royal Institute of Public Health on Wednesday last Sir Ernest Graham-Little delivered an address with this title in which he laid about him manfully. The neglect of Sir Ronald Ross, the inconsistency of the Medical Research Council, the extravagance of subsidising researches along particular lines, the grave expenditure on public health services out of public funds, the lowness of the national physique, the wrongful treatment of our milk-supplies, and the unwarrantable expense of dealing with mental defectives—all alike formed allegations supporting the thesis that "there is a vast waste of money and of effort in our present measures to better the health of our people." That thesis cannot be taken as proved in the general way which Sir Ernest thinks—some of the expenditure, however great, and much of the effort do not constitute waste at all. In supporting his arguments, or rather his asseverations, by quotations from others, he does not seem to be aware that he might be asserting in accordance with his thesis answers to questions on which there is much room for differences of opinion; further, he said nothing of organised efforts which are meeting with success, or of resolutions already formed by competent experts to deal with many of the evils described. It is an excellent thing that a prominent public man should arouse the public conscience; the intention not to gloss over the many unhappy situations in which we live, with their obvious detriment to public health, is commendable; but whoever does these things ought to admit that his revelations are exposing ills which are well-known to many experienced workers, and should not forget to say that scientific and statistical investigation of varied sorts is inquiring into the soundness of diverse broad recommendations for reform. In the latter part of his address Sir Ernest, Member of Parliament for a university deeply interested in the medical profession, was on more certain ground, and in his advocacy of the institution of a pass qualification in medicine, given by the State, as a remedy for examinational procedures that do not serve the purposes of the general practitioner, he was following opinions that have often been expressed. He made no allusion, however, in his address to the grave objections to the institution of two orders in the profession, one of which is hall-marked as superior to the other; while the coincident training of undergraduate and graduate students at our medical schools has difficulties which he did not mention or does not appreciate. In his address to the Institute, we credit Sir Ernest with enthusiasm but not with judgment. He may have moved some hearers to a wish, not previously felt, that the sanitary world should be set aright, but he did not give them well-balanced information.

AIR EMBOLISM

It always seems astonishing that a bubble of air should be a cause of sudden death, and it was high time that this unsubstantial instrument of destruction took the fancy of a writer of detective stories. But now that the addicts have had plenty of time to enjoy Miss Dorothy Sayers's treatment of the subject it is perhaps justifiable to express doubt about the methods of the villain of the novel. Profiting by her training as a nurse in the Royal Free Hospital, this woman is in the habit of anæsthetising other characters, and injecting small quantities of air into their blood-vessels from a hypodermic syringe. The authorities, finding no evidence of a lethal agent, are helpless in face of a steadily rising death-rate, and even the medical reader may be annoyed to find himself no wiser. When the end comes, however, he may feel that fiction for once has proved itself a little stranger than truth; for it is hard to believe in the feasibility of induced air embolism as a practical method of murder.

There is no doubt, of course, that air injected into the circulation in quantities sufficient to replace a large mass of the blood in the heart chambers causes immediate failure of the circulation and instantaneous death. Some pathologists, indeed, adopt this as the most humane and least destructive method of killing their experimental animals. But in these cases the cause of death is clearly revealed by the presence of foamy blood in the heart. It is much less likely that a bubble of air small enough to escape detection could be relied upon to kill by entering the cerebral circulation and there setting up an air-lock in relation to some vital centre in the manner commonly implied by the term air embolism. This problem comes up periodically for debate, and it is at present being revived in relation to accidents in thoracic surgery. The condition described as pleural reflex, or "epilepsie ou eclampsie pleurale," consisting of sudden fatal syncope, convulsions, and hemiplegia, appearing in the course of induction of artificial pneumothorax and other thoracic operations, and hitherto considered to be something in the nature of reflex shock, is now suspected of being a manifestation of gas embolism in the brain. L. Croizier[1] has advocated this hypothesis in a lengthy discussion, wherein he also explains the mechanism by when he was 21, and died in his thirty-third year, having in 12 years established an empire over the world east of Greece, as far as it was known. The splendour of his conquests was dimmed by his outrageous passions, and it is the merit of this book to show how much his physical sufferings must have contributed to his moral defaults. His early death, following on his injuries and diseases, contributed to the collapse of his huge endeavours; if he had lived to hold the reins longer, a consolidated empire might have arisen in the early centres of civilisation, to the radical alteration of the world's history.

CARBOHYDRATE METABOLISM IN TOXIC GOITRE

It is generally accepted that glycosuria may occur in toxic goitre, but its incidence has been variously estimated at from 1 to over 90 per cent. The discrepancy may be found in the differing technique and care with which the sugar is sought. By examining separately all portions of urine passed over a period of one to two weeks, W. T. Anderson has demonstrated[1] glycosuria at some time in every one of 25 cases, all of which gave a diabetic type of curve with the glucose-tolerance test—that is to say, a curve higher and more protracted than in healthy controls. Using a less delicate technique, H. J. John has found[2] persistent hyperglycæmia in only 2 per cent. of toxic goitres, but this is still twice the incidence of diabetes in the general population. He points out, moreover, that no sugar-tolerance curve is specific in this condition, and that there is no strict relation between the severity of the thyroid disorder and the impairment of sugar tolerance. Among 9000 cases hyperglycæmia was present in 620; after thyroidectomy, and dietetic treatment with or without insulin, the sugar curve in the majority became normal in a few months, but in 200, or about 2 per cent. of the whole series, hyperglycæmia remained. In another series of cases he found that the reaction to ingested carbohydrate was of diabetic type in two-thirds, the renal threshold being low in the majority. John believes the disturbed carbohydrate metabolism in toxic goitre to be due not solely to the thyroid but to a predisposition to diabetes, or to a diminished reserve of the insulinogenic apparatus. The increase in the metabolic rate which accompanies the thyroid disorder puts an increased load on this apparatus, which becomes exhausted, diabetes resulting. In these cases glucose administration before and after operation, with or without insulin, is a logical procedure. Post-operative examinations will be necessary until there is satisfactory evidence that the carbohydrate metabolism has returned to normal. In most this will take place within a few months, but in others a mild dietary routine must be continued, with insulin in addition when indicated. The case described by Dr. A. W. Hendry in our present issue must be of rather exceptional nature. He describes a young woman with exophthalmic goitre accompanied by moderately severe diabetes, in whom treatment with insulin and diet over a period of six years resulted in a considerable gain in weight and disappearance of all signs of thyroid toxicity. Yet the diabetic state as judged by the blood-sugar level and the presence of ketosis was not improved in spite of increasing doses of insulin. After the administration, however, of a small daily dose of thyroid extract a striking change occurred—viz., frequent hypoglycæmic attacks, which necessitated a large reduction of the insulin dose. The diet was then increased, the urine remaining sugar- and acetone-free. Here, contrary to the usual experience, thyroid extract seems to have caused a sudden increase in sugar tolerance. Evidently there are interactions between the thyroid and the pancreas and their products which are still imperfectly understood.

POST-GRADUATE LECTURES

WE continue this week the publication of summaries of lectures lately given to post-graduates at teaching hospitals. Prof. de Wesselow spoke at St. Thomas's, Mr. Banister at Charing Cross, and Dr. Hutchison and Mr. Milne at the London Hospital.

DIABETIC COMA

(PROF. O. L. V. DE WESSELOW)

IN the first place, what does coma in the diabetic imply? I think we should agree in attributing it to a lack of active insulin in the patient. In the absence of adequate insulin an inadequate amount of carbohydrate is oxidised, and with this failure to oxidise carbohydrate excessive amounts of the so-called ketone bodies are formed.

Further, in most cases it would seem that this failure of insulin-production is a temporary aggravation of an existing defect in the islands of Langerhans, rather than the last stage of a slow but steady decline in the function of these structures. We are dealing with a temporary crisis of a highly dangerous nature, but if once we can tide the patient over this phase we shall usually find that, as far as his carbohydrate tolerance is concerned, he is in much the same condition as he was before coma supervened; the ultimate outlook is relatively favourable.

What then precipitates this temporary failure in insular function? Undoubtedly in the great majority of cases the factor is infection. Anyone who is accustomed to the care of diabetics realises the disastrous effect of infection of any kind on their carbohydrate tolerance—that is, on their insulin-production. The diabetic clinic in summer is relatively uninteresting; during the winter months, with the onset of respiratory infections, a constant readjustment of insulin dosage become necessary. It is surprising how a scarcely noticed cold will lead to the reappearance of sugar in the urine.

We must aim then at shielding the diabetic from infection. Further, if the diabetic contracts an infection there must be no hesitation in increasing his insulin dosage if sugar and ketone bodies appear in the urine. In the past the risk of coma in the infected diabetic has been enormously increased by a wholly unwarranted fear of hypoglycæmic reactions. The febrile patient was unable to take his ordinary diet. Insulin was withheld for fear of reactions and coma ensued. Actually, the febrile diabetic needs more, not less, insulin; his hyperglycæmia is usually difficult to control, and, however poor his appetite, the dose of insulin can always be covered by adequate carbohydrate in the shape of glucose lemonade or bread and milk.

Now let us turn to the patient in whom coma has developed. The first point that will strike you is the hyperpnœa. This hyperpnœa which, as you know, is the result of stimulation of the respiratory centre by the altered reaction of the blood, is useful, and even essential, in that by removing excessive amounts of carbonic acid from the blood it tends to maintain the reaction of that fluid at something near its usual figure. Without hyperpnœa a change in the reaction of the blood to a level incompatible with life would soon ensue. Hyperpnœa however, when maintained over long periods, is not free from dangerous consequences. In the first place, the heat-loss in the expired air is considerable—hence the low temperature of the comatose patient. Secondly, and more important, enormous quantities of water pass off from the lungs. It is calculated that 5000 c.cm. of water per diem may be lost in this way by the comatose patient against the normal quantity of 500–1000 c.cm. The result of this loss is extreme desiccation. Even though the blood is the last tissue in the body to be affected by desiccation, the blood volume in coma may be reduced by as much as 30 per cent., while the leucocytes, red blood-cells, and proteins of the plasma show a corresponding rise. Desiccation then is one of the most important problems in the treatment of coma.

A second feature of coma is cardiac failure—a progressive increase in pulse-rate and a steady fall in the strength of the heart beat. This is understandable when we consider the strain thrown on the heart by the hyperpnœa, the increased viscosity of the blood, and the possible toxic effect of the ketone bodies. When we add to this the fact that the cardiac muscle is often damaged by a coexisting infection, and that in some diabetics coronary arteriosclerosis is present, cardiac failure is to be expected.

Lastly, it is not always realised that severe renal damage is a concomitant of diabetic coma. This fact, which was well recognised in the last century, has only again come into prominence as an explanation of some cases of failure of insulin therapy. Occasionally a patient recovers from diabetic coma only to die from uræmia. An examination of the urine in coma will usually show the presence of albumin and casts.

The main outlines of treatment are obvious. In the first place, we must inhibit further production of the ketone bodies. This we accomplish by providing enough insulin to allow adequate carbohydrate oxidation to be resumed. Secondly, the existing concentration of the ketone bodies in the tissue fluid must be reduced, and this can only be effected by the kidneys. For the kidneys to do their work ample water must be available, and the renal circulation must be intact. We have therefore to introduce fluid into the desiccated body and as far as we can to support the heart. Lastly, time is of the first importance. In view of possible cardiac and renal failure we cannot afford to temporise.

My own view is that these cases are best cared for in an institution, provided that their removal does not entail a delay of more than an hour or two in commencing intensive treatment. Before transport an injection of insulin should of course be given. Many cases, however, must of necessity be treated in their own homes, where blood-sugar estimations will not be possible. Your difficulty here will be to avoid hypoglycæmic coma while at the same time giving an adequate insulin dosage. This can be effected easily enough by keeping the blood-sugar high throughout the treatment. A high blood-sugar is harmless. It is the excess of ketone bodies in the blood which constitutes the danger. For treatment you will need insulin, glucose, an infusion set, some Fehling's solution, and a 10 per cent. solution of ferric chloride. A nurse is essential for the general care of the patient, to force fluids as soon as swallowing becomes possible, and for the collection and labelling of all specimens of urine passed. As long as glycosuria is present the patient is not hypoglycæmic. The urine will therefore give you warning of the possible presence of hypoglycæmia, and by testing with ferric chloride you can follow the reduction of the ketonæmia. In a deeply comatose patient it is advisable to start which air may enter the circulation at the site of minute wounds of the lung, impelled by the negative pressure existing in the pulmonary veins during inspiration. Sergent, Baumgartner, and Kourilsky[2] have described a case in which, during an operation on the lungs, the hemiplegia and other signs were so clearly indicative of a localised cerebral lesion as to convince them that air embolism was the cause. They cite a number of authors who have had like experiences, and they mention two cases in which observers claim to have detected the site of embolism marked by foci of softening in the brain. Absolute proof that air embolism is the cause of these accidents is, of course, difficult to furnish, chiefly because the presence of gas in blood-vessels post mortem is a not uncommon result of bacterial growth in the cadaver, and therefore no criterion of the state of affairs during life. But Croizier has shown experimentally that small amounts of air injected directly into the carotids of animals can produce manifestations corresponding to those observed in the cases mentioned, and there is little reason to doubt that such accidents as air embolism can occur in man. That they must be rare was shown by M. Joannides and G. D. Tsoulos,[3] who demonstrated that dogs were able to withstand as much as 300 c.cm. of air injected into their femoral veins provided the injection was given slowly (over a period of 30–40 minutes). Probably, therefore, the number of fatal accidents of this kind is exceedingly small in comparison with the number of cases in which air finds its way into the circulation.

BIRTH CONTROL AND EXTRA-UTERINE GESTATION

An attempt to correlate the increased incidence of extra-uterine gestation in Switzerland with the extension of the practice of conception control and criminal abortion has recently been made by Hans Guggisberg.[4] Attempts to prevent conception by the introduction of intra-uterine stems or silver rings, such as that of Gräfenberg, are by no means always successful. He quotes H. Gummert's report[5] of 92 cases in which pregnancy occurred after use of one or other of these methods, 78 of these pregnancies ending in abortion, usually septic. Guggisberg holds that tubes or rings often give rise ultimately to tubal pregnancy, because of the permanent changes set up in the tube following inflammatory complications. He deprecates also contraceptive methods involving the use of vaginal occlusive pessaries, which in his experience may lead to sepsis by causing retention of secretions. Attempts at criminal abortion are not infrequently made in patients who have tubal pregnancy with disastrous results, such as tubal rupture complicated by sepsis. Not only is the diagnosis in such cases extremely difficult, but the dangers of laparotomy are much increased. Two such cases are here related, both of which recovered after laparotomy. Guggisberg holds that the control of family regulation should be undertaken by the State, though he makes no suggestion as to the methods of regulation that the State should adopt. Kurt Kaiser,[6] writing from Silesia, is also of opinion that the increase of criminal abortion has led to a greater incidence of ectopic gestation, but much more evidence will have to be adduced before this can be accepted.

The possibility of injury being caused through the damming back of cervical secretions has been frequently discussed. This possibility especially arises in connexion with close fitting cervical caps made of metal which, in certain continental countries, are placed in position at the end of a menstrual period and left in situ until dislodged by the menstrual flow occurring at the next period. Retention of secretion is unlikely to occur when a rubber cervical cap is employed which is placed in position for short periods of not more than ten hours. It is especially improbable if the rubber cap has a high rubber dome. With this and with the so-called Dutch pessary, which roofs over the vaginal vault, fitting anteriorly above the symphysis pubis and behind in the posterior fornix, the danger is negligible, and it clearly does not arise at all when a sheath is used. The criticism adduced by Guggisberg of the use of contraceptives therefore only applies to certain types of these. In this country the Gräfenberg ring method is now generally regarded as unreliable and potentially harmful.

HUMAN AND BOVINE TUBERCULOSIS

The presidential address delivered before the Hunterian Society on Monday last by Dr. Nathan Raw, was based on his personal experience in hospital and laboratory during the last 40 years, most of the observations being made during his superintendency of the Mill Road Infirmary, Liverpool. In 1901 Koch stated, at an international conference in this country, that bovine tuberculosis could not be conveyed to man, and seven years later he repeated the statement at an international conference at Washington. Dr. Raw told how, in secret session, a group of experts—he and Sims Woodhead representing Great Britain—met Koch and persuaded him to modify his views, and the universal medical view to-day is that bovine bacillus conveyed to the human subject causes a large amount of tuberculosis. The conveyance of bovine bacilli, especially to the young by milk, formed the substance of his address; this concluded with a number of questions awaiting solution, which are enumerated in the summary of the proceedings at the meeting of the society (see p. 900).

The Bradshaw lecture of the Royal College of Physicians of London will be given on Nov. 1st by Dr. Dugald Baird, whose subject will be the Upper Urinary Tract in Pregnancy. On Nov. 8th and 10th Dr. James Collier is to deliver the FitzPatrick lectures on the Development of Neurology from the commencement of the Nineteenth Century to the Present Time; and on the 22nd Prof. L. P. Jacks the Lloyd Roberts lecture, on the Liberal Education of the Body. All these lectures will be given at 5 P.M. in the College, Pall Mall East, and will be open to members of the medical profession on presentation of their cards.

The study of the relationship between oxygenation of the tissues and the maintenance of good cardiovascular function during spinal anæsthesia, annotated in this column last week (p. 852), was made by Dr. M. H. Seevers and Dr. R. M. Waters, of Madison, Wisconsin. We regret the inadvertent omission of the names of the authors.

type rest is the only treatment which is of value, and any attempt to make the uterus empty itself is dangerous.

Many factors may be involved in the production of disorderly action of the uterus, as found in the first type. It may result from some mechanical abnormality of the baby; in cases of occipito-posterior presentation, for example, the uterus seldom acts quite as it should. The contractions are short and painful during the first stage and are felt in front instead of at the back as a rule. Early rupture of the membranes and breech presentations may also produce irregular uterine action. The attendant should concentrate on treating the abnormality, not the uterus.

A second cause of disorderly action is muscular inefficiency of the uterus. This may be called true uterine inertia. There are poor, short, not very uncomfortable contractions, and labour may go on as long as 36 hours without the patient being at all exhausted or troubled. This type of case is usually overtreated; it is better to leave the sluggish uterus alone. Incoördinate action of the uterine muscle is a third cause. Nowadays it is unfashionable to talk of uterine polarity, and many obstetricians refuse to accept the idea of a preliminary relaxation of the cervical muscle. Nevertheless, there are some cases in which this relaxation fails to occur, and in which the upper part of the uterus is doing its best while the lower part resists. Rigidity of the cervix is not a good name for this condition, which is really incoördinate action of the uterine muscle. A fourth cause of irregular action takes origin from the higher centres and arises as a result of fear. The action of adrenaline upon excised uterine muscle is to stop or diminish contractions, and the same effect is obtained if adrenaline is injected during labour. When the patient is frightened large quantities of adrenaline are thrown into the circulation.

In a fifth and final type, uterine inefficiency depends not so much on poor uterine action as on a defensive contraction of the voluntary muscles with each pain. This also occurs in frightened patients. Labour usually progresses normally until the pains begin to get stronger, and then progress is retarded. The patient contracts all the muscles of her body with each pain, as though trying to put off the moment of delivery. In these patients miraculous results follow the use of some form of anæsthesia.

In one case of the kind the patient had had one previous child by breech presentation. During her second labour, her husband was continually popping in and out of the room and remarking: "I hope to God it's going to be a boy." He asked his wife repeatedly and minutely how she felt. The nurse, on the other hand, kept saying: "I do hope your baby's all right." When the membranes ruptured the fluid was brownish, and the nurse exclaimed: "There now, look at that! I must ring up the doctor at once." By this time the patient was in terror lest she was going to have a dead baby, and subconsciously she was doing all she could to postpone delivery by contracting up her muscles. At the end of three hours she was extremely tired, and chloroform was started, being given in small doses. Within 20 minutes—as soon, in fact, as the voluntary muscles were relaxed—the living child was born.

The recognition of the various types of uterine inertia begins with antenatal care. Not only the mechanical conditions present but the patient's general health must be considered. It is worth while trying to find out what the patient is feeling about her confinement, but she is often reserved and at first sight she does not appear to be worried. Complete vaginal examination should be delayed until the last fortnight of pregnancy; a vaginal examination is no part of antenatal care during the first half of pregnancy, and those who make one should have a definite reason. At an examination made during the last week or two of pregnancy it is possible to recognise those cases which are going to have disorderly action owing to resistance of the lower part of the uterus. If the vagina is not well lubricated, if the vaginal walls do not readily admit the examining finger and the patient experiences discomfort, there is likely to be difficulty in labour, more especially if the cervix feels as though it has a core of solid rubber.

During labour itself the attendant should be able to distinguish between delay due to muscular incoördination and delay due to nervous inhibition of pains. The patient in whom the musculature is not equal to its job may be in labour for a long time without suffering much. She is able to potter about the room, and is untroubled about herself; if she is given a hot bath and an enema the uterus is often stimulated into action, and she does well. The patient of the second type has short, sharp, irregular pains without much progress being made. She wants to go to bed. If this type of patient is given enemas and baths her fear will be stimulated and no good will be done. When the patient is obsessed with fear, and is showing a defensive contraction of all her muscles at every pain, some method akin to twilight sleep gives excellent results. But the action of the drug used must be supported by a tranquil environment—by pulling down the blinds and by keeping people out of the room. In the late stage of labour, chloroform anæsthesia combined with an injection of pituitrin can be given, but must be used carefully. Chloral, given earlier, is likely to have one of two types of action. After a dose of grs. 30, one patient will go to sleep for some hours and then wake and do well; another will suddenly deliver herself in about 20 minutes, the reason being, of course, that the first woman is of the flaccid type who needs rest, while the second has spasm of some part of the uterine muscle which is relaxed by the drug. The uterus is at last able to do its best, and out comes the baby. Our attitude to our patients should reflect that of King Henry towards his soldiers before the battle, and, slightly modified, the lines might run:

> "O God of battles! Steel my *patients'* hearts;
> Possess them not with fear; take from them now
> The sense of reckoning, if the opposed *hours*
> Pluck their hearts from them."

THE UNDEPENDABLE KNEE

(MR. ROBERT MILNE)

FOR the patient, a knee has not recovered from an injury until he feels he can depend upon it. The knee should be capable of extending until the leg is straight and bending until the calf touches the hamstrings. There should be no lateral movement when the knee is straight, but when the knee is bent it should be possible to rotate the tibia slightly on the femur. When the legs are straight, moreover, there should be no difference between the quadriceps muscles on the two sides. The quadriceps is the most important factor in making a knee stable.

Since the advent of the camera and the cinematograph it has become possible to analyse the mechanism of walking. When the right foot is on the ground and the left foot in the act of passing it, the right knee is seen to be, not straight, but slightly bent. It only straightens when the left foot reaches the ground and it becomes necessary to push off with the right foot to give the body its forward impetus. The angle which the foremost knee makes in walking is about 165°; if there was no muscular action to maintain this angle the knee would collapse. Text-books of anatomy state that the purpose of the quadriceps is to straighten the knee, and though it is true that it treatment with 1 to 1½ pints of normal saline containing 5 per cent. glucose given intravenously. To this 100 units of insulin should be added. The infusion should be given slowly, at least 30 minutes being taken over the process. Thereafter I should advise you to see the patient at least every three hours until you are satisfied that recovery is well started. The indications of improvement which you should look for are diminution in the hyperpnœa, strengthening and slowing of the pulse, recovery of consciousness, and diminution of the ferric chloride reaction in the urine. The further course of treatment must depend on your findings. If improved, another 20 units of insulin covered by 50 g. of glucose every three hours for the next 12 hours will probably suffice to carry the patient on. In severe cases larger doses of insulin, given intravenously, if there are indications of failing circulation, are needed. As long as you cover your insulin by glucose, introduced orally, subcutaneously, or intravenously, and take the precaution of satisfying yourself that glycosuria is present, the risk of hypoglycæmia need not worry you. Adequate insulin and adequate fluid are the two great essentials of treatment.

CHRONIC DIARRHŒA

(DR. ROBERT HUTCHISON)

CHRONIC diarrhœa is a symptom and not a disease, and diagnosis has usually to be made by exclusion. Some form of classification is therefore necessary, and the following is suggested :—

1. *Gastrogenous*, due to achlorhydria or to achylia. Why these sometimes lead to diarrhœa is not understood; it is apparently not a question of "gastric hurry" nor of the absence of the antiseptic action of normal gastric juice. The stools are loose, and may occur either after meals or between them; they contain undigested connective tissue.

2. *Fatty*, where the stools contain undigested fat. This variety includes the rare condition *congenital steatorrhœa*, in which liquid fat is present; *pancreatic diarrhœa*, due to failure of pancreatic secretion to enter the bowel and in which split fat is present in excess, as well as undigested muscle-fibres; *cœliac disease*, met with in children and occasionally in adults, and due apparently to a failure of absorption of fats; and, lastly, rare cases in which *blocking of lacteals*—e.g., in tabes mesenterica—also interferes with fat absorption.

3. *Enteritis*, a catarrh of the small intestine which may arise from various causes—e.g., alcoholism, tuberculosis, and uræmia (eliminative diarrhœa)—but sometimes from unknown causes. The stools are fluid, and contain bile-stained mucus on microscopical examination. They may be offensive from decomposition of proteins (putrefactive diarrhœa), or sour and bubbling from fermentation of carbohydrates (fermentative diarrhœa).

4. *Colonic.*—In this large group the seat of the trouble is in the colon. One may distinguish the following varieties: (*a*) *catarrhal*—a simple catarrh of the bowel—in which the motions tend to occur in the early part of the day (morning diarrhœa); (*b*) *ulcerative*, due to ulcers in the colon. These may be either dysenteric or non-dysenteric (ulcerative colitis); (*c*) *obstructive*, where the diarrhœa occurs as an "overflow." The obstruction may be due simply to an accumulation of scybala (spurious diarrhœa) or to non-malignant—e.g., tuberculous—or, far more commonly, malignant tumours.

In all cases of chronic diarrhœa the stools are apt to contain visible mucus, and, if ulceration is present, blood. Tenesmus is also frequent. The general nutrition, however, suffers less than in cases of enteritis.

5. *Neurogenic*, where the nerve mechanism is alone at fault. One may distinguish as varieties: (*a*) *reflex*, an exaggerated reflex excitability of the bowel. If the motions occur immediately on the taking of food the diarrhœa is spoken of as *lienteric*; (*b*) *emotional* or *psychogenic*, where fear, anxiety, and other emotional states "fire off" the bowel.

DIAGNOSIS AND TREATMENT

The differential *diagnosis* of these varieties involves the taking of a careful history; thorough physical examination, both abdominal and general; an inspection of the stools, both by the naked eye and the microscope; and a digital exploration of the rectum. In some cases it may also be necessary to use the sigmoidoscope; to give a test-meal, and to have a chemical analysis of the motions for fat, &c. An X ray examination after a barium enema is often helpful. In spite, however, of the most careful investigation the cause of the diarrhœa frequently remains unexplained.

Treatment depends upon the cause, and the routine use of astringents is to be avoided. *Diet* is of the first importance, but over-strict dieting is harmful. As a general rule, a low-residue diet is to be chosen, but it must be modified in special cases. Thus, in gastrogenic and in putrefactive diarrhœa meat must be restricted; and in the fatty group, fats; in the fermentative, carbohydrates. *Drugs* are of limited value, but hydrochloric acid is a specific in the gastrogenous group, moderate doses usually sufficing. Calcium carbonate and phosphate are of use in enteritis, especially in the fermentative form, whilst bromides often control neurogenic diarrhœa. Opium should be used sparingly, and chiefly for pain and tenesmus. As a means of "locking up" the bowel in the psychogenic cases it is liable to abuse, but is of great help in small doses before meals in the lienteric type. Emetine should be given in the dysenteric group of amœbic origin, and castor oil in "spurious" diarrhœa. Pancreatic preparations are indicated when unsplit fat is present in the motions in excess. *Lavage* of the bowel can easily be overdone, but is helpful to a limited extent in simple ulcerative colitis, normal saline being probably as useful as astringents. *Vaccines* are generally useless. *Surgical* intervention is the only treatment in malignant and tuberculous obstructive diarrhœa. It is also called for in some cases of ulcerative colitis, ileostomy or cæcostomy being the operations of choice.

UTERINE INERTIA

(MR. BRIGHT BANISTER)

THE subject of uterine inertia is not presented to students in a satisfactory way. Inertia is the property of matter whereby it retains its state of rest or movement in a linear direction unless some outside cause appears to alter it, but the term is commonly used to describe a motionless body. The classical derivation, however, means "without skill," and in considering uterine inertia we are considering why the uterus is acting without skill, not why it is failing to act at all.

It is misleading to talk of primary and secondary uterine inertia, for the two types are diametrically opposed, and are not two phases of the same condition. In the so-called primary type uterine action is sluggish and irregular from the outset of labour, while in the secondary type the uterus is exhausted after having done its best. Treatment in the first type aims at improving the action of the uterus; in the second

SPECIAL ARTICLES

MEDICINE AND THE LAW

Professional Secrecy

SOME account was given in THE LANCET last week of the extent to which the law appears to expect a medical practitioner to disclose information which immemorial professional tradition regards as confidential inasmuch as the knowledge has been revealed by a patient in the course of medical treatment. Mention was made of the carefully framed resolutions of the Royal College of Physicians of London concerning the duties of medical practitioners in relation to cases of criminal abortion, published in 1916, which ran thus :—

> The College is of opinion—
>
> 1. That a moral obligation rests upon every medical practitioner to respect the confidence of his patient ; and that without her consent he is not justified in disclosing information obtained in the course of his professional attendance on her.
>
> 2. That every medical practitioner who is convinced that criminal abortion has been practised on his patient, should urge her, especially when she is likely to die, to make a statement which may be taken as evidence against the person who has performed the operation, provided always that her chances of recovery are not thereby prejudiced.
>
> 3. That in the event of her refusal to make such a statement, he is under no legal obligation (so the College is advised) to take further action, but he should continue to attend the patient to the best of his ability.
>
> 4. That before taking any action which may lead to legal proceedings a medical practitioner will be wise to obtain the best medical and legal advice available, both to ensure that the patient's statement may have value as legal evidence and to safeguard his own interests, since in the present state of the law there is no certainty that he will be protected against subsequent litigation.
>
> 5. That if the patient should die he should refuse to give a certificate of the cause of death and should communicate with the coroner.
>
> The College has been advised :—
>
> 1. That the medical practitioner is under no legal obligation either to urge the patient to make a statement, or, if she refuses to do so, to take any further action.
>
> 2. That when a patient who is dangerously ill consents to give evidence her statement may be taken in one of the following ways :—
>
> (a) A magistrate may visit her to receive her deposition on oath or affirmation. Even if criminal proceedings have not already been instituted, her deposition will be admissible in evidence in the event of her death provided that reasonable written notice of the intention to take her statement was served on the accused person and he or his legal adviser had full opportunity of cross-examining.
>
> (b) If the patient has an unqualified belief that she will shortly die, and only in these circumstances, her dying declaration will be admissible. Such a declaration may be made to the medical practitioner, or to any other person. It need not be in writing, and if reduced into writing it need not be signed by the patient nor witnessed by any other person, though it is desirable that both should be done, or that, if the patient is unable to sign, she should make her mark. If possible, the declaration should be in the actual words of the patient, and if questions are put, the questions and answers should both be given, but this is not essential. If the declaration cannot there and then be reduced into writing, it is desirable that the person to whom it is made should make a complete note of it as soon as possible.

It will be noted that in particular cases of doubt and difficulty the doctor is recommended to consult solicitors ; those best qualified to give guidance are the legal advisers whose work specially familiarises them with problems arising in the course of medical practice and in the defence of medical practitioners.

THE QUESTION OF PRIVILEGE

The resolutions of the Royal College were evoked by a question of disclosure in criminal matters. The lay public, it seems, needs occasionally to be reminded that the principle of professional secrecy has the widest application. In the past few days the question of privilege has been discussed in respect of a chance admission to a public assistance institution. A man had been discovered in Wrotham Park with injuries to the throat and wrist ; he said he had been lying there for four days. He was taken to the Wellhouse Hospital at Barnet where he remained for five weeks. He refused to give his name and, on his discharge (when the full cost of his maintenance was paid), the records described him as "unknown patient of no fixed abode." Police officers, who had questioned him in the hospital, were understood to have satisfied themselves of his identity, but it was no part of their duty to make any public announcement in this respect. The Hertfordshire public assistance committee asked the Barnet guardian's committee (the body responsible for the administration of the hospital as a poor-law institution) for further and better particulars on the ground that the hospital record was incomplete. The latter committee thereupon asked the medical superintendent, Dr. H. R. Segar, for the patient's name. Dr. Segar rightly declined to disclose the patient's secrets though all the ordinary details of the case which the county authority was entitled to know were, of course, forthcoming. The question of disclosure or non-disclosure by the medical superintendent was discussed at a meeting of the guardians' committee. The meeting was private in spite of the protests of one member who complained that the chairman was gagging them. The committee decided by 10 votes to 7 that it was not in the public interest that a doctor should violate professional confidence. This was not a case of compelling a medical witness to answer a question in a court of law. Dr. Segar, of course, has duties as an officer of the local authority. If the body which employs him took the view that his respect for professional secrecy was a breach of his duty to his employers, legal issues might arise over the possible termination of his employment. A local authority, however, which pressed matters to extremes would still have to find a medical practitioner to replace him. The Barnet guardians' committee has happily stood firm for the principle of non-disclosure. This principle is in the public interest ; secrecy is not preserved for the sake of the doctor but for the sake of his patients. It does not appear that knowledge of the name of this mysterious patient is of any supreme public importance. If there is any suspicion of a criminal element in the patient's injuries, that is a matter for the police authorities and has already been investigated to their satisfaction. The sole question for the medical practitioner in the Barnet case was whether the information about the name had this action in rowing or walking upstairs, the chief function of the quadriceps is to prevent the knee from bending too much in walking.

It is the tone of a muscle which is the important factor; tone does not depend on the motor nerves, but possibly on the sympathetic system, and it can be maintained for hours with very little metabolic activity in the muscle. With the adoption of the upright posture the tone of muscles had to be employed to prevent the knees, spine, and arches of the feet from collapsing, and the postural activity of the whole of the human body depends upon it. When a patient sprains his knee the quadriceps wastes, and if, when the joint itself has recovered, he is left with deficient action of the quadriceps, that knee will be undependable and will let him down. It is true that patients who have suffered from infantile paralysis may learn to walk well with a wasted quadriceps, but they do it by developing certain tricks of gait—by leaning forward on a stiff knee in walking—and not by walking normally. Transplantation of muscles is seldom performed now because it has proved to be unsatisfactory. You may transplant the hamstrings to the lateral sides of the patella, but the patient is not grateful, for though he may be able to perform certain movements voluntarily from the functional point of view he is in statu quo. He can get the transplanted muscles to take on the voluntary functions of the quadriceps but they will never take on the function of tone which is essential to the dependable knee. If both knees are injured and the posterior nerve-roots supplying them are divided on one side, the knee will waste on the side on which the nerves are undivided while the knee on the other side will not. There must, then, be a reflex mechanism which is responsible for wasting; possibly this is Nature's way of putting an injured joint at rest. Even if the injury is put right the knee will not recover from the patient's point of view until the quadriceps has recovered its normal size and tone.

When trying to re-develop the quadriceps we must begin by improving the general health, because the strength of the nerve impulses reaching a muscle depends on the general condition of the patient. Massage is an expensive luxury and cannot replace active use of a muscle in the restoration of function. Swedish exercises will not serve to develop tone; this can be achieved by exercises on the lines of operatic dancing—a posture being first assumed and then maintained for a time. We cannot educate a muscle any more than we can educate a liver or a bone, but we can educate the nervous mechanism on which its activity depends and the first thing to do after curing any disability of the knee is to make sure that the quadriceps is equal to that on the other leg.

A common form of trouble in the knee is due to injury of a semilunar cartilage. Often the original injury is trivial—simply a split or a tear of the anterior end of the internal cartilage associated with little pain and no bleeding. But the broken strip may not heal up; it forms a flap which, at a second accident, gets wedged between the tibia and the condyle of the femur; the internal lateral ligament suffers strain and there is considerable pain. Before operation is undertaken for this condition, however, five indications should be present:—

1. There should have been more than one attack.
2. A history of swelling must have been obtained. If there has been nipping of a portion of cartilage the patient will not have escaped without some synovitis.
3. The internal lateral ligament will have been stretched and there will be some lateral movement of the knee when the leg is straight.
4. One thigh will be smaller than the other.
5. The presence of a loose body in the joint must be excluded by X ray examination, as such bodies can be responsible for the same symptoms as an injured cartilage; and removal of the cartilage will not help the patient with a loose body in the joint.

The patient with an injury to an external cartilage has different symptoms. Nipping, locking, and synovitis do not occur, but he feels a scrunch as he extends the knee. If the examiner bends up the knee and rotates the tibia on the femur he will get a scrunch as the cartilage passes over the external condyle. The symptom may be disquieting to a patient who is a professional footballer, but he may be assured that his knee will not let him down in front of a bus.

Paget thought that loose bodies in joints were sequestra, but sequestra are dead, and loose bodies are living fragments of cartilage, possibly with a flake of bone attached, which continue to be nourished by the synovial fluid and to grow. They give signs, symptoms, and history similar to those obtained in cases of injury to a semilunar cartilage, but they are demonstrable by X ray.

A condition which calls for treatment may arise in growing girls as the pelvis gets wider. There may be some genu valgum, and when the quadriceps contracts there is a tendency for the patella to go outwards instead of remaining in its groove. In a bad case it will go right out, but in a moderate case it may become perched on the external condyle. The knee suddenly becomes fixed and cannot be extended, but if the knee is lifted forward the patella clicks back and an effusion into the joint follows; the history, therefore, resembles that of injury to a cartilage. The diagnosis is made by straightening the leg and pushing the unusually loose patella outwards; the knee is then flexed and the patella becomes perched on the condyle. The patient will recognise the pain as being the same as that she experiences when the knee "goes out." The patella can be fitted with a spring and pad to keep it in position and in most cases the condition recovers spontaneously as the patient grows.

In some patients there are bony excrescences round the upper end of the tibia and the lower end of the femur. These may give rise to a sudden snap similar to that observed in cases of nipped cartilage, followed by pain; there will be no effusion into the joint. The differential diagnosis can be made by the absence of swelling and by X ray examination.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

Surg. Comdr. J. S. Austin is placed on the retd. list, with the rank of Surg. Capt.

Surg. Lt.-Comdr. G. G. Newman to be Surg. Comdr.

Surg. Lt. (D) W. C. G. Ford to be Surg. Lt.-Comdr. (D).

T. F. Miles to be Surg. Lt.

ROYAL NAVAL VOLUNTEER RESERVE

Surg. Lt. R. L. Stubbs to be Surg. Lt.-Comdr.

ROYAL ARMY MEDICAL CORPS

Lt. S. W. Gabbe (temp. commn.) to be Capt.

M. J. Kohane, from a temp. commn., to be Lt. (on prob.).

TERRITORIAL ARMY

Capt. A. Topping to be Maj.

Supernumerary for service with O.T.C.—Lt. H. H. Kenshole to be Capt. T. H. Wilson (late Offr. Cadet Staff Serjt., Univ. of Lond. Contgt., Sen Div., O.T.C.) to be Lt. supern. for serv. with Univ. of Lond. Contgt., Med. Unit, Sen. Div., O.T.C.

INDIAN MEDICAL SERVICE

R. D. MacRae to be Lt. (on prob.).

Lt. D. L. Trant resigns his commn.

The undermentioned officers relinquish their temp. commns.: Capts. G. L. Puri, D. R. Malhotra, and B. K. Pal.

animals have since been incriminated, notably small rodents, the fox, and the porcupine. Dengue was another disease about which interesting discussions centred, and it would seem that, in addition to the mosquito campaign, preventive vaccination holds out prospects of success. A third Mediterranean disease coming under review was exanthematic Mediterranean fever, which is now known to be conveyed by a tick, the dog being the commonest host of the virus. The congress also dealt with the problem of rats on board ships and the chlorination of water. With regard to the former subject, Dr. Lutrario, former director-general of the Public Health Service of Italy, insisted that the most effective of all the remedies against rats is rat-proofing, and that if the campaign against rats on board ships is to be really effective, it must also be conducted relentlessly in ports and adjoining areas.

UNDULANT FEVER IN FRANCE

The work of Prof. Lisbonne, of Montpellier, is doing much to bring France into line with such countries as Denmark and the U.S.A. where a growing proportion of cases of pyrexia of unknown origin is being traced to Bang's bacillus and other bacilli of the same type. The undulant fever research centre at Montpellier has, in the course of a year and a half's research, discovered 28 cases, at least 20 of which have been verified by bacteriological examinations. Fourteen of these cases have been traced to *Br. melitensis*, and only six to *Br. abortus*. The geographical distribution of these cases is instructive. The abortus cases occurred in such areas as the Aisne and the Vosges, where the *Br. melitensis* of caprine and ovine origin is practically unknown. On the other hand, the melitensis cases occurred in the south and south-east of France. Prof. Lisbonne and his coöperator, Dr. L. F. Vidal, are inclined to consider *Br. abortus* as but slightly pathogenic to man, and they do not think that it will play any but a secondary rôle in human pathology in France. They have much greater respect for undulant fever due to *Br. melitensis* of bovine origin. They and other workers have reasons for believing that the goat and the sheep are passing on their infections to cattle, whence human beings become infected. They therefore disapprove of the practice of farmers in certain areas who let sheep and goats browse with cattle. It is by a process of transmission of infection from goat and sheep, through cattle, to man that they fear undulant fever may become endemic throughout France.

PUBLIC HEALTH SERVICES

Antituberculosis Work in Sheffield

THE campaign against tuberculosis in Sheffield continues to make progress when judged by mortality results. The death-rates in 1931 both from pulmonary and all forms of tuberculosis beat all previous records. Thus these rates per million were 673 and 818 respectively and may be compared with 1001 in 1209 for the first year of the last decade, and with 742 and 896 for England and Wales in 1931. Among the 18 towns in England and Wales with populations exceeding 200,000, Croydon was the only one which obtained more favourable results in 1931 than Sheffield—namely, 663 and 774. There were in Sheffield, during 1931, 232 male and 116 female deaths from the pulmonary form of the disease, so that if the death-rate for the population of over 265,000 females is calculated separately we obtain the rate of 438 per million, a truly remarkable figure if one is familiar with Sheffield's housing problem, or studies the activities of the corporation with regard to slum clearance and demolitions. The grinding industry is still a black spot, and among the 5000 grinders there were 36 deaths in 1931, as compared with an average of 32 for the previous seven years. Dr. John Rennie gives five factors as being the most important in securing the success obtained. (1) The complete coöperation of the medical profession; (2) the provision of adequate sanatorium and hospital accommodation; (3) the treatment of a large number of early cases discovered by the examination of suspects and contacts; (4) intensive work in the isolation of infectious cases; and, latterly, (5) the re-housing of families which include an infectious case of tuberculosis.

Some particulars which serve to illustrate Dr. Rennie's contention may be given from the report of Dr. H. Midgley Turner, the clinical tuberculosis officer.

Of 1515 new notifications in 1931 tubercle bacilli were found in the sputum of 21·2 per cent., and a large proportion of the remaining 78·8 per cent. were in the early and curable stage of the disease. The suspects sent to the dispensary for diagnosis numbered 2697 and 89 per cent. of the notified cases were sent to the dispensary prior to notification. The ultimate diagnosis of the suspects (who paid 12,846 visits to the dispensary) entailed much work and the use of observation beds and skiagrams and a similar statement applies to the examination of 3199 contacts from the homes of notified cases. The beds available for respiratory tuberculosis numbered 511, and a long waiting-list is a thing of the past.

Stress is laid on the importance of diagnosing and treating "minor" tuberculosis in children, and 72 places are reserved at the open-air schools for children selected by the tuberculosis officer. Tubercle bacilli were found in the sputum of seven children, whose names were therefore removed from the school registers and two of these have since died. Of the 1342 infectious cases on the register 51 per cent. had a separate bedroom and 26·4 per cent. a separate bed. Frequently a separate bed is available and not used and this is more common in the somewhat better residential districts than in the poorer districts of the east end.

The scheme for re-housing infected families on special terms began in 1928. Up to now 116 families, including 560 contacts, have been re-housed, of which 78 are still in the scheme, whilst in the case of 38 the special tenancies have been terminated owing to the removal of the need. In 17 cases the re-housed family remains on in a council house on an ordinary tenancy. Other authorities, it seems, are imitating this re-housing scheme.

Variety in School Medical Work

The Ministry of Health has indicated a method of whole-time appointment in which a medical officer would work under the local authority in general sanitary matters and under the county council in connexion with the health of school-children, child welfare, and tuberculosis. Under such a scheme the medical officer would not be so wholly occupied with school medical inspection as he is at present, and though medical inspection is not always dull work, it does as Dr. T. N. V. Potts puts it "run on a narrow gauge" and there are few who do not need the refreshment of occasional variation. It would be of benefit too, if, after a specified number of years of continuous service, a member of the staff could be granted study-leave for post-graduate courses approved by the Board of Education. Opportunity for clinical meetings would be beneficial if difficult cases could be collected and discussed. Hospitals under county management would, Dr. Potts thinks, came to him in confidential circumstances or not. Dr. Segar was in the best position to answer this question. The answer being presumably in the affirmative, he took the only course possible.

SCOTLAND

(FROM OUR OWN CORRESPONDENT)

THE TRAINING OF CHILDREN'S NURSES

Prof. Charles MacNeil, whose chair is "child life and health," in addressing the Edinburgh Women Citizens' Association the other day, said that his subject included the study of the body of the healthy child and those influences which maintained it in perfect health. Was there no way by which the women could receive benefit from this study? But before one could reach the mother herself, the education of the nurse was important. What was wanted was to bring up to something like the sick-nurse's level of efficiency the training of that other kind of nurse, the nurse of the healthy baby and the healthy child. In spite of the beginning made with mothercraft schools, Norland nurses, Princess Christian nurses, and child welfare nurses, Dr. MacNeil maintained that their training is still far behind that of the sick-nurse. The training should cover the diet of babies and little children, and the standards of health of an infant from birth up to the age of 5 years. Children's nurses should also be unerring in recognition of slight deviations from those standards. This was really an extensive programme of knowledge, he said; but it was ideal work for women, and no man could do it. There were only two places where such training could be given—the maternity hospitals, to a limited extent, and the child welfare centres. Child welfare nurses had greatly improved the homes of the poor. If he had his way he would increase their numbers in ten years at least tenfold, and give them far more responsible work.

EFFECTS OF ANXIETY

Dr. James Orr, St. Andrews, speaking on worry, said that nowadays a state of anxiety was accepted as a normal attitude, and he felt that this anxiety constituted the gravest menace to the physical and moral well-being of the nation. From an experience of over 30 years in the practice of general medicine, he could affirm, without fear of serious contradiction, that it was the most potent single cause of ill-health and disease in the civilised world at the present time. Day by day, in all classes of society and in every walk of life, one saw the damage done by anxiety with its attendant worry and apprehension. And the sad thing was that it was, in the main, unnecessary and ought to be very largely preventable. Whoever attempted to evade the inevitability of his environment was laying up for himself a miserable and anxious life, whereas he who was willing to meet the problems of his environment fairly and squarely and adapt himself to them would face the vicissitudes of his life with equanimity.

WOMEN'S WORK

At a women's conference at Dunblane Dr. Margaret Martin commented on the pamphlet on women's work lately issued by the International Labour Office, saying that it was inaccurate in its information and that the inaccuracies are bound to be prejudicial to the woman worker. A great deal of the nervous strain and debility she had discovered in working-class women was due, not to the work they did, but to the worry of not knowing where the next meal was coming from; there is more sickness due to unemployment and consequent under-nourishment than to overwork.

Dr. Joan Rose, speaking of the case of the pregnant woman in industrial work, said that employment during pregnancy is really a question for the individual. If the factory conditions are good and medical supervision adequate, it should be possible to deal with individuals instead of bringing in mass legislation to say that the pregnant woman is not fit for work. Any regulations should be permissive rather than obligatory.

THE REVOLUTION IN MEDICINE

At a recent meeting of the Scottish Association of Insurance Committees Prof. E. P. Cathcart, F.R.S., pointed out that faulty nutrition was until recently largely an evil of the towns, but the advent of motor vans had brought about a deterioration of the standard in the country. More costly and often inferior bought articles were steadily replacing the sound, if less decorative, home-made article, with a resultant deterioration in the standard of cookery. In the past the public health attack had been mainly directed against material things like water-supplies, sanitation, and slums. In the future, the main attack would be, indeed must be, on the habits and customs of men. Much could be done to reduce the incidence of severe illness even now if men were periodically examined, whether ill or not, and he was a firm believer in the scheme of examination adopted by certain big insurance companies in America. The great advance of medicine in the future would, he felt certain, be the accurate recognition of the first signs of the disturbance of normality. But man was an individual, and the old adage that it was impossible to teach an old dog new tricks was physiologically true. Hope lay in the young either of this or the next generation. Yet who could devise measures to enmesh the elusive mind of the adolescent female —on whom really depended the success of such attempts?

PARIS

(FROM OUR OWN CORRESPONDENT)

THE FIRST INTERNATIONAL CONGRESS ON MEDITERRANEAN HYGIENE

THE International Congress on Mediterranean Hygiene recently held at Marseilles under the presidency of Prof. Marchoux has yielded many interesting discussions on the diseases, old and new, more or less peculiar to this area. Prof. Marchoux's inaugural address was a concise but comprehensive survey of the history of tropical medicine and parasitology. The parasites which invade human beings in this area are of great variety. One of the latest to be discovered is the *Treponema hispanicum*, described in 1926 by Sadi de Buen, who presented the first report to the congress on this subject. The disease it provokes, Hispano-African spirochætosis, is most troublesome, if not fatal. This recurrent Spanish fever lasts a month or longer, with five or more remissions. The first bout of fever usually continues for three to eight days, and is followed by an apyrexial period of four to six days. The second attack seldom lasts as long as the first. Spontaneous recovery is the rule, and treatment has hitherto proved incapable of shortening the disease. The virus is transmitted by the tick *Ornithodorus erraticus*. The first animal convicted of acting as a host was the pig, and several other

CORRESPONDENCE

TAXATION OF COD-LIVER OIL

To the Editor of THE LANCET

SIR,—The possibility of a rise in the price of cod-liver oil as a result of the Ottawa proposals must arouse some anxiety in the minds of all who are concerned with the welfare of little children, especially those of the poorer class. Cod-liver oil has a value in early life which cannot easily be replaced—unless indeed any adequate supply can be obtained of other fish-liver oils which have similar properties; that there are such is known, and I have myself experimented with them in the treatment of rickets. The oil of *Gadus morrhua* is at present the one in common use, and the curtailment of its availability would be a misfortune for children. The various proprietary preparations assiduously advertised as concentrated vitamins, and some of them as a sort of multum-in-parvo substitute for cod-liver oil, besides being far more costly than the oil itself, lack certain properties which are particularly valuable in that oil, for it is not only as a vitamin-purveyor, but also as an oil with other valuable characteristics of its own that cod-liver oil is of use.

For those whose circumstances make a liberal use of eggs and milk and cream a simple matter, cod-liver oil is unnecessary, but for the poorly fed, who cannot obtain these foods in any adequate quantity, cod-liver oil is of very great value, and it would be a bad day for the children when the price of cod-liver oil rose sufficiently to prevent its use for every child who is needing it—and there are many.

I am, Sir, yours faithfully,
G. F. STILL.

Queen Anne-street, W., Oct. 14th, 1932.

To the Editor of THE LANCET

SIR,—In the Oliver-Sharpey lectures for 1932 I have already expressed a view in entire agreement with the substance of your article on the taxation of cod-liver oil, that "for infants and growing children it is probable that a small daily ration of cod-liver oil, given especially during the winter months, is the surest and most economical procedure . . . to obtain the necessary supply of antirachitic vitamin for the poorer section of the population."

In this country, in winter, no antirachitic effect can be derived from the sunshine, which is not only very limited in amount, but also depleted of those ultra-violet rays of short wave-length, which possess antirachitic properties. Reliance for a supply of vitamin D must, therefore, be placed on diet. The diet of the poorer classes is, of necessity, deficient in this vitamin, which is found only in the relatively expensive foodstuffs; eggs, milk, butter, and other animal fats. In winter moreover the amount contained in these foods is seriously diminished, and the relative richness of cod-liver oil makes even a small ration of the greatest value.

It is evident, therefore, that any steps which may raise the price and lower the consumption of cod-liver oil cannot fail, especially in winter, to have a deleterious effect on the health of the population, involving particularly the well-being of the children of the poorer classes.

I am, Sir, yours faithfully,
HARRIETTE CHICK.

Lister Institute of Preventive Medicine,
Chelsea Bridge-road, Oct. 17th, 1932.

⁂ The increasing use of cod-liver oil in the feeding of stock animals is also of importance to human nutrition, because it tends to raise the vitamin-D content of the milk, butter and animal fats. As Dr. Chick points out, this is seriously reduced during the winter, when sunshine is scarce.—ED. L.

MARMITE IN PERNICIOUS ANÆMIA

To the Editor of THE LANCET

SIR,—I have read with great interest Dr. Goodall's paper (Oct. 8th) on the treatment of pernicious anæmia by marmite. In the opening paragraphs he refers to a previous publication of mine,[1] in which I suggested that the anti-anæmic factor of liver and vitamin B are not identical substances. As this is still my opinion, I should be obliged if you would publish the following observations.

Three cases of pernicious anæmia in the relapse stage were treated by Dr. Goodall with large doses of marmite (half an ounce three times a day), and responded with reticulocyte crises and rises in the blood level. This is not perhaps the place for me to discuss whether the height of the reticulocyte crises and the speed of blood regeneration in these cases were comparable to that obtained by the use of active liver preparations. In my previous publication I reported that one case of pernicious anæmia responded to marmite but others failed to do so, while they subsequently responded satisfactorily to oral or parenteral liver therapy. Since the publication of this paper I have treated with marmite three other cases of pernicious anæmia in the relapse stage; one responded and two failed. Some observations on these cases would appear to be of interest.

About a year ago there were two cases of pernicious anæmia in my wards at the same time whose blood counts were practically identical (just over one million) and whose gastric contents were completely deficient both in ferments and hydrochloric acid, even after histamine injection. They were both placed on marmite, ʒii. three times a day. One responded with a typical reticulocyte crisis and a rise in the blood level to normal, and has since remained normal on ʒi. of marmite three times a day. The other completely failed to show any response, and after three weeks' treatment was given a fish-liver extract made in my department, which produced a 30 per cent. reticulocyte crisis within a week, and a threefold rise in the blood level in three weeks. The only point of difference between these two cases which I could discover was that the one which responded to marmite had been anæmic for less than six months, while the other had been anæmic for three years.

That the majority of patients suffering from Addisonian anæmia fail to respond to vitamin-B preparations is clearly shown by the carefully controlled series of cases recently published by M. B. Strauss and W. B. Castle,[2] in which the administration of 12 g. daily of an autolysed yeast product was entirely ineffective. When this product was incubated with normal gastric juice it was found to be active. The present position in regard to vitamin B in the treatment of macrocytic anæmias may be summarised as follows: It is efficacious in tropical macrocytic anæmia, in cœliac disease, in many cases of sprue, and in some cases of Addisonian anæmia. In the first three conditions the intrinsic factor of Castle is produced by the stomach in normal or subnormal provide an excellent complement to existing services. He writes :—

---

[1] THE LANCET, 1931, ii., 1395.

[2] Ibid., July 16th, p. 111.

> "A class of child of particular interest is the one who is subnormal in health without suffering from any complaint to which a label can be attached. Even with the help of information given by health visitors and parents, the diagnosis is very difficult—mostly guesswork based on probability—and everyone faced with such a difficulty wishes for an opportunity of observation such as can only be provided by hospital treatment. Such facilities would form an ideal opportunity for gaining accurate information, and clinical meetings and free discussions would be a real help towards accuracy of diagnosis. General hospitals are too busy and their honorary staffs could not be expected to hold clinical meetings and lead the discussions on such cases unless they hold official positions as consultant medical officers to the education committee. On the other hand general hospitals managed and staffed by officials of the county would amply supply this desideratum."

Another method of increasing the interest of school doctors in their work is the encouragement and organisation of research into problems that are specially found in the work of this service, and whose elucidation is of value to the medical profession as a whole. This method is exemplified in the West Riding report itself by a special investigation into the causes of blepharitis by Dr. R. L. H. Davy, who in 64 cases found the causative factors to be : eczema or dermatitis in 17 ; delicacy with enlarged glands or tonsils or carious teeth in 23 ; defective vision in 26. Doubtless refractive errors were present in a larger number than this, for she remarks how often the chronic cases did not yield to yellow-oxide ointment until a little atropine was added to remove the strain of accommodation. And in a study by Mr. J. Mackay, L.D.S., of the effect on the teeth of biscuits given with milk. Caries, he says, is produced because the milk gums down the biscuit to the buccal convexity of the molars, the cheek assisting to keep the plaque adherent. The resulting cavity though small is troublesome to fill owing to its inaccessible position.

Growth of Subnormal Children

Mentally subnormal children are subnormal in height, weight, and growth. Practically all authorities agree on this. A passage in the report of the chief medical officer of the Board of Education for 1929 runs : "It should be remembered that mental defects of all kinds and degrees bear a closer relation to physical and social conditions than is often assumed." But Dr. Leslie Cronk tells us this does not hold for the special school at Larkhills, Hants, where systematic measurements have been made. Figures given in his report are these :—

Age-group.	Height of M.D.'s.	Standard height.	Weight of M.D.'s.	Standard weight.
15 to 16	61·82	61·8	106·7	99·3
14 to 15	59·38	58·0	93·4	86·1
13 to 14	57·15	56·2	83·2	76·5
12 to 13	55·62	55·0	75·79	71·6
11 to 12	53·75	52·7	70·04	64·6
10 to 11	52·20	51·3	66·43	59·6
9 to 10	51·51	49·2	63·82	54·8
8 to 9	49·84	47·0	59·8	51·0

The standard heights and weights given are the means of the Anthropometrical Committee (1927). Dr. Cronk adds the figures of the Board of Education (1913) and of Dr. Corry Mann (1926) and the measurements of the mentally defective boys at Larkhills are much superior to them all at every age.

The percentage annual increments of growth were for height :—

	14–13	*13–14*	*12–13*	*11–12*	*10–11*
M.D.'s ..	3·99	3·83	3·67	4·06	4·18
Normals ..	4·43	3·73	2·17	3·59	4·21

and for weight :—

	14–13	*13–14*	*12–13*	*11–12*	*10–11*
M.D.'s ..	11·04	10·43	11·22	8·29	10·28
Normals ..	12·07	8·53	6·52	9·41	10·04

Normals being the increments given by the Board of Education.

The comparison is mostly in favour of the boys at Larkhills. The results are striking, although the numbers were small—not much over 50 in all—and the standards for both height and weight have tended to increase during the past five years. Larkhills is, however, a residential school where food and living conditions are excellent. Thus the results, though of considerable interest, do not prove that *under similar conditions* the mentally defective are up to the average stature of the population.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED OCT. 8TH, 1932

Notifications.—The following cases of infectious disease were notified during the week :—Small-pox, 17 (last week, 23) ; scarlet fever, 1934 ; diphtheria, 935 ; enteric fever, 62 ; acute pneumonia (primary or influenzal), 664 ; puerperal fever, 43 ; puerperal pyrexia, 94 ; cerebro-spinal fever, 29 ; acute poliomyelitis, 48 ; acute polio-encephalitis, 3 ; encephalitis lethargica, 14 ; dysentery, 18 ; ophthalmia neonatorum, 81. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on Oct. 11th–12th was as follows :—Small-pox, 44 under treatment, 4 under observation (last week 42 and 1 respectively) ; scarlet fever, 1625 ; diphtheria, 1603 ; enteric fever, 21 ; measles, 232 ; whooping-cough, 320 ; puerperal fever, 24 (plus 9 babies) ; encephalitis lethargica, 231 ; poliomyelitis, 6 ; "other diseases," 153. At St. Margaret's Hospital there were 19 babies (plus 6 mothers) with ophthalmia neonatorum.

Deaths.—In 117 great towns, including London, there was no death from small-pox or enteric fever, 6 (0) from measles, 4 (1) from scarlet fever, 15 (2) from whooping-cough, 30 (6) from diphtheria, 84 (19) from diarrhœa and enteritis under two years, and 31 (3) from influenza. The figures in parentheses are those for London itself.

The deaths from diarrhœa were still maintained, the highest figures being Liverpool 9, Leeds 6, Hull, Newcastle-on-Tyne, and Birmingham, each 4. Diphtheria accounted for 3 deaths at Hull.

The number of stillbirths notified during the week was 258 corresponding to a rate of 41 per 1000 total births), including 37 in London.

NURSES' HOME AT NORFOLK AND NORWICH HOSPITAL. On Saturday last the Queen opened the new nurses' home at this hospital. The building, which has cost £30,000, forms part of the Queen Alexandra Memorial Wing, and completes an extension scheme that has cost £160,000. It was stated that every parish in Norfolk and every street in Norwich had given to the fund, with the result that it was over-subscribed by £2000, which was used to pay for the fittings and furnishing. The money was handed to the Queen by 155 purse-bearers. The new four-storeyed building contains 170 rooms, of which 103 are bedrooms. Each bedroom measures 10 ft. by 8 ft., and for economy of space is fitted with a built-in wardrobe, consisting of hanging wardrobe, long mirror, cupboard, shelves, and writing table. On each floor there are two toilet rooms fitted with four fixed wash-basins, and four bathrooms, allowing one bath for every seven nurses. Also, there are a shampoo room, a boot room, and a small laundry. Fixed wash-basins, with hot and cold water-supply, are provided in the sisters' bedrooms on the first floor, and private sitting-rooms adjoin the bedrooms of the senior sisters. There is also a sisters' common room on this floor. On the ground floor is a large lecture hall with walls covered with sound-absorbing material, together with a "quiet room" for study.

yielded information concerning the constitution of the herds that enables us to accept Dr. Gloyne's finding without reserve. I raised my query in the hope that school medical officers would become articulate and inform us what their experience has been in the matter of milk schemes. I hope their silence does not indicate that the story is too tragic to tell.

I am, Sir, yours faithfully,

W. R. DUNSTAN,

Oct. 17th, 1932. M.O.H., Lewes, &c.

THE INCREASE IN ARSENIC-RESISTANT SYPHILIS

To the Editor of THE LANCET

SIR.—Since I have made a fairly complete—and I hope, a completely fair—criticism of Drake and Thomson's report which gave rise to this correspondence, in an article which will appear in a forthcoming number of the *British Journal of Dermatology and Syphilis,* I do not propose to continue the discussion in these columns. Everyone will surely homologate Dr. Semon's endorsement of Dr. Browdy's platitude that it is not syphilis but the patient that we have to treat. That is a postulate writ large upon every page of therapy. Although we may loosely talk of treating a disease, we really mean that we treat a person who is suffering from a disease, for a disease cannot exist apart from a person. The two are inseparable. In syphilis there are always the two elements—the patient and the parasite. The former has to be treated, the latter has to be attacked; and the attack must not damage the patient either by its intensity or by its inefficiency. I realise that I am perpetrating further platitudes, but I am constrained to do so because I detect a suggestion—which is of course utterly wrong—that I am advocating some hideous form of mechanical standardisation. All I appeal for is adequacy, and the full and rational utilisation of our modern resources against syphilis.

I am, Sir, yours faithfully,

E. TYTLER BURKE.

Municipal Clinic, Salford, Oct. 15th, 1932.

PANEL AND CONTRACT PRACTICE

The Voice of the Panel

As we go to press, the annual conference of representatives of local medical and panel committees is being held at B.M.A. House, and it may be worth while to consider for a moment how the ordinary insurance practitioner can get his ideas brought before the appropriate tribunal. The full title of the conference quoted above might suggest that there were two sorts of committees whose representatives were conferring. This may be so in one or two areas, but in the great majority the personnel of the panel committee and of the local medical committee is now the same. When the first N.H.I. Act came into force it was thought advisable to have a committee to represent those doctors who were under contract with an insurance committee. This "panel" committee, to the extent of three parts at least, consists of insurance practitioners elected for two or three years by the direct votes of insurance practitioners in the committee's area. The voting is taken by post or at a polling-station where a meeting for the purpose is held, and is often addressed by members of the outgoing committee or from other areas. It is pitiful to see how badly these meetings are attended and what indifference is shown in the election of a man to voice the ideas of his constituency.

The work of the panel committee is honorary, some allowance at times being made for subsistence and train fares. Possibly more interest would be taken in the work if those who undertook it were remunerated out of the pockets of the large indifferent majority. The costs however do come out of the insurance practitioner's pocket, whether by a tax on the practitioners' fund for the area or by a special voluntary levy. Panel committees now do so much statutory work on behalf of the Government, such as investigating excessive prescribing or certification, that it hardly seems fair for the expenses to be borne entirely by medical practitioners working under the Act without any help from (say) the Ministry of Health. To go back to the first Insurance Act, the Government felt that whilst they would undoubtedly want to know the views of insurance practitioners working the Act in a particular area, they might also want to know the views of all doctors in that area, and so the "local medical" committee was set up representative of all doctors in the area, questions which affected the profession as a whole being referred to it. In the early days when there was still much opposition to the Act it was thought that the panel committee and the local medical committee might be quite different bodies. Now the same doctors usually act for both committees.

There is a panel committee to correspond with every insurance committee, and the latter has to consult with the panel committee when it wishes to do anything which involves a change in the terms of service or the conditions of practice. The panel committee, elected as stated above, sends representatives to the medical service subcommittee of the insurance committee, in the same number as the insured person's representatives. It is also represented on the insurance committee itself, and on its allocation subcommittee which deals with insured persons who fail to choose a doctor within a certain time. The panel committee, or a group of them depending on the size of the area, sends representatives to the Insurance Acts Committee, which is the main medical committee of the whole service; to this body the Minister refers matters for discussion and decision, knowing that it represents insurance practitioners and that its decisions will in all probability be carried out. The I.A.C. consists of able men with keen perception and alert intellect, all familiar with the trials and pitfalls of insurance practice. It meets in London every two or three months and draws up a report of its work which it presents through its chairman to the panel conference. To this conference each panel committee sends one or more representatives, depending upon the size and constitution of the committee. The conference decides matters not sufficiently urgent to require immediate action by the I.A.C., but upon which the I.A.C. may have come to some decision itself. Thus at the conference this week the subject of anæsthetics will have been discussed and directions given to the Insurance Acts Committee as to how they are to negotiate on the subject with the Ministry. Membership of the I.A.C. entitles attendance at the conference, but not the right to vote. Representatives of the panel committee at this conference will hear the other man's point of view and obtain a broader outlook on matters than those who stay at home. Service on a panel committee is apt to become dull and uninteresting amounts; in pernicious anæmia it is usually not produced at all. It must be remembered that the power to secrete this intrinsic factor is not suddenly lost, but gradually decreases. If excess of the extrinsic factor be given in a concentrated form, a response to treatment will result provided any intrinsic factor is present. Vitamin-B preparations apparently contain the extrinsic factor in a concentrated form. There is evidence to show that during a remission an improvement in the secretion of the intrinsic factor may occur, and it may possibly be for this reason that the administration of concentrated extrinsic factor, as in marmite, may be of value. Whether the extrinsic factor is vitamin B or some amino-acid present in the concentrate, and which is necessary for blood formation, is a question to which no definite answer can at present be given. Castle believes that the former is the correct explanation, but in view of the large dosage of the preparations required, the possibility of the latter being responsible cannot be neglected. If marmite (vitamin B) is the extrinsic factor in a concentrated form, then it cannot be the same as the anti-anæmic principle of liver, since this is the product formed in the stomach by the interaction of the extrinsic and intrinsic factors, and subsequently stored in the liver. Since many cases of pernicious anæmia in the relapse stage fail to respond to vitamin-B preparations, it would be very unwise at the present stage to suggest that marmite can replace liver and hog's stomach preparations in the treatment of Addisonian pernicious anæmia.

I am, Sir, yours faithfully,

STANLEY DAVIDSON.

University of Aberdeen, Oct. 17th, 1932.

PRE-NURSING COURSES

To the Editor of THE LANCET

SIR,—I am no longer in active work, and cannot claim to be in touch with the needs of the nursing world of to-day, but I have read with great interest parts of the Final Report of THE LANCET Commission on the subject. It seems to me that the establishing of centres for the teaching of elementary anatomy, physiology, and hygiene would be very costly. If the authorities of existing university medical colleges could be induced to form classes for women on the lines of enclosed syllabus, it would leave the nurses' training schools free to deal with clinical teaching only—i.e., if these schools and the State examiners would agree to accept the university certificates as sufficient evidence of the fitness of a pupil to continue her studies as a professional nurse, thus maintaining a one-portal system. There would require to be a very stringent rule as to the length of time allowed between the taking of said certificates and the entering of a nurses' training school.

The clinical teaching could then be carried on with a degree of relief for all concerned. At present the requirements of a sister tutor are such as to require an M.B. at least to meet them.

I am, Sir, yours faithfully,

Edinburgh, Oct. 11th, 1932. REBECCA STRONG.

*** At the time when the Final Report of THE LANCET Commission was issued it was decided to publish no comments on its findings, since the selection of some letters from the many received would have proved an invidious task. An exception is here made in view of Mrs. Strong's unique contribution to nursing history. Now in her ninetieth year, she entered in 1867 the Nightingale Training School at St. Thomas's Hospital, which had been founded in 1860. On completion of her training she went as one of six nurses to the Royal Hants County Hospital, and a year later formed one of the first batch of Protestant "sisters" to be employed in the British army. In 1874 Mrs. Strong became matron of the Royal Infirmary, Dundee, and in 1879 of the Royal Infirmary, Glasgow. Resigning in 1885 because of her inability to secure better accommodation for her nurses, she was reappointed six years afterwards, and organised in January, 1893, a pre-nursing course, consisting of 12 lectures each in anatomy, physiology, and hygiene, of which the syllabus, to which she refers above, coincides to a remarkable extent with modern requirements. Her endorsement of the principles which form the basis of Recommendations XL. to XLIII. of THE LANCET Commission on Nursing are timely, in view of the differences of opinion with which these recommendations have been met in the nursing profession. (See *Nursing Times*, Oct. 15th, pp. 1056 and 1062, and *Nursing Mirror*, Oct. 15th, pp. 42 and 52.) In this connexion a letter from the president of the Association of Head Mistresses in the *Times* of Oct. 14th is of moment. After referring to the widespread interest created by the report of THE LANCET Commission, Miss Strudwick continues:

> "The Executive Committee of the Association of Head Mistresses, at a meeting held on Oct. 8th, after a discussion upon the report, passed a resolution warmly endorsing the recommendation made in it that the Preliminary State Examination for Nurses should be divided into two parts. The object of this suggestion is to make it possible, though not compulsory, for the intending nurse to take the first part, consisting of anatomy, physiology, and hygiene, before she enters hospital. We feel convinced that adequate preparation in these subjects could be given in many of our schools; it is already being given in some. If the girl could master the elements of these subjects in advance it would greatly lessen the strain of her first year in the hospital, when, after a long day's work in the wards, she has to study them in the evenings.
>
> We note with satisfaction that the General Nursing Council for Scotland has already passed a resolution in favour of this change, and wish to record our hope that the General Nursing Council for England and Wales will also decide to approve of it, since we believe that its adoption will attract to hospital service a large number of suitable candidates from the higher forms of our schools."

This statement will encourage members of the nursing profession who are pressing for such a change.—ED. L.

USE OF THE WORD "HYPODERMIC"

To the Editor of THE LANCET

SIR,—Medical men confine the use of the word "hypodermic" to drugs which may be given subcutaneously, but druggists apply it to any drug which is suitable for use with a hypodermic syringe. Drugs such as tartar emetic, which can be given only intravenously, have even been included in a list of preparations for hypodermic injection. To avoid confusion the term "hypodermic" should, I think, be confined to drugs which may be administered just under the skin, and drugs such as tartar emetic should be designated "For intravenous injection only." I am, Sir, yours faithfully,

Durban, Sept. 23rd, 1932. F. G. CAWSTON, M.D.

SAFE MILK

To the Editor of THE LANCET

SIR,—I see that my query in the *Times* as to whether Grade A (T.T.) milk, as supplied to the schools, is altogether free from risk has been commented on in your correspondence columns. Mr. D. S. Rabagliati, in what I take to be an attempt at defensive pleading, appears to me to turn King's evidence and to have yielded information concerning the constitution of the herds that enables us to accept Dr. Gloyne's finding without reserve. I raised my query in the hope that school medical officers would become articulate and inform us what their experience has been in the matter of milk schemes. I hope their silence does not indicate that the story is too tragic to tell.

I am, Sir, yours faithfully,

PANEL AND CONTRACT PRACTICE

The Voice of the Panel

As we go to press, the annual conference of representatives of local medical and panel committees is being held at B.M.A. House, and it may be worth while to consider for a moment how the ordinary insurance practitioner can get his ideas brought before the appropriate tribunal. The full title of the conference quoted above might suggest that there were two sorts of committees whose representatives were conferring. This may be so in one or two areas, but in the great majority the personnel of the panel committee and of the local medical committee is now the same. When the first N.H.I. Act came into force it was thought advisable to have a committee to represent those doctors who were under contract with an insurance committee. This "panel" committee, to the extent of three parts at least, consists of insurance practitioners elected for two or three years by the direct votes of insurance practitioners in the committee's area. The voting is taken by post or at a polling-station where a meeting for the purpose is held, and is often addressed by members of the outgoing committee or from other areas. It is pitiful to see how badly these meetings are attended and what indifference is shown in the election of a man to voice the ideas of his constituency.

The work of the panel committee is honorary, some allowance at times being made for subsistence and train fares. Possibly more interest would be taken in the work if those who undertook it were remunerated out of the pockets of the large indifferent majority. The costs however do come out of the insurance practitioner's pocket, whether by a tax on the practitioners' fund for the area or by a special voluntary levy. Panel committees now do so much statutory work on behalf of the Government, such as investigating excessive prescribing or certification, that it hardly seems fair for the expenses to be borne entirely by medical practitioners working under the Act without any help from (say) the Ministry of Health. To go back to the first Insurance Act, the Government felt that whilst they would undoubtedly want to know the views of insurance practitioners working the Act in a particular area, they might also want to know the views of all doctors in that area, and so the "local medical" committee was set up representative of all doctors in the area, questions which affected the profession as a whole being referred to it. In the early days when there was still much opposition to the Act it was thought that the panel committee and the local medical committee might be quite different bodies. Now the same doctors usually act for both committees.

There is a panel committee to correspond with every insurance committee, and the latter has to consult with the panel committee when it wishes to do anything which involves a change in the terms of service or the conditions of practice. The panel committee, elected as stated above, sends representatives to the medical service subcommittee of the insurance committee, in the same number as the insured person's representatives. It is also represented on the insurance committee itself, and on its allocation subcommittee which deals with insured persons who fail to choose a doctor within a certain time. The panel committee, or a group of them depending on the size of the area, sends representatives to the Insurance Acts Committee, which is the main medical committee of the whole service; to this body the Minister refers matters for discussion and decision, knowing that it represents insurance practitioners and that its decisions will in all probability be carried out. The I.A.C. consists of able men with keen perception and alert intellect, all familiar with the trials and pitfalls of insurance practice. It meets in London every two or three months and draws up a report of its work which it presents through its chairman to the panel conference. To this conference each panel committee sends one or more representatives, depending upon the size and constitution of the committee. The conference decides matters not sufficiently urgent to require immediate action by the I.A.C., but upon which the I.A.C. may have come to some decision itself. Thus at the conference this week the subject of anæsthetics will have been discussed and directions given to the Insurance Acts Committee as to how they are to negotiate on the subject with the Ministry. Membership of the I.A.C. entitles attendance at the conference, but not the right to vote. Representatives of the panel committee at this conference will hear the other man's point of view and obtain a broader outlook on matters than those who stay at home. Service on a panel committee is apt to become dull and uninteresting amounts; in pernicious anæmia it is usually not produced at all. It must be remembered that the power to secrete this intrinsic factor is not suddenly lost, but gradually decreases. If excess of the extrinsic factor be given in a concentrated form, a response to treatment will result provided any intrinsic factor is present. Vitamin-B preparations apparently contain the extrinsic factor in a concentrated form. There is evidence to show that during a remission an improvement in the secretion of the intrinsic factor may occur, and it may possibly be for this reason that the administration of concentrated extrinsic factor, as in marmite, may be of value. Whether the extrinsic factor is vitamin B or some amino-acid present in the concentrate, and which is necessary for blood formation, is a question to which no definite answer can at present be given. Castle believes that the former is the correct explanation, but in view of the large dosage of the preparations required, the possibility of the latter being responsible cannot be neglected. If marmite (vitamin B) is the extrinsic factor in a concentrated form, then it cannot be the same as the anti-anæmic principle of liver, since this is the product formed in the stomach by the interaction of the extrinsic and intrinsic factors, and subsequently stored in the liver. Since many cases of pernicious anæmia in the relapse stage fail to respond to vitamin-B preparations, it would be very unwise at the present stage to suggest that marmite can replace liver and hog's stomach preparations in the treatment of Addisonian pernicious anæmia.

I am, Sir, yours faithfully,

STANLEY DAVIDSON.

University of Aberdeen, Oct. 17th, 1932.

PRE-NURSING COURSES

To the Editor of THE LANCET

SIR,—I am no longer in active work, and cannot claim to be in touch with the needs of the nursing world of to-day, but I have read with great interest parts of the Final Report of THE LANCET Commission on the subject. It seems to me that the establishing of centres for the teaching of elementary anatomy, physiology, and hygiene would be very costly. If the authorities of existing university medical colleges could be induced to form classes for women on the lines of enclosed syllabus, it would leave the nurses' training schools free to deal with clinical teaching only—i.e., if these schools and the State examiners would agree to accept the university certificates as sufficient evidence of the fitness of a pupil to continue her studies as a professional nurse, thus maintaining a one-portal system. There would require to be a very stringent rule as to the length of time allowed between the taking of said certificates and the entering of a nurses' training school.

The clinical teaching could then be carried on with a degree of relief for all concerned. At present the requirements of a sister tutor are such as to require an M.B. at least to meet them.

I am, Sir, yours faithfully,

Edinburgh, Oct. 11th, 1932. REBECCA STRONG.

*** At the time when the Final Report of THE LANCET Commission was issued it was decided to publish no comments on its findings, since the selection of some letters from the many received would have proved an invidious task. An exception is here made in view of Mrs. Strong's unique contribution to nursing history. Now in her ninetieth year, she entered in 1867 the Nightingale Training School at St. Thomas's Hospital, which had been founded in 1860. On completion of her training she went as one of six nurses to the Royal Hants County Hospital, and a year later formed one of the first batch of Protestant "sisters" to be employed in the British army. In 1874 Mrs. Strong became matron of the Royal Infirmary, Dundee, and in 1879 of the Royal Infirmary, Glasgow. Resigning in 1885 because of her inability to secure better accommodation for her nurses, she was reappointed six years afterwards, and organised in January, 1893, a pre-nursing course, consisting of 12 lectures each in anatomy, physiology, and hygiene, of which the syllabus, to which she refers above, coincides to a remarkable extent with modern requirements. Her endorsement of the principles which form the basis of Recommendations XL. to XLIII. of THE LANCET Commission on Nursing are timely, in view of the differences of opinion with which these recommendations have been met in the nursing profession. (See *Nursing Times*, Oct. 15th, pp. 1056 and 1062, and *Nursing Mirror*, Oct. 15th, pp. 42 and 52.) In this connexion a letter from the president of the Association of Head Mistresses in the *Times* of Oct. 14th is of moment. After referring to the widespread interest created by the report of THE LANCET Commission, Miss Strudwick continues:

> "The Executive Committee of the Association of Head Mistresses, at a meeting held on Oct. 8th, after a discussion upon the report, passed a resolution warmly endorsing the recommendation made in it that the Preliminary State Examination for Nurses should be divided into two parts. The object of this suggestion is to make it possible, though not compulsory, for the intending nurse to take the first part, consisting of anatomy, physiology, and hygiene, before she enters hospital. We feel convinced that adequate preparation in these subjects could be given in many of our schools; it is already being given in some. If the girl could master the elements of these subjects in advance it would greatly lessen the strain of her first year in the hospital, when, after a long day's work in the wards, she has to study them in the evenings.
>
> We note with satisfaction that the General Nursing Council for Scotland has already passed a resolution in favour of this change, and wish to record our hope that the General Nursing Council for England and Wales will also decide to approve of it, since we believe that its adoption will attract to hospital service a large number of suitable candidates from the higher forms of our schools."

This statement will encourage members of the nursing profession who are pressing for such a change.—ED. L.

USE OF THE WORD "HYPODERMIC"

To the Editor of THE LANCET

SIR,—Medical men confine the use of the word "hypodermic" to drugs which may be given subcutaneously, but druggists apply it to any drug which is suitable for use with a hypodermic syringe. Drugs such as tartar emetic, which can be given only intravenously, have even been included in a list of preparations for hypodermic injection. To avoid confusion the term "hypodermic" should, I think, be confined to drugs which may be administered just under the skin, and drugs such as tartar emetic should be designated "For intravenous injection only." I am, Sir, yours faithfully,

Durban, Sept. 23rd, 1932. F. G. CAWSTON, M.D.

SAFE MILK

To the Editor of THE LANCET

SIR,—I see that my query in the *Times* as to whether Grade A (T.T.) milk, as supplied to the schools, is altogether free from risk has been commented on in your correspondence columns. Mr. D. S. Rabagliati, in what I take to be an attempt at defensive pleading, appears to me to turn King's evidence and to have

MEDICAL NEWS

University of Oxford

On Oct. 13th the degree of Bachelor of Medicine was conferred on A. W. D. Leishman and O. J. Vaughan Jackson.

University of Manchester

At recent examinations the following candidates were successful:—

D.P.H.

Part II.—Charlotte E. Forsyth and V. A. Newton.

University of Dublin

At recent examinations in the School of Physic, Trinity College, the following candidates were successful:—

M.D.

W. E. Hutchinson and T. F. M. Woods.

FINAL MEDICAL EXAMINATION FOR M.B., B.CH.

Part I.—Old regulations: H. L. Connor, C. L. Greer, B. E. W. Aldwell, and P. St. G. Robinson.

New regulations: Marie J. S. O'Toole, W. G. B. Halliden, A. F. J. Delany, J. F. Harbinson, A. E. Fannin, A. R. S. Jessop, R. C. Tyner, H. M. Glover, Doris E. Morton, and D. J. O'Shaughnessy.

DIPLOMA IN GYNÆCOLOGY AND OBSTETRICS

Joseph Borg and Anis El S. El Khishin.

Royal College of Surgeons of England

A quarterly meeting of the council was held on Oct. 13th, with Sir Holburt Waring, the president, in the chair.

Diplomas of Fellowship were granted to George Frederick Langley (Bristol) and William Eric Archer Hughes-Jones (Melbourne and St. Bartholomew's), and a diploma of Membership was granted to H. F. Moseley (McGill and St. Thomas's).

It was announced that Sir Buckston Browne had now completed his gift of £100,000 for building and endowing the Surgical Research Farm at Downe, Kent. Sir Henry Wellcome was admitted an honorary fellow of the College, and Mr. Herbert Alstead, late of Wigan Grammar School, was admitted the third Macloghlin scholar.

The council passed a resolution of condolence on the death of Sir Charters Symonds, past vice-president of the College.

The three museum demonstrations by Sir Arthur Keith, arranged for Fridays, Oct. 21st and 28t hand Nov. 4th, have been postponed.

The Meath Hospital

Our Dublin Correspondent writes:—The Meath Hospital is the only one of the Dublin clinical hospitals which preserves the old custom of opening the session with an address to the students. This duty was performed last week by Sir John Moore, who has now entered on his 58th year of service as a physician to the hospital, having been appointed to succeed William Stokes in 1875. The subject of his address was the Medical Student at Hospital, and he devoted himself mainly to a discussion of the responsibility attaching to the profession of medicine. On the evening of the following day, Sir John presided at a dinner at the Gresham Hotel, at which some 70 present and past students of the hospital and their guests attended. Among the guests were the president of the Royal College of Physicians of Ireland, and the president of the Royal College of Surgeons in Ireland.

Society for Relief of Widows and Orphans of Medical Men

At a quarterly meeting of the court of directors held on Oct. 12th, Mr. V. Warren Low, the president, being in the chair, the death was reported of a widow who had been in receipt of grants since 1918. Her late husband had paid in subscriptions £52 10*s.*, the maximum amount that any member pays. His widow received a total sum in grants of £1100. The death was reported of three members, and application for relief from their widows. They were each granted £50 per annum from the ordinary funds, two, being over 65 years of age, £25 per annum from the Brickwell Fund each, and the third, being under 65, a grant of £10 per annum from the same fund. A sum of £176 15*s.* was voted as special grants to widows, to enable them to continue with the education of their children, who had reached the age of 16, at which age the ordinary grants cease. It was decided to make a Christmas present of £15 to each widow over 75, £10 to each widow under that age, and £10 to each orphan—at a cost of £640. Three new members were elected. Membership is open to any registered medical practitioner, who at the time of his election is resident within a 20-mile radius of Charing Cross. Particulars from the secretary, 11, Chandos-street, London, W.1.

Bio-Chemical Society

The meeting of this society is being held at 4 P.M. to-day, Friday, Oct. 21st, at the National Institute for Medical Research, Hampstead.

St. Peter's Hospital for Stone

A post-graduate course will be held in the pathology department of this hospital, 10, Henrietta-street, London, W.C.2, at 3 P.M. on Wednesdays, from Nov. 2nd to Dec. 21st. A full syllabus may be had from the secretary of the hospital.

Donations and Bequests

The late Mr. Benjamin Hopkin Morris, of Chiswick, left £1000 to Merthyr Tydfil Hospital in memory of his mother, for the endowment of a "Mary Morris" Bed (unless provided in his lifetime), and £1000 to the West London Hospital for the endowment of a "Fanny Hopkin Morris" Bed (unless already given in his lifetime).

University of London Medical Graduates Society

An extra-metropolitan dinner was held on Oct. 13th at the Grand Hotel, Brighton, with Lady Barrett, M.S., the president, in the chair. She pointed out that the society was developing that corporate spirit among the graduates of the medical faculty which the new University building, when erected, should do so much to promote. Mr. McAdam Eccles announced that the membership of the society had now reached 500.

Medical Sickness, Annuity, and Life Assurance Society

Following the quinquennial valuation on June 30th the directors of this society have recommended the following bonuses, subject to confirmation by the annual general meeting on Nov. 16th. Sickness Fund: reversionary bonus, per £1 1*s.* insured, of 12*s.* on all with-profit policies providing for immediate benefit, and ceasing at ages 65 or 60, with proportionately lower bonuses for policies ceasing at other ages, and for those with deferred benefits. Life Assurance Fund: reversionary bonus of £1 3*s.* per cent. on the sum assured in respect of all with-profit whole life and endowment assurances. It is stated that full provision has been made for depreciation of stocks, and that ample reserves set aside for contingencies.

Surgical Instrument Manufacturers' Association

The annual dinner of this association was held at the Holborn Restaurant on Oct. 14th, with Mr. Patrick C. Maw in the chair. After the loyal toasts had been honoured, Mr. Duncan G. Fitzwilliams proposed "The Association," coupled with the name of the chairman. The manufacturing trade and the surgical profession must, he said, stand together. The trade had been badly injured by the tendency of hospitals to buy foreign-made apparatus, but much good had been done by the Government's change of policy. The appeal which he had made by letters to the medical and nursing press had, he hoped, met with a satisfying response; he promised to inquire how many hospitals had adopted his suggestions, and to do his best to interest the council of the Association of Surgeons of Great Britain and Ireland. He could not see, he said, why the people of this country should pay wages to the foreigner when they themselves were out of work. He had tried a complete set of rubber operating furniture, with very satisfactory results, and had determined to install it throughout the hospital, but the manufacturers had made no reply to his request for a quotation made 18 months ago. He told the Association that if its members would manufacture rubber furniture it would sweep the country and entirely displace metal appliances. Mr. Maw, in reply, blamed public bodies as well as hospitals for buying foreign-made goods, mentioning, as an example, the action of a certain county council in specifying on its tender forms a foreign brand of enamel-ware which could be equalled or surpassed in this country. The industry was, he said, largely an hereditary one; his own firm had been founded by his great-great-grandfather, and his grandfather had trained Mr. A. W. Down, the first chairman of the Association. Mr. E. W. Mayer, in proposing "The Guests," warned users of surgical instruments that if no work could be found for the men, in a few years' time there would be no men available for the work. It took six or seven years to train a good maker of surgical instruments, and at present no fresh apprentices were being engaged. Sir Charles Hipwood, director of the National Union of Manufacturers, in reply, spoke on the significance of Ottawa to the industries of the country, and Mr. F. Gladstone Hines, president of the Pharmaceutical Society, acknowledged the help his society had received from the Association, in company with other affiliated bodies.

if all the useful work is retained by one or two men, and none of the others is given a chance to do the bigger things. If the chairmanship and representation on the insurance committee and other outside bodies were by rota, provision would be made for carrying on the work when the older men drop out. The medical profession would do well to look into this aspect of the matter, and even the Minister might consider it worth while to make regulations calculated to arouse more interest in medical administration amongst insurance practitioners in general.

The Defence Trust

The National Insurance Defence Trust was founded in 1919, its trustees being the members for the time being of the Insurance Acts Committee. The objects of the Trust are :—

1. To assist in defraying the expenses incurred in organising or taking any action to protect the interests of the medical profession in connexion with the present National Health Insurance system or any extension or modification thereof.

2. To include, where necessary, financial support of medical practitioners who require such support owing to action taken by them in accordance with any policy laid down or approved by a conference of representatives of local medical and panel committees, or of such committees as may be formed in place of or in substitution for them or either of them, or to which work now discharged by such committees or either of them may, as the result of new legislation, be transferred.

3. The conference referred to in (2) shall take place entirely and solely in the discretion and judgment of the Insurance Acts Committee of the British Medical Association.

In 1926 the panel conference decided there should be no relaxation of efforts to obtain contributions until £250,000 was reached, that information as to the amount of each area's quota should be furnished to all local medical and panel committees, and that any area subscribing its quota might properly suspend further contribution until all other areas had contributed their proper quota or the total amount aimed at had been reached. The present position is as follows :—

—	Percentage of quota subscribed.	Percentage of committees subscribing.		
		100 per cent. or more.	Less than 25 per cent.	Nothing at all.
England ..	73	55	8	4
Scotland.. ..	63	35	18	5
Wales	46	23	47	5

The points which require discussion are :—

(1) What is to be done when £250,000 is reached? Is £250,000 enough?

(2) Are the young people going into practice now in areas where 100 per cent. has been subscribed to make no contribution to defence in case it were needed?

(3) Are the older men in these same areas to cease contributing because £250,000 has been reached, when they are willing to go on with deductions from their panel cheques?

(4) What is to be done with areas which have subscribed nothing in the event of help being needed for defence purposes?

(5) What is the proper use of interest from the investment of these funds? Should it be added to capital or should it be used for purposes which are consistent with the objects of the Trust?

It has been suggested that part of this interest might be used (1) to pay for lectures to final-year students on insurance practice; (2) to help aged and infirm insurance practitioners in their retirement. The interest is already used to defray the expenses of the Insurance Acts Committee, including the rail-fares of its members in attending meetings, as well as the fares of all members of the panel conference who claim them, all of which comes quite definitively within the first object of the Trust. The retirement from the Service of infirm and aged practitioners who have become a danger and a source of adverse comment is also definitely action taken to protect the interests of the medical profession. The same argument might be applied to giving lectures on national health subjects to young men about to qualify; such knowledge would save a doctor many an anxious moment before a medical service sub-committee.

Vacancies

For further information refer to the advertisement columns

Barnsley, Beckett Hospital and Dispensary.—Res. Surg. O. Also H.P. £300 and £200 respectively.

Birmingham and Midland Ear and Throat Hospital.—Asst. Surg. O. £200.

Birmingham, Dudley-road Hospital.—Jun. Asst. M.O.'s. All at rate of £200.

Blackburn County Borough.—Asst. Dentist. £450.

Blackpool County Borough.—Asst. School M.O. £550.

Bradford Royal Infirmary.—H.P. and H.S. Each at rate of £135.

Cancer Hospital, Fulham-road, S.W.—Hon. Neurologist, Hon. Dermatologist, Hon. Gynæcologist. Hon. Ophthalmic Surgeon.

PARLIAMENT

NOTES ON CURRENT TOPICS

Reassembly of Parliament

BOTH Houses of Parliament reässembled on Tuesday, Oct. 18th, after the summer recess.

The business before the House of Lords was purely formal, and the House of Commons devoted the day to the discussion in committee of Ways and Means of the resolutions in connexion with the Bills which are necessary for carrying into effect the agreements reached at the Imperial Economic Conference at Ottawa.

Major ELLIOT (formerly Financial Secretary to the Treasury and now Minister of Agriculture) and Dr. MORRIS-JONES (who has been appointed an Assistant Government Whip) were among the Ministers who took their seats on the Treasury Bench.

Medical Diary

SOCIETIES

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MONDAY, Oct. 24th.—8 P.M., ODONTOLOGY. Mr. A. E. Rowlett: The Gnathodynamometer and its Uses in Dentistry. Mr. J. Draper Cambrook: A Sequestrum of the Palate.

WEDNESDAY.—5 P.M., COMPARATIVE MEDICINE. Mr. W. Horner Andrews: Presidential address. Prof. Edward Hindle (National Institute for Medical Research): The Ætiology of Feline Distemper. Demonstrations: Prof. Edward Hindle: Isospora Bigemina, a Coccidial Parasite of Dogs. Mr. S. J. Edwards: Crystal Violet-æsculum-iron-blood-agar—a Differential Plating Medium for Mastitis Streptococci.

THURSDAY.—8.30 P.M., UROLOGY. Dr. David Band: Chronic Pyelocystitis with Particular Reference to the Ketogenic Diet Treatment. Other speakers: Dr. D. Melville Dunlop and Mr. I. Lawson Dick.

FRIDAY.—5 P.M., DISEASE IN CHILDREN. (Cases at 4.30 P.M.)

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY, Oct. 24th.—8.30 P.M., Discussion on Fractures of the Lower Jaw to be introduced by Mr. W. Warwick James and Sir Harold Gillies.

FRIDAY.—5 P.M., Sir Arthur Keith: Demonstration postponed.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, Oct. 24th, to SATURDAY, Oct. 29th.—MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W. Series of Lectures on Renal Disease. Tues. at 4 P.M. by Mr. John Everidge: Surgical Aspects of Hæmaturia. (Free to Members.)—MILLER GENERAL HOSPITAL, Greenwich, S.E. Second week of the Course in General Medicine and Surgery. All day, demonstrations, operations, and lectures. Specially suitable for general practitioners.—ST. JOHN'S HOSPITAL, Leicester-square, W.C. Clinical instruction daily at 2 P.M. and 6 P.M. Lectures on Tues. and Thurs. at 5 P.M.—CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn-road, W.C. All day course in Diseases of the Ear, Nose, and Throat.—LONDON LIGHT CLINIC, Ranelagh-road, S.W. Lecture demonstration on Physical Medicine, Mon. and Wed., 8 P.M. to 9 P.M.—HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C. Diseases of Children. Mornings only.—CITY OF LONDON MATERNITY HOSPITAL, City-road, E.C. Week-end Maternity Course. Sat. and Sun. All day.—10, BEDFORD-SQUARE, W.C. Dr. A. Knyvett Gordon will give a demonstration on Clinical Pathology (Epidiascope and Laboratory Demonstrations) on Wed., at 8.30 P.M. (Specially suitable for M.R.C.P. Candidates).—These Courses are open only to Members of the Fellowship.

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE, Hammersmith-road, W.

MONDAY, Oct. 24th.—10 A.M. to 12 noon, Skin Department, Surgical Wards. 2 to 4 P.M., Medical, Surgical, Eye, and Gynæcological Out-patients, Surgical Wards. 4.15 P.M., Lecture, Mr. Sangster Simmonds (Surgical).

TUESDAY.—10 A.M. to 12 noon, Medical Demonstration, Surgical Demonstration. 2 to 4 P.M., Medical, Surgical, and Throat Out-patients. 4.15 P.M., Lecture, Mr. Hamblen Thomas: Bronchoscopy and Œsophagoscopy.

WEDNESDAY.—10 A.M., Medical Wards, Childrens' Out-patients. 2 to 4 P.M., Medical, Surgical, and Eye Out-patients. 4.45 P.M., Venereal Diseases Demonstration.

THURSDAY.—10 A.M. to 12 noon, Neurological Department, Fracture Demonstration. 2 to 4 P.M., Medical, Surgical, Eye, and Genito-Urinary Out-patients.

FRIDAY.—10 A.M., Medical Wards, Skin Department. 2 to 4 P.M., Medical, Surgical, and Throat Out-patients.

SATURDAY.—10 A.M., Medical Wards, Childrens' Out-patients, Surgical Wards.

The lectures at 4.15 P.M. are open to all medical practitioners without fee.

HAMPSTEAD GENERAL AND NORTH-WEST LONDON HOSPITAL POST-GRADUATE SCHOOL.

WEDNESDAY, Oct. 26th.—3 P.M., Sir Ernest Graham-Little, M.P.: Voluntary Hospitals and their Future.

HOSPITAL FOR EPILEPSY AND PARALYSIS, Maida Vale, W.

THURSDAY, Oct. 27th.—3 P.M., Dr. Blake Pritchard: Peripheral Neuritis (demonstration).

ST. PETER'S HOSPITAL FOR STONE, POST-GRADUATE COURSE, Henrietta-street, Covent Garden, W.C.

MONDAY, Oct. 24th.—10 A.M., Dr. John Roth: X Ray Demonstration. 2 P.M., Mr. Swift Joly: Operations.

TUESDAY.—10 A.M., Mr. F. J. F. Barrington: Treatment of Stricture and its Complications. 2 P.M., Mr. F. J. F. *Barrington: Operations.* 4 P.M., Mr. Alban Andrews: Out-patient Demonstration.

WEDNESDAY.—11 A.M., Dr. Cuthbert Dukes: Pathological Museum Demonstrations. 3.30 P.M., Mr. A. H. Harkness: Non-specific Urethritis. 5 P.M., Mr. A. H. Harkness: Out-patient Demonstration.

THURSDAY.—10 A.M., Mr. Clifford Morson: Rôle of Radium in Genito-Urinary Cancer. 11 A.M., Wards. 2 P.M., Mr. Ogier Ward: Operations.

FRIDAY.—10 A.M., Mr. Ogier Ward: Cystoscopy in the Female. 2 P.M., Mr. Clifford Morson: Operations. 4 P.M., Mr. Alban Andrews: Out-patient Demonstrations.

SATURDAY.—10 A.M., Mr. Swift Joly: Stone in the Upper Urinary Tract. 11 A.M., Wards. 2 P.M., Mr. J. Sandrey: Out-patient *Demonstration.*

NATIONAL HOSPITAL, Queen-square.

MONDAY, Oct. 24th.—2 P.M., Dr. Riddoch: Out-patient Clinic. 3.30 P.M., Dr. Gordon Holmes: Cranial Nerves and Special Senses.

TUESDAY.—2 P.M., Dr. Walshe: Out-patient Clinic. 3.30 P.M., Dr. Gordon Holmes: Cranial Nerves and Special Senses.

WEDNESDAY.—2 P.M., Dr. Martin: Out-patient Clinic. 3.30 P.M., Dr. Collier: Clinical Demonstration.

THURSDAY.—2 P.M., Dr. Kinnier Wilson: Out-patient Clinic. 3.30 P.M., Dr. Gordon Holmes: Cranial Nerves and Special Senses.

FRIDAY.—2 P.M., Dr. Adie: Out-patient Clinic. 3.30 P.M., Dr. Bernard Hart: The Psychoneuroses.

ST. PAUL'S HOSPITAL, Endell-street, W.C.

WEDNESDAY, Oct. 26th.—4.30 P.M., Mr. Claude H. Mills: Interesting Urological Cases. Specimens, &c.

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL, Denmark-hill, S.E.

THURSDAY, Oct. 27th.—9 P.M., Dr. C. Newman: Dysfunction of the Gall-bladder.

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION, St. James' Hospital, Ouseley-road, Balham, S.W.

WEDNESDAY, Oct. 26th.—4 P.M., Dr. H. J. Churchill: Anæsthetics in General Practice.

ROYAL INSTITUTE OF PUBLIC HEALTH, Queen-square, W.C.

WEDNESDAY, Oct. 26th.—4 P.M., Dr. Chalmers Watson: Food and Problems of Nutrition in Regard to Preventive Medicine.

THURSDAY.—4 P.M., Prof. R. J. A. Berry: Opens discussion on Mental Defectiveness: Medical and Social Considerations.

NATIONAL COUNCIL FOR MENTAL HYGIENE.

WEDNESDAY, Oct. 26th.—5.30 P.M. (at 11, Chandos-street, W.), Dr. W. Brown: Rationalisation.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 49, Leicester-square, W.C.

TUESDAY, Oct. 25th.—5 P.M., Dr. A. M. H. Gray: Xanthoma. Herpes.

THURSDAY.—5 P.M., Dr. K. Sibley: Principles of Treatment. Local.

MANCHESTER HOSPITAL FOR CONSUMPTION AND DISEASES OF THE THROAT AND CHEST, Hardman-street, Deansgate.

WEDNESDAY, Oct. 26th.—4.30 P.M., Mr. E. S. Burt Hamilton: Nasal Suppuration.

MANCHESTER ROYAL INFIRMARY.

TUESDAY, Oct. 25th.—4.15 P.M., Mr. D. L. Sewell: Cancer of the Larynx and its Treatment by Radium.

FRIDAY.—4.15 P.M., Dr. T. H. Oliver: Demonstration of Medical Cases.

ANCOATS HOSPITAL, Manchester.

THURSDAY, Oct. 27th.—4.15 P.M., Mr. P. G. McEvedy: Carcinoma Colon.

Mental After-Care Association

A meeting of this association will be held at the Springfield Mental Hospital, Upper Tooting, at 3 P.M. on Tuesday, October 25th. Lord Wakefield will preside, and the speakers will include the Dean of Westminster, Miss Ruth Darwin, Mr. E. J. Sainsbury, and Mr. C. L. de Salis. The hospital will be open for inspection. The address of the association is Church House, Westminster.

Glasgow Post-Graduate Medical Association

A series of lectures will be given at 3.30 P.M. on Tuesdays from Nov. 15th in the hall of the Royal Faculty of Physicians and Surgeons, dealing with some practical problems in the light of recent research. They are open to medical practitioners without fee. At 4.15 P.M. on Wednesdays from Nov. 2nd there will be clinical demonstrations. Special courses in ophthalmology will be held at the Glasgow Eye Infirmary; there will be demonstrations at the Ear, Nose and Throat Hospital, and the Radium Institute will give a course on Radium Therapy. Facilities for the study of clinical obstetrics and antenatal work are offered at the Royal Maternity and Women's Hospital. The secretary of the association is Dr. James Carslaw, 9, Woodside-terrace, Glasgow, C. 3.

Ladies' Medical Golfing Society

At the Autumn meeting, held at Selsdon Park on Oct. 14th, the following competitors were successful:—Cecil Leitch Challenge Cup (best net return): Mrs. Collis Browne (5) and Mrs. R. Y. Paton (14), 79, Mrs. Collis Browne winning on the last 9 holes. Scratch, First Division: Mrs. Collis Browne, 84. Second Division: Mrs. Hobson, 108. Handicap Prizes, First Division: Mrs. R. Y. Paton, 93 – 14 = 79; Miss Griffiths, 97 – 17 = 80; Dr. S. Horner, 90 – 6 = 84. Second Division: Mrs. Palmer, 111 – 19 = 92; Lady Lett, 113 – 19 = 94; Mrs. Mortimer Woolf, 133 – 29 = 104. Best Ball Competition: Mrs. Collis Browne and Mrs. Lewis Smith, 77½. Captain's Prize: Mrs. Collis Browne. Greensomes *v.* Bogey: First, Mrs. Oldershaw (14) and Dr. Horner, 2 down; Second, Mrs. Palmer (19) and Miss Griffiths (17), 2 down.

Fellowship of Medicine and Post-Graduate Medical Association

Arrangements for the coming week will be found in our Medical Diary. A week-end all-day course will take place at the City of London Maternity Hospital on Oct. 29th and 30th. The first of a series of three demonstrations on clinical pathology, designed for M.R.C.P. candidates, will be given by Dr. A. Knyvett Gordon, at 10, Bedford-square, W.C., on Wednesday, Oct. 26th, at 8.30 P.M. From Oct. 31st to Nov. 19th an afternoon course in ophthalmology will be given at the Royal Westminster Ophthalmic Hospital, and there will be a course in neurology at the West End Hospital for Nervous Diseases daily at 5 P.M. from Oct. 21st to Nov. 26th. Other courses taking place during November are as follows: medicine, surgery, and gynæcology at the Royal Waterloo Hospital, Nov. 7th to 26th (afternoons and some mornings); diseases of the chest at the Victoria Park Chest Hospital, Nov. 14th to 26th (all day); venereal diseases at the London Lock Hospital, Nov. 14th to Dec. 10th (afternoons and evenings). Further details of these courses may be had from the secretary of the Fellowship at 1, Wimpole-street, London, W. 1.

Birmingham University Dental School

The annual distribution of prizes took place at the Birmingham Dental Hospital on Oct. 13th. Sir Thomas Horder, who presented the prizes, was welcomed by Mr. W. Malcolm Knott, chairman of the surgical committee. In reviewing the work of the year, Mr. Knott said that good progress had been made, and that both the school and the hospital had benefited from their interdependence. He referred particularly to the facilities offered to the students in the study of the use of anæsthetics. The Dental Board of the United Kingdom had made a grant of £500 conditionally on the school doing the same. The money had been spent on new equipment. In conclusion Mr. Knott said that the registration of dentists was going to prove of great benefit to the public, and commented on the many opportunities now offered to the well-trained young man or woman in this profession. Sir Thomas Horder, speaking to the students on the career they had chosen, said that he held heterodox views about careers. He believed that it did not matter what one chose to do so long as one tackled it in the right spirit. He affirmed that the three necessary qualities were courtesy, courage, and concentration. The job his hearers had chosen was one which would bring them into contact with their fellow men and he wished them every success in their calling.

New Operating Theatres at Birkenhead

Lord Leverhulme recently opened new twin theatres at Birkenhead General Hospital. The cost has been £9000; each theatre is 25 ft. long and 18 ft. wide. They communicate, and one of them opens into a corridor giving direct access to the X ray department. The walls are finished in a soft green matt enamel to prevent overstrain and glare; the ventilation is by concealed ducts and electric exhaust fans; shadowless lamps travelling on rails are suspended over each operating table.

International Society of Medical Hydrology

The annual meeting of members and the council meeting of this Society were held in Paris on sunday, Oct. 16th, at the conclusion of the International Congress on Rheumatism which had been attended by a large number of its members from many countries, including South Africa and the United States. In the absence of the retiring president, Prof. W. S. Thayer (Baltimore), the chair was taken by the president vice-gerent, Dr. J. van Breemen (Amsterdam), until the election of the new president, Dr. Paul Ferreyrolles (La Bourboule and Paris). On the retirement of Dr. C. W. Buckley (Buxton) as treasurer, Dr. Lionel Calthrop (Radlett, late of Harrogate) was elected in his place. It was decided to hold the next business meeting of the society at Toulouse in October, 1933, at the time of the Congrès International d'Hydrologie, and the next scientific meeting at Zürich in January, 1934.

London Hospital Dinner

Presiding over a large gathering at the Trocadero on Oct. 13th, Sir Henry Newland echoed Dr. Johnson's: "Sir, when a man is tired of London he is tired of life." Returning to England after 13 years' absence he had set his heart on attending this dinner and felt that his position as chairman made the pomp of emperors look ridiculous. After congratulating the house committee on avoiding Lord Randolph Churchill's mistake of forgetting Goschen, he passed on to congratulate both those whose distinction at the London had led to their appointment at other schools and those whose distinction elsewhere had led to their appointment to the London. In a long series of distinctions of the year he mentioned Sir Ernest Morris's knighthood, Lord Dawson's success as president of the British Medical Association, Mr. G. Northcroft's election as president of the British Dental Association, and Prof. William Bulloch's appointment as chairman of the Lister Institute. The entry to the medical college, he said, was very good, and the entry from Cambridge a record since the war. As to sport, the London had done well in inter-hospital shooting and sailing. (Laughter.) But in Sir Henry's opinion the golden age of the hospital was 1895–1905 when L. A. Smith and Hugh Rigby were R.R.O.'s (and evidently made the most of it). Returning to the present, he said that there would soon be plenty of room for men with little capital to start practice in the country districts of Australia, where life was no longer lonely. In London he had been interested in noting the centrifugal migration of the population and thought that the great hospitals should buy sites cheaply while they could and should move with the tide of humanity outwards to sunlight and fresh air.—Mr. Russell Howard said he had refused to speak (1) because he was a tongue-tied and almost inarticulate Englishman and (2) because he had a life-long grudge against the chairman. In the days when there was but one surgical registrar (a ewe lamb, not a flock) they were rivals for the post and Newland got it. But the real trouble was that Newland then withdrew to Australia and left him to his registrarship and thereafter to a bare existence teaching the obvious to the incompetent. But for this he might have been a successful practitioner with a lock-up surgery. Mr. Howard, nevertheless, admired Sir Henry profoundly because he was one of the few Australians who had returned to their country; because he had never called himself Simpson-Newland; and for other reasons. The fact that he was second president of the Royal Australasian College of Surgeons spoke for itself.

Mr. Hugh Lett then made an impressive appeal for funds for the new students' hostel. This was urgently needed, he said, because even the sons of old Londoners were going elsewhere for lack of the corporate life which was of such immense importance in training for medical practice. The original estimate of £50,000 had been reduced to £23,000; £6000 had been collected; the house committee had voted a further £3000; and now that the whole of the Philpot-street frontage had become available a beginning was to be made with the north wing. He asked in Lord Knutsford's phrase, that everyone should give as much as he could uncomfortably spare; and in this spirit over £250 was contributed within a quarter of an hour by a few of his hearers.

people recommend the remedy, and take the responsibility upon themselves without having any idea that they are preventing their friend or relative from consulting a doctor. Or they advise him to consult a quack, who, for much money, gives him some worthless herb or ointments, and meanwhile the precious time passes away.

The Educational Campaign

Doctors often find themselves in a difficult position when asked to say whether or not a patient is suffering from cancer; we must, however, confess that it is sometimes just as difficult to be the patient. If he consults the doctor when he has an advanced cancer, he is reproached for indifference to his health; and if the doctor does not find anything, his relations and friends accuse him of being afraid and consulting doctors in season and out of season.

The obstacles in the way of an early recognition of cancer are partly due to its insidious development and partly to human faults and virtues, and that is why these obstacles are so difficult to overcome. It is tempting to stop all propaganda, especially as it may cause an exaggerated fear among unbalanced people and turn them into cancerophobes. We hope, however, that educational measures about cancer may help somebody to be properly treated in due time, especially when these measures are concentrated on the points that experience shows to be the public's weak side. The main thing is, by constant repetitions, to hammer the following points into the public mind:—

(1) Cancer is no incurable disease; it can be fully eradicated when treated early.

(2) For the time being we know only two methods for the radical treatment of cancer: operation and X rays or radium, separately or combined.

(3) Cancer often begins without pain or with very slight pain.

(4) Cancer at the onset causes no other symptoms than those following any insignificant disease of the same organ.

(5) Indigestion is not a disease, but a painful symptom produced by many possible diseases, both within and outside the abdominal cavity—e.g., ulcer of the stomach, gall-stones, appendicitis, intestinal diseases, and diseases of the internal sex organs; it may also be due to cancer of the stomach, intestines, liver, and kidneys.

(6) Cancer is so common after the age of 40–50 that everyone must consider the possibility of getting it, even if his previous health has been of the best.

(7) The worst thing that can be done by one who imagines himself to be suffering from early cancer is to give up hope at once and hide the disease, instead of consulting the doctor in time.

THE HOSPITALS OF AMSTERDAM

In Amsterdam, as in England, the function of hospitals during recent years has undergone a fundamental change; at one time the refuge of those who could afford no other care, they have gradually become centres of first-class treatment and equipment, and have begun to draw patients from all classes of society. Dr. J. L. C. Wortman, in an account of the Amsterdam hospitals,[1] writes with regret of the delays which have attended the development of the municipal hospital system in Holland. Repeated schemes have been agreed upon, only to be discarded. "No more striking example can exist," Dr. Wortman remarks sadly, "of the unreliability of the decisions of municipal councils." Nevertheless, two of the oldest hospitals in Amsterdam are municipal. One of these, the St. Elisabeth Gasthuis, was founded in the fourteenth century, and was later combined with the St. Peter Gasthuis, built by a fisherman's guild, a hospital which, besides being provided with a pest-house, gave temporary lodging to vagabonds and homeless persons. A discouraging offer of hospitality was carved over the entrance:

> "Three nights, not longer,
> I lodge who need it;
> The fourth I keep out
> The beggars and the knaves."

Later, in the sixteenth century, the patients of the St. Peter's Gasthuis were removed, bag and baggage, to a block of convent buildings which had been appropriated by the city government, and which were to provide the site of the present hospital. In the seventeenth century a new pest-house was built outside the city, and the plague cases no longer shared the same buildings as other patients; the two hospitals became known as the Inner and the Outer Hospitals. The Outer Hospital was replaced by a new building, the Wilhelmina Hospital, in 1885, and it is significant that even at that time a section was included where private patients could be treated, who would provide a source of income to the hospital. The Inner Hospital has never been completely rebuilt, but has suffered piecemeal reconstructions and additions. The Wilhelmina Hospital is now to become a complete university institution, and is undergoing reconstruction for that purpose. Dr. Wortman remarks that in the pavilion for infectious cases at the Wilhelmina Hospital, "during visiting hours, thick ropes are stretched from each side of the door across the ward, so that visitors can walk along the beds looking at the patients without coming into contact with them." This arrangement is more sociable than observation through a glazed partition, more usual elsewhere, and it would be interesting to learn if it has proved free from the risk of infection in either direction. A third municipal hospital is the Tesselschade, which began as a temporary institution, but which soon became a much-needed permanency.

In addition to the municipal hospitals, Dr. Wortman describes the private hospitals of the city. The Holy Virgin Hospital, built in 1898, was at that time equal to the best institution of its kind in Europe, and has kept pace with modern developments. Many other general and special institutions are described in a work which appears to give a complete account of hospital facilities in Amsterdam.

CONSTIPATION WITH INCONTINENCE

In 1923 I. Thorling described a condition which he called constipation incontinence. His three patients, boys between the ages of 6 and 7, suffered from incontinence of the bowels which he attributed to constipation. His suggestion that such incontinence might prove not to be uncommon, is confirmed by Dr. C. E. Bloch,[1] of Copenhagen, who states that though the text-books do not yet mention this disorder, he has lately observed as many as seven cases. All his patients were children over the age of 7; and they were otherwise perfectly normal and well developed. All had previously had normal control over the bowels. The incontinence had developed gradually, at first only during the day. Later it became more frequent and occurred also at night. It would occur when the children were greatly excited over their exercises and games, and they were unaware of what had happened till the stools were actually in the clothing. One of the most distressing cases was that of a boy between 7 and 8, a pupil in the ballet school of the Royal Theatre, Copenhagen. While he was on the stage, brown spots would appear on the back of his white tights—a display which led to his dismissal. On admission to hospital he was found to be miserable and ashamed. The sphincter of the anus was somewhat relaxed, and the rectum was filled with fæces even immediately after the bowels had acted. In only one of the seven cases was the involuntary action of the bowels accompanied by enuresis; and

NOTES, COMMENTS, AND ABSTRACTS

DELAY IN SEEKING RADICAL TREATMENT FOR CANCER

WORDS TO THE LAITY AND THE LEARNED

BY PROF. P. BULL, M.S. OSLO

ALL doctors know that patients suffering from cancer may be cured if only they are given radical treatment at the beginning. Some of the public also know this; and yet patients suffering from cancer are seldom put under treatment in an early stage of their illness. This is especially true of cancer of the internal organs, which forms the great bulk of all cancer.

What is the cause of this regrettable state of affairs? It may easily be thought that the fault lies with the doctors who have not the ability to diagnose the disease in an early phase. Apart from this, however, the following circumstances mainly prevent an early recognition of cancer: (1) wrong popular ideas of cancer; (2) its insidious progress in the early stages; and (3) the differing attitude of different people towards cancer and the possibility of it.

Many people, perhaps most, are fully convinced that cancer is an incurable disease, which it is no use to fight against. Most people believe that cancer is a painful disease accompanied by an appearance of illness, by ulceration, and by foul discharge. This picture undoubtedly fits many forms of cancer in an advanced phase, but does not at all conform to that of cancer at its outset, when it is very often not accompanied by pain, or any pain there may be is so slight that the patient does not believe it to be of any importance. This idea of pain is so deeply rooted in the public mind that patients often say, "But I cannot be suffering from cancer with no worse pain than this." Nor are any other alarming and characteristic symptoms found at the onset of the disease. It is not accompanied by any inconveniences other than those which may be found in any common and benign disorder. It is not unusual to find a patient suffering from cancer weighing about 90–100 kg. and looking blooming.

Since cancer in the early stages steals upon the patient, it is clear that different people will react to such vague and indefinite symptoms according to their character, according to their prejudices about cancer—in fact, according to their whole view of life. Let us take a few examples.

Various People

Those afraid of doctors.—Those who do not dare to consult a doctor lest their suspicion of cancer be confirmed prefer to go on in uncertainty. The fear of an operation contributes to their attitude, for most people know that operation will probably be proposed if they have cancer. Fear prevents these patients from thinking quietly and soberly; they try to conceal their disease until it is clear both to themselves and to those around them that it has become a question of health and perhaps of life. When they do see a doctor the time for cure has passed, and yet they demand that the doctor shall cure them, and are by now willing to submit to any operation, even if the prospect of a good result is minimal. So in the end it proves not to have been the fear of doctor or operation which held them back, but the fear of death, and it is this fear that makes them an easy prey to the man with the scythe.

If such a patient had at once sought skilful help the doctor might have said: "You are not suffering from cancer." Thereby he would have got rid of an unnecessary anxiety—quite a pleasant result of a consultation. Or the doctor might have said: "This looks doubtful, I cannot say anything without further examinations, which will last a few days." After some anxious days the doctor might have reached the same conclusion: "You are not suffering from cancer." Or he might have said: "I am sorry, but this looks serious, and an operation or treatment by rays is necessary"; but he would have added: "You will probably be quite all right, because you have consulted me in an early phase of your disease."

Those afraid of cancer, the cancerophobes, are quite different. They do not think and do not talk of anything but cancer; at the slightest pain or inconvenience they consult the doctor, and insist that they have a lump in the breast, a sore tongue, and so on, though the doctor cannot find anything wrong. Discontented at his failure they go from one practitioner to another—unhappy creatures, whom we may pity, but they are not suffering from cancer.

Quiet and considerate patients do not at once consult the doctor if they feel some vague pains somewhere, as long as they are fairly fit for work. They think that they must work and earn their livelihood; or they have perhaps just started a new enterprise, where their daily presence is needed; or they have started some special work which must be completed. Perhaps they vaguely feel that everything is not as it ought to be, but resolve when they have finished this or that they will consult the doctor. This commendable energy may often prevent an early acknowledgment of disease.

The optimists know, perhaps, that after the age of 40 or 50 many people die from cancer, but for themselves they may be compared to the soldiers in war: they see their comrades fall, but they always imagine that they themselves will go free. They support this idea by some very plausible arguments: they have all their lives been perfectly sound and healthy and they belong to a family with many examples of longevity. They have always lived a sober life, observing all the rules of health. They seem to think it a terrible injustice that they should get cancer. But the optimists must remember that cancer is merciless and makes no distinction between just and unjust, between rich and poor, between excellent people and rogues, or between sound people and infirm ones; and cancer always comes as a surprise and an inconvenience.

Those feeling impelled to explanations.—Some people suffer from a woeful need to hide their ignorance by explanations of all the phenomena of life, and, worst of all, this satisfies them better than anything else. When these people are ill they always have an explanation ready. Pains are "only rheumatism"; pain or discomfort caused by food is "only indigestion." They are fully convinced that they will get all right again, "they know themselves well enough," and so on. If they feel a lump somewhere, it is only the consequence of a blow that hit them just there a fortnight or so ago. These people, with their self-made explanations, are difficult to treat, and if they get cancer they very often do not consult the doctor until they begin to lose their ability to work and their spirit. When the doctor tells them the real cause of their rheumatism, indigestion, or lump, they are much surprised and raise objections.

The fanatics, through religious conviction or mere stupidity, maintain that diseases do not exist, or in any case that it is unnatural to be treated by a doctor. If these people get cancer they always come too late; they will not consult the despised doctor until "spiritualism" and all sorts of "natural methods" have robbed them of the favourable moment.

Unfortunate advice from relations and friends is another obstacle to early acknowledgment of cancer. When the patient complains of discomfort after food, irregular bowels, irregular bleeding, or indefinite pains, there is always someone who knows an excellent remedy for just that disease. These benevolent

ADDRESSES AND ORIGINAL ARTICLES

PSYCHOLOGICAL FACTORS IN THE PREVENTION AND TREATMENT OF ALCOHOL AND DRUG ADDICTION*

By J. R. Rees, M.D. Camb., D.P.H.

DEPUTY DIRECTOR OF THE INSTITUTE OF MEDICAL PSYCHOLOGY, LONDON

In the far past, before medicine set out to become an exact science, there was, it would seem. considerable insight into the emotional factors in the causation of bodily and mental sickness. With the increasing emphasis on objective facts, much of this was lost. In the last 30 years, and more particularly since the war, the pendulum has been moving very obviously in the opposite direction, to a wider and a saner outlook. The study of the whole individual—human medicine—which necessarily includes the assessment of mental and emotional states as well as structural and physical disorder, is stimulating the imagination and claiming the attention of the medical profession, both general practitioners and specialists of every kind, since it opens doors which had hitherto remained closed. Medical psychology, the least taught, though by no means the least important branch of our work, has therapeutic possibilities which we have only begun to explore.

There is, of course, no difference of opinion about the end-results of the addictions, the toxic effects of alcohol and other drugs with which we are all familiar. Those in themselves present many problems, but we are not discussing them here. One should, I believe, keep an open mind on the question of the degree in which chemical action helps in the formation of the drug habit—certainly there is a vicious circle set up. The effect of increasing tolerance upon the individual may also be important, but I cannot help feeling that beyond doubt the essential causative factor in these conditions is a habit of mind. an attitude towards life. Alcoholism and drug addiction are, in almost every case, the symptoms of a psychological maladjustment. These abnormalities of outlook and conduct are as much symptoms, as a pain in the præcordium may be the symptom of a damaged and badly compensated heart. To treat the symptom may be very wise at times, but it is essential that we should try to acquire a causal therapy.

Very largely, therefore, the problems of prevention seem to me to fall within the sphere of mental hygiene and those of treatment are to be solved by wise psychiatry, though by saying this I do not intend to imply that specialist knowledge is always needed.

The Approach to Addiction

To my mind there is no very obvious and fundamental difference between the psychology of the alcoholic and that of the drug addict. Differences of opportunity will sometimes explain the particular directions in which people indulge themselves. It has occurred to me that often those who take drugs other than alcohol are of a rather less intelligent type than their social equals who over-drink. The mental stimulation of drugs is to them an additional motive for their action.

The most usual reply that I have received when I have asked addicts why they take their particular drug is: "Because I am fed up," though all of them have to add that they now cannot do without it. It is probable that the same answer would be given by a majority of occasional drinkers and by all secret drinkers, though they would naturally couple with that answer the fact that they liked alcohol, because it relieved them of their sense of oppression at having to stand up to the circumstances of life.

Whatever psychological or emotional factors may be at work, it is certain that there are many physical conditions which lead up to "breakdowns" or addiction. Toxæmia, whether from fatigue or from septic foci, a lowered blood pressure, and endocrine failures may be mentioned as some of the many conditions which must be investigated and treated if the individual is to be at his maximum capacity to deal with his problems and habits. Mental defect, epilepsy, and manic-depressive psychoses must also be mentioned for their share in producing addictions in certain cases.

The most important approach to these conditions is, however, without doubt, through their psychological aspects. Unwillingness or inability to meet the strains of life, which finds relief in alcohol, may be the result of an almost infinite number of causes. It is doubtful whether there ever can be a state of addiction without antecedent emotional disturbances. In the main, the cause of addiction is endopsychic—in the personality of the sufferer—though environmental factors precipitate the trouble in the majority of instances. One wonders what were the personal problems of those many hundreds of doctors who, we are told, wrote such glowing testimonials to that well-known product of the Irish Free State! It must at least have appeared to be "good for" them. Their enthusiasm cannot have been merely due to gratitude for a sample.

Maladjustment and Regression

The square peg in the round hole is perhaps the best way of illustrating the maladjustments that occur in the life of every individual. Few of us are always in a position to adapt perfectly to our circumstances in life. Obviously in a great many cases the capacity to adapt is almost entirely lacking. The ordinary practice in psychological medicine in dealing with children is to attempt the alteration of environment, so as to minimise the problems and modify the difficulties for the child. With adults this is not as a rule possible, nor is it indeed very desirable, since it is hard to produce a permanent improvement in this way. The child, as it grows up, should learn to remove some of its own square corners, and the adult neurotic, provided he has reasonable intelligence, has always to do this if he is to be free of his difficulties. Put in this way, it is clear that a good many adults fly to alcohol because it saves them from feeling that they do not fit into life.

Psychological regression is the most important fact in the pathology of most psychoneuroses and in all cases of addiction. Retreat from the difficulties of life is permissible and advisable up to a certain point. Fairy-stories present life to children in a form which they can understand, and make-believe softens a great deal of the undue hardness of reality. We permit ourselves many forms of retreat in adult life; food, bed, holidays, books, and aspirin—all of these have their reasonable place in our scheme of life. The relief of pain or of tension is of real value for our efficiency and happiness. It is a perfectly admissible argument that alcohol has a place also in the life of the ordinary man. The difficult point to decide is just in this respect constipation incontinence seems to differ from the ordinary distraction incontinence of small children, and from the incontinence of mentally defective children. All seven patients had been subjected to severe discipline, most of them had also been under medical treatment, and a few had been treated in hospital without a correct diagnosis being made or a cure effected. The severe discipline these children had undergone had made them quiet, timid, and ashamed. It is probable that bad habits constituted the chief cause of this complaint, the children getting accustomed to suppress the call to defæcate when at play or work. The treatment consisted of an ordinary diet supplemented by 15 to 30 c.cm. of liquid paraffin taken daily. Every day, at a certain hour, the children were made to sit on the chamber, with their feet on the floor, so that they could apply the maximum of abdominal pressure. When as much fæces as possible had thus been evacuated, a glycerin enema was given. Early in the treatment it yielded large quantities of fæces; later the glycerin enema, usually undiluted, was given only every second or third day. In every case complete success followed this treatment.

NEW PREPARATIONS

WE have received from Messrs. Burroughs Wellcome and Co., Snow Hill Buildings, London, E.C., three preparations: (1) Iodised "Moogrol"; (2) Stipolac; (3) Concentrated liquid liver extract.

(1) IODISED "MOOGROL."—This preparation for the treatment of leprosy is a mixture of esters of the acids of the chaulmoogric series combined with 0·5 per cent. of iodine. The addition of the iodine is designed to reduce—and succeeds in its object—the irritating properties of the ethyl esters. Preliminary clinical experience confirms that Iodised "Moogrol" is less irritating than plain "Moogrol." At a conference on leprosy, held at Manila in January, 1931, the use of iodised esters, particularly by the intradermal method, was strongly recommended. The method has been employed by the Philippine workers for some years, and the advantages claimed are that it produces a more rapid resolution of the superficial lesions and that it is relatively free from general and local reactions. Iodised "Moogrol" is issued in bottles of 25 c.cm., 100 c.cm., and 1 litre.

(2) STIPOLAC.—This is a preparation for use in the radiographic examination of the gall-bladder, to which the name "Stipolac" Brand Sodium Tetraiodophenolphthalein is given. The product is supplied in two tubes containing (1) "Stipolac" Brand Sodium Tetraiodophenolphthalein, and (2) "Stipolac" Brand Acid Mixture respectively. The contents of the two tubes are to be mixed before administration.

(3) CONCENTRATED LIQUID LIVER EXTRACT is intended to supplement, or replace the whole of, the amount of fresh liver in a daily diet. It is a palatable product, can be taken over long periods, and is issued in bottles of 4 and 16 fluid ounces, 1 fluid ounce containing the equivalent of 8 ounces of liver.

GLUCATOR.—This apparatus for the quantitative estimate of sugar in the urine is supplied by Messrs. H. R. Napp, Ltd., 3 and 4, Clement's-inn, Kingsway, W.C. It is packed in a neat and handy manner and is designed to enable the practitioner to make an accurate quantitative estimation of sugar in the urine in two or three minutes. Very clear instructions for its use are included in the case, as well as colour charts which show the successive tints of the reagent on the addition drop by drop of the urine of a diabetic patient. We can see that the apparatus should be of considerable practical service.

HALIBUT LIVER OIL, COLLOSOL BRAND.—We have received from the Crookes Laboratories (Gorst-road, Park Royal, London, N.W.) this preparation described as a natural concentrate giving 50 times the vitamin A value of the finest cod-liver oil. Halibut oil has been shown to have a high vitamin A content, but its extraction is attended with laboratory difficulties over which the firm state that they have triumphed. It should be added that the preparation is stated to contain a definite quantity—namely, 2000 international units per gramme—of vitamin D.

THE HUMOUR OF MEDICINE

COLLECTIONS of stories illustrating the humorous side of medical practice have appeared before, while in all old jest-books the medical anecdote figures prominently, and is regularly reproduced in modern journalism, touched up to meet topical situations. We have received from *Rinascenza Medica* an Italian compilation in which we find many new and some good jokes, appearing side by side with some old and many poor jokes. The illustrations are also mixed in quality, those reproduced from Italian newspapers being particularly woolly. But for the sake of the better part of the collection "Il Medico si diverte" is worth perusing, and it can be got at 3, Cesario Console, Naples, in return for L.40.

AS OTHERS SEE US

THE *Siècle Médical* for Oct. 15th, under the heading "English hospitals in the search for resources are to institute a lottery in a continental country to tap foreign money, lotteries being forbidden in Great Britain," pictures the situation in the following words: "English hospitals are in a terrible crisis; for private subscriptions, in spite of considerable publicity in the press, are diminishing, and the boards of managements are much disturbed. It is known that, generally speaking, English hospitals are supported solely by private charity, the only State or municipal organisations being some defective enough consultation services and a system of assistance by the 'workhouses,' which partake more of the prison than of the hospital. Nothing in England resembles our powerful and benevolent *Assistance publique.*"

IRISH NATIONAL HEALTH INSURANCE COMMISSION. In p. 864 of our last issue, in referring to the National Health Insurance Commissioners of the Irish Free State, the name of Mrs. Alfred Dickie was inadvertently given as Mr. Alfred Dickie.

Appointments

PARRY, RUPERT, M.B., B.S. Lond., has been appointed Honorary Assistant Ophthalmic Surgeon to the Cardiff Royal Infirmary.

East London Child Guidance Clinic, Bell-lane, E.: P. LIONEL GOITEIN, M.B., B.S. Lond., D.P.M. Lond., Hon. Asst. Psychiatrist. AMY M. THOMS, M.D. St. And., M.R.C.P., Hon. Assistant Psychiatrist.

Births, Marriages, and Deaths

BIRTHS

COTTON.—On Oct. 8th, at Whitecross-road, Hereford, the wife of Dr. O. J. C. Cotton, of a daughter.

MACDONNELL.—On Oct. 15th, at 5, Upper Mount Street Crescent, Dublin (nursing home), to Sheila, wife of J. J. MacDonnell, M.B., of Avoca, Hook, Surbiton—a son.

MARRIAGES

BLAIN—MACLEOD.—On Oct. 15th, at Old Parish Church, Nairn, James Alexander Blain, M.B., Ch.B., to Sheila Louisa, [illegible] O., H.M.I.S., younger daughter of [illegible] and of Mrs. Macleod [illegible]

PEIRCE—THOMPSON.—O[illegible] orge Edward Graves Peirce, M.[illegible] [illegible] hompson, of Wimpole-mews, W.1.

DEATHS

BAILEY.—On Oct. 10th, suddenly, at Rugby-road, Brighton, Henry James Bailey, M.B., C.M., aged 67 years.

BRIDGER.—On Oct. 10th, at Royal-terrace, Southend-on-Sea, Sydney Bridger, M.R.C.S., L.R.C.P., aged 60 years.

JENKINS.—On Oct. 10th, at High Oaks-road, Welwyn Garden City, Herbert Thomas Jenkins, M.R.C.S., L.R.C.P.

PRITCHARD.—On Oct. 14th, at a London hospital, Edward J. Pritchard, M.R.C.S. Eng., L.R.C.P., late of West Side, Wandsworth Common.

SYED.—On Oct. 14th, at King's College Hospital, London, after a very short illness, Hassan Syed, M.R.C.S., L.R.C.P., aged 32.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

ADDRESSES AND ORIGINAL ARTICLES

PSYCHOLOGICAL FACTORS IN THE PREVENTION AND TREATMENT OF ALCOHOL AND DRUG ADDICTION*

By J. R. Rees, M.D. Camb., D.P.H.
DEPUTY DIRECTOR OF THE INSTITUTE OF MEDICAL PSYCHOLOGY, LONDON

In the far past, before medicine set out to become an exact science, there was, it would seem, considerable insight into the emotional factors in the causation of bodily and mental sickness. With the increasing emphasis on objective facts, much of this was lost. In the last 30 years, and more particularly since the war, the pendulum has been moving very obviously in the opposite direction, to a wider and a saner outlook. The study of the whole individual—human medicine—which necessarily includes the assessment of mental and emotional states as well as structural and physical disorder, is stimulating the imagination and claiming the attention of the medical profession, both general practitioners and specialists of every kind, since it opens doors which had hitherto remained closed. Medical psychology, the least taught, though by no means the least important branch of our work, has therapeutic possibilities which we have only begun to explore.

There is, of course, no difference of opinion about the end-results of the addictions, the toxic effects of alcohol and other drugs with which we are all familiar. Those in themselves present many problems, but we are not discussing them here. One should, I believe, keep an open mind on the question of the degree in which chemical action helps in the formation of the drug habit—certainly there is a vicious circle set up. The effect of increasing tolerance upon the individual may also be important, but I cannot help feeling that beyond doubt the essential causative factor in these conditions is a habit of mind, an attitude towards life. Alcoholism and drug addiction are, in almost every case, the symptoms of a psychological maladjustment. These abnormalities of outlook and conduct are as much symptoms, as a pain in the præcordium may be the symptom of a damaged and badly compensated heart. To treat the symptom may be very wise at times, but it is essential that we should try to acquire a causal therapy.

Very largely, therefore, the problems of prevention seem to me to fall within the sphere of mental hygiene and those of treatment are to be solved by wise psychiatry, though by saying this I do not intend to imply that specialist knowledge is always needed.

The Approach to Addiction

To my mind there is no very obvious and fundamental difference between the psychology of the alcoholic and that of the drug addict. Differences of opportunity will sometimes explain the particular directions in which people indulge themselves. It has occurred to me that often those who take drugs other than alcohol are of a rather less intelligent type than their social equals who over-drink. The mental stimulation of drugs is to them an additional motive for their action.

The most usual reply that I have received when I have asked addicts why they take their particular drug is: "Because I am fed up," though all of them have to add that they now cannot do without it. It is probable that the same answer would be given by a majority of occasional drinkers and by all secret drinkers, though they would naturally couple with that answer the fact that they liked alcohol, because it relieved them of their sense of oppression at having to stand up to the circumstances of life.

Whatever psychological or emotional factors may be at work, it is certain that there are many physical conditions which lead up to "breakdowns" or addiction. Toxæmia, whether from fatigue or from septic foci, a lowered blood pressure, and endocrine failures may be mentioned as some of the many conditions which must be investigated and treated if the individual is to be at his maximum capacity to deal with his problems and habits. Mental defect, epilepsy, and manic-depressive psychoses must also be mentioned for their share in producing addictions in certain cases.

The most important approach to these conditions is, however, without doubt, through their psychological aspects. Unwillingness or inability to meet the strains of life, which finds relief in alcohol, may be the result of an almost infinite number of causes. It is doubtful whether there ever can be a state of addiction without antecedent emotional disturbances. In the main, the cause of addiction is endopsychic—in the personality of the sufferer—though environmental factors precipitate the trouble in the majority of instances. One wonders what were the personal problems of those many hundreds of doctors who, we are told, wrote such glowing testimonials to that well-known product of the Irish Free State! It must at least have appeared to be "good for" them. Their enthusiasm cannot have been merely due to gratitude for a sample.

Maladjustment and Regression

The square peg in the round hole is perhaps the best way of illustrating the maladjustments that occur in the life of every individual. Few of us are always in a position to adapt perfectly to our circumstances in life. Obviously in a great many cases the capacity to adapt is *almost entirely lacking*. The ordinary practice in psychological medicine in dealing with children is to attempt the alteration of environment, so as to minimise the problems and modify the difficulties for the child. With adults this is not as a rule possible, nor is it indeed very desirable, since it is hard to produce a permanent improvement in this way. The child, as it grows up, should learn to remove some of its own square corners, and the adult neurotic, provided he has reasonable intelligence, has always to do this if he is to be free of his difficulties. Put in this way, it is clear that a good many adults fly to alcohol because it saves them from feeling that they do not fit into life.

Psychological regression is the most important fact in the pathology of most psychoneuroses and in all cases of addiction. Retreat from the difficulties of life is permissible and advisable up to a certain point. Fairy-stories present life to children in a form which they can understand, and make-believe softens a great deal of the undue hardness of reality. We permit ourselves many forms of retreat in adult life; food, bed, holidays, books, and aspirin—all of these have their reasonable place in our scheme of life. The relief of pain or of tension is of real value for our efficiency and happiness. It is a perfectly admissible argument that alcohol has a place also in the life of the ordinary man. The difficult point to decide is just analysis of the type which Freud has called "psycho-analysis." In between these two extremes there are many analytical methods employed, which make use of the method of free association and of dream interpretation, but which are directed somewhat more by the physician than would be the case in psycho-analysis. For the majority of patients with whom we have to deal, this is adequate, and analysis conducted in this way is naturally quicker than by the orthodox Freudian method.

---

* A paper opening a discussion at the Society for the Study of Inebriety on Oct. 11th.

The method that one employs should, I believe, be the one that seems best suited to the individual case. The man whose trouble is primarily the outcome of an hysterical diathesis can probably be helped by the shorter methods. The man who is obsessional in type and whose addiction is part of his compulsive state will need a much more thorough-going analysis. The specialist may need to handle some of the more complicated cases. The general practitioner, while he has not the time and, very likely, not the necessary knowledge to carry out an elaborate analysis, can do a very great deal with the majority of his patients. A little knowledge of psychological mechanisms is so much better than none, and if we are content to let our patients do most of the talking and to listen ourselves, more can be accomplished than most people believe.

This is not the place to attempt any description of the methods of psychotherapeutic approach. I wish to emphasise, however, that with these patients, whether they be in their own homes or in institutions, we are doing less than we might if we are not setting out to find the cause of the illness, and to help them achieve their freedom. We can adjust environment considerably, but we cannot handle problems which are endopsychic without employment of some psychotherapeutic method.

The treatment of the addictions is, like the treatment of all other conditions, very much more easy and more satisfactory if it can be undertaken at an early stage of the illness. If the medical profession recognised the importance of dealing with alcoholism in its beginnings, before the habit is well-established, the results would be more rewarding. Unfortunately our undergraduate medical education does not teach us very satisfactorily to recognise the importance of psychoneurotic reactions. In an overcrowded curriculum, there seems to be little time to discuss the problems which lead up to disorders of the sex life, and to the misuse of drugs. The doctor who is treating such cases needs a great deal of insight and a great interest in the personality of his patient. He must be tolerant, and he must be willing to spend time. With this equipment the general practitioner, who already helps great numbers of incipient alcoholics, would find that he was able to help still more, and to produce more permanent results.

Prevention

The prevention of addiction is a more interesting and a more profitable subject even than its treatment. Ross's discovery of the relation of the anopheles to the spread of malaria has made it possible to get rid of that disease, though as yet we have not managed to carry out all the measures that should be undertaken. In the same way, armed with a considerable amount of knowledge as to the ways in which neurotic tendencies arise in the individual, it should be possible for us, in time, to produce a race of men and women sufficiently well-balanced and adjusted to have no need for the use of drugs in the wrong way. It should certainly be possible to eradicate these disorders, whose symptoms at present constitute so grave a social disease. In this country, education and the improvement in the standard of living have already done much to lessen the problem. As we train men and women, inside and outside the medical profession, to understand the causative factors in the emotional life of the individual, we shall be able to do still more. We need education, but not in the evils of alcohol. So much more can be done by emphasising the advantages and privileges of right living and right thinking, and by inculcating courage and the spirit of adventure.

There is a curiously true ring about the name "Band of Hope." It would be very good if they could be, in fact, bands of hope and courage. Too often, I fear, they have turned into bands of pessimism and of evasion. Children, passing through these organisations, have got a negative impression with regard to life; there has been over-emphasis on the symptom of alcoholism, and the tendency to seek safety has been increased instead of countered. It is a fundamental principle of modern education that, wherever it is possible, one should be positive rather than negative, and should tell people to do certain things rather than not to do others. If we are to help children through education to grow up to a life in which they will not need to take refuge in alcohol, it is, I believe, far better that we should stress the positive principles of living and touch on warnings and prohibitions in the lightest possible manner, if at all. If anyone is in doubt of the effects of prohibitions on the mind of the child and the adolescent, the situation which has arisen in America is informative. We must face these problems sufficiently thoroughly to be able to direct people in the right direction, so that we may say "do" instead of "don't."

The total abstinence pledge has been one of the greatest stand-bys of social reformers in the past. That, however, is also negative in its approach to the problem. There is nothing, in a promise not to drink alcoholic liquors, which fires the imagination. A new form of declaration might be very useful if it presented a picture of a free, courageous, and coöperative life. People who have been brought up as children to value their manhood and their freedom and their varying capacities are not likely to make bad use of them in later life.

Our prophylactic efforts must certainly be directed towards early childhood, for the root of the matter is there. Parental education is being undertaken on a much more widespread scale, and in a far more intelligent fashion. Throughout the country there are bodies like the Home and School Council and infant welfare organisations, which are helping parents to a better insight into their children's minds, and presenting them with wiser methods of dealing with the difficulties of childhood. Even the daily press has now taken up this propaganda, and quite often their effort is of value. The fact that journalists consider the matter of mental health in childhood to have news-value is an indication of the awakening interest of men and women in general. We in the medical profession have constantly to widen our field of work. Preventive work in mental disorder is as much within our field as the treatment of established disorder should be.

To sum up the points which I have tried to make in opening this discussion: The foundations of personality and character are laid in the first few years of life, before seven. Since there is always an emotional causation for addiction, it is essential that we should appreciate and investigate the "pattern of life" of the individual concerned. Treatment by environmental means, and still more by psychotherapy, can cure the patient. Wiser and more understanding treatment of the child in early days will obviate the necessity for that child in adult life to break down under the strain of circumstances and take refuge in alcohol or drugs.

THE GOLDEN AGE OF THE CRAFT OF SURGERY *

By J. R. Learmonth, M.B., Ch.M., F.R.C.S. Edin.
REGIUS PROFESSOR OF SURGERY IN THE UNIVERSITY OF ABERDEEN

I have had some difficulty in selecting a topic for this address, for my most recent interests have been minutely technical and therefore unsuitable. After consideration I decided to offer some observations on surgery as I envisage it; that this is the Golden Age of surgical craft. The particular aspects of the matter that I shall bring to your attention are two in number; the fact that the spirit of a sentence constantly on the lips of John Hunter made this age inevitable, and the mirroring of the age in biological research and in surgical education.

The saying to which I refer was a favourite observation of Hunter's a century and a half ago: "To perform an operation is to mutilate a patient we cannot cure; it should therefore be considered as an acknowledgment of the imperfection of our art." Even for the man who acted as Prologue to the Golden Age of Surgery this was an amazingly astute comment on the surgery of his time, and from its second half it is easy to realise that even in an age still barren of aid from the sister sciences, Hunter had a vision of the surgery of the future. At the present day the criticism has lost some of its significance. It is true that operations have multiplied, for since Hunter's day the abdominal cavity, the cranial cavity, and the thoracic cavity have capitulated to the surgeon, but many of the incursions of the surgeon's knife into previously inviolate territory are balanced by the withdrawal of other forms of disease from surgical treatment; one example of this tendency is the present practice of treating certain types of malignant disease by the application of radium. There is no doubt that in the future the labours of physicists will provide forms of treatment, and those of chemists synthetic substances, which will restrict still more narrowly the craft of the surgeon. The search for the panacea is as old as history; nowadays it has been abandoned, and the search is for selective therapeutic methods, which arm us more effectively against disease. Individually and collectively surgeons must welcome each such innovation, as Hunter himself would have done, even if it leads to jettisoning cherished surgical procedures.

The Background of Modern Surgery

While the treatment of disease is progressing but slowly toward a non-surgical ideal, operative procedures have been so perfected that little is left of the sting of Hunter's comment. At the present time our craft, and I use the word "craft" advisedly, is, it seems to me, in its hey-dey. For a century and more it has had a sure foundation in the finality of regional anatomy. It is steadily acquiring a buttress of ever-increasing strength in the rapidly accumulating knowledge of physiology. We are constantly gaining information about the life-histories of processes of disease, and since "how" matters little, we are more often turning our attention to "why." For nearly a century we have been able to operate without inflicting pain, and within the last few years chemistry has provided us with drugs for stilling pre-operative apprehension, often of almost as great moment. Above all, for three-quarters of a century we have been able to offer operation to our patients in the Lister-given security that with the dangers of the knife need not be considered the even greater dangers of infection. For technical purposes we have at our disposal an imposing armamentarium. Bacteriology has attained the position of a science, and with the unravelling of microbic problems has come an encouraging number of immunological and chemical methods of treatment. The physicist has been a major benefactor; he has provided us with instruments for bringing under direct view certain of the cavities of the body; he has enabled us to divide tissues without attendant loss of blood, and with the aid of Rontgen's rays we can visualise, directly or indirectly, a host of pathological conditions. The physiological chemist has evolved for us methods of assessing the functional capacity of many of the vital organs of the body, so that we can accurately estimate the severity of disease, and more important still, we can gauge not only the time for active interference, but also its desirable extent. In some quarters it is fashionable to decry the use of certain of these aids, but with such criticism I cannot agree. Nearly every one of them has tended to make surgical treatment safer for the patient, and whatever our intellectual attitude, we are not at liberty to dispense with the most trivial procedure that can be used to this end. "Brains," says Dr. Harvey Cushing, "are futile without technique," and we must give weight to the pronouncement of a man singularly gifted with both. Possibly, as has been recently written by Lord Moynihan, the surgeon of to-day may not be so dexterous as the surgeon of pre-anæsthetic days, when the time taken to perform an operation was the all-important factor. It appears to me that the increase in the armamentarium of the modern surgeon has more than compensated for the loss of some manual skill, although a pretty subject for debate would be the results obtainable by a surgeon of the old régime, had he available only anæsthesia and asepsis of all our present accessories.

Acquisition and Nature of the Art

Were surgery a craft alone, the setting that I have described should provide that success in its practice would be limited only by the situation and the extent of processes of disease. Manifestly, its limitations are narrower, and the explanation is to hand; surgery is also an art. The acquisition of surgical art is one of the most valuable products of experience; and in experience is included not only personal experience, but also familiarity with the writings and with the practice of the masters of our profession. To a fortunate few surgical judgment seems to come early and without effort. For the majority the development of surgical art is at first a conscious process, and each necessity for displaying it entails the deliberate weighing of all immediate and remote factors bearing upon the problem. As experience increases, decisions are reached by mental short-cuts, and to me the supreme intellectual satisfaction in the practice of surgery is the realisation, as occasion arises, that a decision which proves to be correct has required no laborious process of integration. That most

THE GOLDEN AGE OF THE CRAFT OF SURGERY *

By J. R. Learmonth, M.B., Ch.M., F.R.C.S. Edin.
REGIUS PROFESSOR OF SURGERY IN THE UNIVERSITY OF ABERDEEN

I have had some difficulty in selecting a topic for this address, for my most recent interests have been minutely technical and therefore unsuitable. After consideration I decided to offer some observations on surgery as I envisage it; that this is the Golden Age of surgical craft. The particular aspects of the matter that I shall bring to your attention are two in number; the fact that the spirit of a sentence constantly on the lips of John Hunter made this age inevitable, and the mirroring of the age in biological research and in surgical education.

The saying to which I refer was a favourite observation of Hunter's a century and a half ago: "To perform an operation is to mutilate a patient we cannot cure; it should therefore be considered as an acknowledgment of the imperfection of our art." Even for the man who acted as Prologue to the Golden Age of Surgery this was an amazingly astute comment on the surgery of his time, and from its second half it is easy to realise that even in an age still barren of aid from the sister sciences, Hunter had a vision of the surgery of the future. At the present day the criticism has lost some of its significance. It is true that operations have multiplied, for since Hunter's day the abdominal cavity, the cranial cavity, and the thoracic cavity have capitulated to the surgeon, but many of the incursions of the surgeon's knife into previously inviolate territory are balanced by the withdrawal of other forms of disease from surgical treatment; one example of this tendency is the present practice of treating certain types of malignant disease by the application of radium. There is no doubt that in the future the labours of physicists will provide forms of treatment, and those of chemists synthetic substances, which will restrict still more narrowly the craft of the surgeon. The search for the panacea is as old as history; nowadays it has been abandoned, and the search is for selective therapeutic methods, which arm us more effectively against disease. Individually and collectively surgeons must welcome each such innovation, as Hunter himself would have done, even if it leads to jettisoning cherished surgical procedures.

The Background of Modern Surgery

While the treatment of disease is progressing but slowly toward a non-surgical ideal, operative procedures have been so perfected that little is left of the sting of Hunter's comment. At the present time our craft, and I use the word "craft" advisedly, is, it seems to me, in its hey-dey. For a century and more it has had a sure foundation in the finality of regional anatomy. It is steadily acquiring a buttress of ever-increasing strength in the rapidly accumulating knowledge of physiology. We are constantly gaining information about the life-histories of processes of disease, and since "how" matters little, we are more often turning our attention to "why." For nearly a century we have been able to operate without inflicting pain, and within the last few years chemistry has provided us with drugs for stilling pre-operative apprehension, often of almost as great moment. Above all, for three-quarters of a century we have been able to offer operation to our patients in the Lister-given security that with the dangers of the knife need not be considered the even greater dangers of infection. For technical purposes we have at our disposal an imposing armamentarium. Bacteriology has attained the position of a science, and with the unravelling of microbic problems has come an encouraging number of immunological and chemical methods of treatment. The physicist has been a major benefactor; he has provided us with instruments for bringing under direct view certain of the cavities of the body; he has enabled us to divide tissues without attendant loss of blood, and with the aid of Rontgen's rays we can visualise, directly or indirectly, a host of pathological conditions. The physiological chemist has evolved for us methods of assessing the functional capacity of many of the vital organs of the body, so that we can accurately estimate the severity of disease, and more important still, we can gauge not only the time for active interference, but also its desirable extent. In some quarters it is fashionable to decry the use of certain of these aids, but with such criticism I cannot agree. Nearly every one of them has tended to make surgical treatment safer for the patient, and whatever our intellectual attitude, we are not at liberty to dispense with the most trivial procedure that can be used to this end. "Brains," says Dr. Harvey Cushing, "are futile without technique," and we must give weight to the pronouncement of a man singularly gifted with both. Possibly, as has been recently written by Lord Moynihan, the surgeon of to-day may not be so dexterous as the surgeon of pre-anæsthetic days, when the time taken to perform an operation was the all-important factor. It appears to me that the increase in the armamentarium of the modern surgeon has more than compensated for the loss of some manual skill, although a pretty subject for debate would be the results obtainable by a surgeon of the old régime, had he available only anæsthesia and asepsis of all our present accessories.

Acquisition and Nature of the Art

Were surgery a craft alone, the setting that I have described should provide that success in its practice would be limited only by the situation and the extent of processes of disease. Manifestly, its limitations are narrower, and the explanation is to hand; surgery is also an art. The acquisition of surgical art is one of the most valuable products of experience; and in experience is included not only personal experience, but also familiarity with the writings and with the practice of the masters of our profession. To a fortunate few surgical judgment seems to come early and without effort. For the majority the development of surgical art is at first a conscious process, and each necessity for displaying it entails the deliberate weighing of all immediate and remote factors bearing upon the problem. As experience increases, decisions are reached by mental short-cuts, and to me the supreme intellectual satisfaction in the practice of surgery is the realisation, as occasion arises, that a decision which proves to be correct has required no laborious process of integration. That most

---

* Abridged from the inaugural address of the chair of surgery, and delivered at the University of Aberdeen on Oct. 17th.

philosophic of surgeons, Sir Benjamin Brodie, put the matter thus:

> "I cannot well understand what I have observed to happen in myself without supposing that there is in the human mind a principle of order which operates without the mind itself being at the time conscious of it. You have been occupied with a particular investigation; you have accumulated a large store of facts, but that is all. After an interval of time, and without any further labour, or any addition to your stock of knowledge, you find all the facts you have learned in their proper places, although you are not sensible of having made an effort for the purpose."

It may be added that these words are applicable to the whole field of intellectual endeavour and not to surgery alone, although they have a special significance in the field of biological research.

The Complexities of Surgery

I do not wish to give you the impression that in this golden age of his craft a surgeon can be complacent; far from it. Knowledge of his own shortcomings, and perusal of the scientific literature of the world, preclude any such attitude. Indeed, his most present feeling must be one akin to despair at the multitude of problems that cry for solution. The complexity of the matter is increased by the fact that a surgeon rarely deals with a problem in pure biology. If he could put his hypotheses through the mill of mathematics, that infallible touchstone of some of our scientists: if he could ask the test-tube to deny or to affirm: if he could segregate each ponderable factor, and analyse it in the experimental laboratory, then his tasks would be far less weighty, his responsibilities enormously lighter. But the surgeon is a dealer, not only in processes of disease, but also in human affairs. For him each problem is coloured by human nature, and its solution varies with a host of economic, social, and personal peculiarities. Each adequate solution must outline a course of action that is understood by, and acceptable to, the patient and his friends. In short, although he may, and usually does, reach his opinions by a process of reasoning conducted in the vocabulary of his profession, in his practice he is debarred from stating his argument and his conclusions in scientific terms. He must translate his opinions into language that is intelligible to the laity, and in my experience the premisses of his argument are the hardest so to construe. He must be prepared for suggested alterations in his plans, on grounds other than surgical; he who has the faculty of accepting these graciously is assured of at least material success. It is fortunate that these complex aspects of his profession do not in the very least tend to overburden the surgeon. On the contrary, they provide for him an almost unique fascination, which compensates for the laborious attention to the routine of detail, with which much of his active work is of necessity occupied.

It is true that a surgeon must concern himself with the inexhaustible problems of particular sciences. Although he must constantly keep before him the desirableness of turning to practical account the discoveries of the laboratory, it does not by any means follow that he should discourage researches that at first sight seem merely academic, for there is hardly anything biological that is alien to surgery. As pieces are added to the biological mosaic, it is often found that scraps of information, hitherto irrelevant, become first fundamental and finally utilitarian. The dictum of Froude, that the only real knowledge is that which a man can use, when applied to biological knowledge, must carry two qualifications: the first, that another man may be able to utilise a seemingly unimportant fact; the second, that biological knowledge is not infrequently acquired out of sequence, so that in time it may be possible to place such a fact in its proper setting, and in this it may prove to be indispensably useful.

Of more significance to the surgeon is the fact that neither his training nor his duties fit him to investigate many of the basic problems of function, whether the function be normal or pathological. The medical curriculum of the surgeon does not provide him with a course in logic, so that he cannot indisputably write *quod erat demonstrandum* at the end of many of his theorems. He cannot be expected to master the minutiæ of biophysical and biochemical methods, so that in many cases he is unable to start his researches at the beginning. Most of all, perhaps, he is haunted by the thought that what may work out well enough in the test-tube, or in the experimental animal, may be fraught with danger for his patient. In my view, too much emphasis has been placed on the last possibility, for the sum of benefits derived from the application to mankind of observations made on animals has far exceeded the harm.

Specialisation

One result of the many additions to the craft of surgery has been the creation of surgical specialists. By restricting his work to it, a surgeon may hope to round out his knowledge of a special subject on a biological basis. One obvious danger in such an arrangement is that of too early specialisation, so that the surgeon suffers from a loss of perspective; my own view is that a young surgeon's angle of incidence upon his specialty should be a very obtuse one, and fortunately in this country that is likely to be the case. Another defect in early specialisation lies in a lack of any arrangement providing that restriction of practice to a given subject automatically implies proficiency in it. On the other hand, specialism has two undoubted advantages. One of these is the intellectual satisfaction derived from comprehensive knowledge of a given subject, an aspect of the matter on which the elder Kocher was insistent. The other is the undoubted gain to the patient, whose malady is cared for by a surgeon familiar with all its peculiarities. It has been my experience that specialists who have risen high in the profession, and who have gained and retained the respect of their fellow practitioners, are the most conservative of surgeons, and most unlikely to allow themselves to be unduly influenced by their special knowledge. One other point; we are at a professional cross-roads in this country as regards specialisation. I would like to urge that the planes of cleavage between specialties should be vertical, and not (as there is some tendency to make them) horizontal. I mean by this, that for purposes of specialism the body should be divided into a series of functional units, rather than into a series of systemic units. Under the latter system there would be a perpetual necessity for the correlation and interlocking of separate specialties. Under the former, not only would the surgeon be trained to treat not a particular pathological condition, but the patient; he would also be infinitely better equipped to contribute his bounden quota to the progress of hominal physiology. And if surgical specialties there must be, and so dividing walls, we must make it our business to see that the walls are low, so that each specialist has an unhampered view of the work of his fellows, and we must arrange that the paths converge at frequent intervals into clearings, where all surgical lore becomes common property. So much for specialism in relation to craft; it must be remembered that an at least equally important aspect of the matter concerns the patient as an individual. In assessing the influence of this aspect no craftsman-specialist can hope to approach the authoritative position occupied by the patient's family physician.

The Puzzle or the Quest

With so many tests for this and that at his disposal, there is a temptation for the student to regard clinical work—and that is the supremely important part of a surgeon's training—as an exercise in the solution of so many puzzles, which require for their solving only the placing of each report in its proper setting. I mention this tendency only to urge that it be resisted. It is true that no avenue of approach to a clinical problem should be neglected that provides a possible additional factor of accuracy in diagnosis and thus of safety for the patient. Sometimes the result of a particular test may be irrefutable but it is, I think, usual to find that when a doubt remains after the clinical examination has been completed and the results of tests are available, the view of the trained clinician proves to be correct. If a struggle must be joined with the temptation to rely overmuch on laboratory tests, the most powerful ally that can be called to one's aid is clinical imagination. Each problem must be investigated afresh, and not dismissed as identical with a former one. Even if the surgical problems seem similar, the personal problems most assuredly differ one from the other, and it is only by the maintenance of an unprejudiced mind that the various features of a case can be honestly appraised and those of significance selected. If this method be pursued, the study of a surgical problem, whether complex or apparently simple, becomes not so much a matter of deciding upon a diagnosis or upon some particular form of treatment, as an adventure in both hominal physiology and hominal psychology; and as such it must be approached with reverent determination. Great as have been the advances, much remains to be accomplished in this field, and each of us, whether student of surgery or teacher, must take up his appointed place in an expeditionary quest which will occupy the whole of his professional life.

Preventive Surgery

One other modern movement influences present surgical education. I refer to the rapid expansion of preventive medicine, which encourages the surgeon to devise measures for the prevention of conditions, to the relief of which he formerly devoted his operative ingenuity. In other words, to the surgeon's responsibility for the life, or the comfort, or the economic efficiency of his fellow men, is being added responsibility for his health. As to this, no one has put the obligation better than Montaigne, himself far from a friend to the profession. "Health is a very precious jewele, and the onely thing, that in pursuite of it deserveth, a man should not onely employ, time, labour. sweate and goods, but also life to get it; forasmuch as without it, life becometh injurious unto us." And let me add that by assuming responsibility for the health of individuals, a surgeon takes his share of a greater responsibility, that for the health of the nation.

Thus my final point has concerned this movement to eliminate the need for some of the activities of the surgeon, a movement sensed by Hunter's prophetic soul. And I may fittingly close this address by declaring the faith that is in me; that a century and a half of surgical endeavour has been directed to removing any grounds for his stricture—not yet a completed task. but one which surgeons are proud to think has never lacked continuity. To fit ourselves for this task is an inescapable duty, yet one which is in prospect alluring. and in execution entrancing.

THE ACTIVATION OF INSULIN

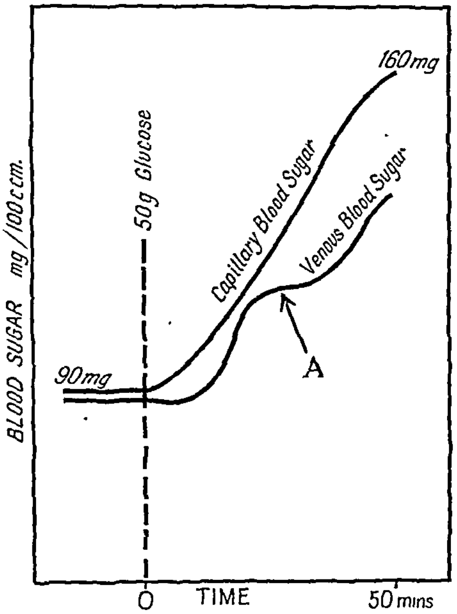
By H. P. Himsworth, M.D., M.R.C.P. Lond.

BEIT MEMORIAL RESEARCH FELLOW

(From the Medical Unit, University College Hospital, London)

The observation that a certain amount of insulin will ensure the retention in the body of a definite amount of carbohydrate is based on experiments with depancreatised. but otherwise normal, animals. But it is a commonplace of clinical medicine that in the diabetic patient insulin appears to vary in efficiency at different times. Thus the supervention of an infection may necessitate a temporary increase in the proportion of insulin to carbohydrate in the diet and the curing of the intercurrent illness may permit a corresponding decrease. Again, it is often found that if a diabetic is taking three meals of identical composition in the day, more insulin is required to prevent glycosuria after the morning meal than after either of the others. A rarer example of this decrease in efficiency is seen in those cases of diabetes which become resistant to insulin even when it is administered in huge doses. Indeed, the now common clinical observation that provided the caloric value of the balanced diabetic's diet is kept constant the carbohydrate may be trebled or quadrupled with little or no increase in the insulin dosage is a clear proof that in the diabetic at least the physiological concept of the glucose equivalent of insulin is not in harmony with clinical observation. A consideration of these and similar observations suggested that the question of variation in insulin activity required deeper analysis.

The problem was first approached through experiments on normal subjects. Results were obtained which proved that by altering the composition of the diet the efficiency of insulin in depressing the blood-sugar could be varied at will, and it was also demonstrated in the same experiments that there was a definite latent period after injection during which the insulin exerted no measurable action. In conjunction with these findings simultaneous blood-sugar curves in arterial and venous blood were performed under the same conditions and in them the phenomenon shown in the diagram was demonstrated. Earlier workers had shown that the degree of difference in sugar content of arterial and venous blood depended upon the amount of insulin present in the body. The sudden increase in the arterio-venous sugar difference at A must, therefore, mean an increase in the concentration of active insulin in the tissues at that point. There are two alternative possibilities. The first, that pancreatic insulin is suddenly secreted at the point A; the second that insulin is being continuously secreted by the pancreas in accordance with variations of blood-sugar. If the first possibility is correct then insulin as secreted by the pancreas is an active substance; if the second alternative holds, then insulin must have continued to be secreted by the pancreas the whole time since glucose was administered and have required the time between the ingestion of sugar and the development of A to acquire detectable activity. From various considerations we have come to the conclusion that insulin is secreted continuously and the time up to point A must represent the time taken for it to develop demonstrable activity. This reaction of activation must develop with increasing velocity and the analogous reaction of the activation of trypsinogen by enterokinase immediately suggests itself. Support is lent to the above interpretation of A by the observation that the interval before it occurred varied in accordance with the capacity of injected insulin to depress the blood-sugar. It was concluded from these results that insulin as we know it and as it is secreted by the pancreas is an inactive material which requires activating by some unknown substance for which we tentatively propose the name of insulin kinase.



Simultaneous blood-sugar curves in arterial and venous blood after administration of 50 g. glucose to a normal subject.

This theory throws light upon many hitherto inexplicable findings. Markowitz, Mann, and Bollmann [1] have shown that immediately after removing the liver from a dog insulin exerts its usual activity, but that several hours or more later large doses of insulin may exert no action on the blood-sugar. They suggest that the action of insulin on carbohydrate in the intact animal required some third factor. Althausen and Thoenes [2] have published results showing that in animals, during the stage of liver necrosis and fatty degeneration which follows poisoning with chloroform, there is a subnormal tolerance to a combined test of insulin and oral glucose; but that during the stage of liver regeneration, when the organ is full of young cells, there is a supernormal tolerance to the test. Reported cases of insulin-resistant diabetes are now numerous and in practically every one an abnormal state of the liver is recorded and some of the clearest cases have been those arising after thrombosis of the hepatic artery. In a case seen personally the progression of resistance was actually observed, a post-mortem was performed one hour and a quarter after death, gross liver damage was found, but the pancreas was macroscopically normal; microscopically no evidence of hydropic degeneration of the islet cells was found and granules were demonstrable in these cells by Bensley's stain.

From a consideration of these findings and our results the suggestion is put forward that insulin-kinase is produced in the liver. This obviously opens up many new possibilities in the pathology of diabetes. The question arises to what extent disease of the liver and the presence or absence of this new factor plays a part in the production of diabetes mellitus. Are there cases of diabetes which are due to disease of the liver and not to disease of the pancreas? Feeding with fat has been found to limit the production of insulin-kinase; does this throw light upon the ætiological relationship of obesity to diabetes? Is the syndrome of abdominal pain, vomiting, and rapid descent into coma with temporary insensitivity to insulin, which supervenes, apparently fortuitously, in balanced diabetics, due to impairment of liver function? And most important of all, can a substance be prepared from the liver which will remedy those conditions in which insulin-kinase appears to be deficient?

The details of the physiological results on normal subjects which have led to the formulation of this hypothesis are now being prepared for publication elsewhere. Work is proceeding on the various pathological questions that arise in the application of the theory to the analysis of diabetes, but evidence from clinical experience cannot soon be collected by one individual with conclusive certainty. This preliminary communication is therefore made in order to interest others in the attempt to regard diabetes and its problems from a new viewpoint.

OBSERVATIONS ON THROMBO-PHLEBITIS MIGRANS

WITH NOTES OF A CASE

BY ALEC B. WALKER, M.D., M.R.C.P. EDIN.
TUTOR IN CLINICAL MEDICINE, ROYAL INFIRMARY, EDINBURGH

THE type of thrombo-phlebitis first described in 1928 by Moorhead and Abrahamson [1] as thrombo-phlebitis migrans differs from other forms of "wandering" phlebitis in its extensive distribution and in the involvement of peripheral and visceral veins. The disease usually commences in either the superficial or deep peripheral veins with symptoms of inflammation, but later the veins of the lungs, abdomen, or more rarely, of the heart and brain, may be affected. Each fresh development is accompanied with fever and a moderate leucocytosis. The course, though prolonged, is relatively benign and the ætiology obscure.

Moorhead and Abrahamson described four cases, and Ryle [2] in 1930 recorded five, whilst others have been reported from time to time. A summary of these is given in the accompanying Table.

NOTES OF A CASE

A man, aged 47, was referred to the Royal Infirmary by Dr. A. Simpson, of Hawick, with the following history:—

In December, 1931, the patient complained of intense frontal headache and had a slight temperature. No sinus trouble could be detected. The pain gradually decreased in intensity and he was able to resume work in 14 days. After two weeks at work he was again confined to bed, this time complaining of intense pain in the left side of the chest

SUMMARY OF CASES OF THROMBO-PHLEBITIS MIGRANS REPORTED BY VARIOUS AUTHORS

Author.	Case	Sex.	Age.	Site of primary phlebitis.	Later sites of phlebitis (in sequence).	Ætiological factors.	Duration of illness.	Laboratory data.
Moorhead and Abrahamson	1	F.	55	L. arm.	L. arm, both lungs, abdomen, L. leg, R. leg, face.	—	1 year.	Blood culture negative.
"	2	M.	62	R. leg.	R. leg, L. leg, R. leg, L. lung, heart, R. lung, abdomen.	—	6 mths.	Blood culture, W.R. both negative. Complete X ray exam. negative.

* Test-meal normal. X ray examination for focal sepsis negative.

Pleurodynia was diagnosed at the time, there being no signs of involvement of either lung or pleura. As this was dying down, the patient developed similar intense pain in the calf of the left leg. Fomentations and opiates did not afford much relief. The pain was due to a phlebitis and after three weeks the symptoms and signs were sufficiently improved, and he began to move about again. The usual swelling took place and was very persistent. Gentle massage was commenced, but on Feb. 16th, 1932, the patient developed "definite signs of embolus" in the right side of the chest, just below and outside the nipple. In spite of two or three weeks in bed, during which the chest condition gradually cleared up, the swelling of the left leg remained.

On April 6th he was admitted for observation to the medical wards under the care of Dr. John D. Comrie as a case of multiple thrombo-phlebitis. His further history was uneventful until on April 16th, when in spite of absolute rest and elevation of left leg, he complained of acute pain on left side of chest with rapid respirations, increased pulse-rate, and slight temperature. Physical examination revealed an area of dullness posteriorly over the left lung base with diminished vocal resonance almost absent to breath sounds and definite pleuritic friction towards the axilla. The typical frothy blood-stained sputum of pulmonary infarction was coughed up. A hypodermic of gr. ¼ morphia plus gr. 1/100 atropine did not ease the pain appreciably, and on the following day a second similar injection was found necessary. Gradually the patient's condition improved, but on May 2nd he became very depressed and insisted on returning home. He was therefore discharged a few days later.

Previous History.—Operation for deviated septum some years ago, otherwise no illnesses.

State on Examination (April 6th).—A stout florid man. Height 5 ft. 9½ in. Weight 13 st. 1 lb. Swelling of left leg. Nervous system (report by Dr. E. H. Cameron): "Normal fundi and full vision. Right pupil rather larger than the left and neither reacts to light to any extent. The left reacts a little but the right not at all. Both pupils react to some extent on convergence." Knee-jerks elicited with difficulty. Apart from this nothing abnormal was found in the nervous system. The respiratory signs have been described above, and no other signs of disease were noted apart from the swelling of the left leg.

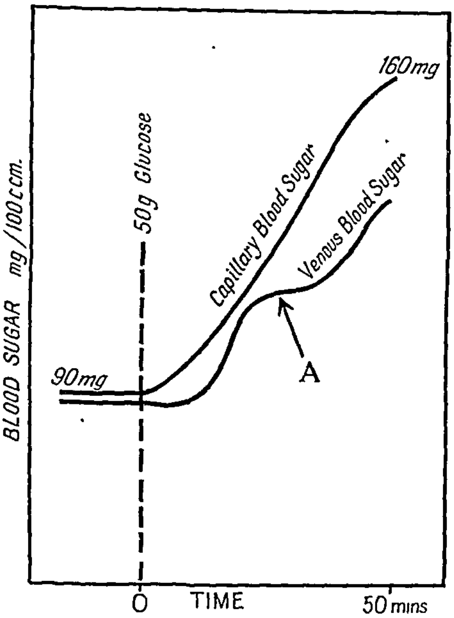
Laboratory Investigations.—Wassermann test negative. Blood-sugar 125 mg. per 100 c.cm. Urea nitrogen 13 mg. per 100 c.cm. Cerebro-spinal fluid: Wassermann test negative; cells 1 per c.mm.; colloidal gold 0001000000. Blood culture: growth of *B. alkaligenes* obtained.

Radiography (April 8th): Elevation and limitation of movement of left dome of diaphragm and adhesions of outer margin to parietal pleura. In the middle zone of the right lung field there is an area of obscurity associated with honeycombing suggesting existence of bronchiectatic dilatation at this point. Similar appearance towards base of left lung (Dr. D. White). April 30th: Pleurisy left side with effusion. There appears to be deviation of heart towards left side. ? Fibrosis at bases. An X ray examination for possible foci of sepsis was negative.

DISCUSSION

A glance at the Table shows that thrombo-phlebitis migrans usually commences in the peripheral veins of the upper or lower extremities, small sections of the superficial veins being generally first affected. In Case 9, however, the initial symptoms were due to phlebitis of the mesenteric veins, in Case 12 to phlebitis of the spermatic veins, and in Case 15 the first symptoms suggested venous cerebral thrombosis. The disease affects males and females of all ages, but is more liable to attack those in middle age. Of visceral lesions, pulmonary are the most frequent and both lungs may be affected at different times or repeated thromboses may occur in the same lung. Peripheral venous inflammation may occur without involvement of viscera, but in Case 9 visceral lesions only occur.

The case reported above presents the following detectable activity. From various considerations we have come to the conclusion that insulin is secreted continuously and the time up to point A must represent the time taken for it to develop demonstrable activity. This reaction of activation must develop with increasing velocity and the analogous reaction of the activation of trypsinogen by enterokinase immediately suggests itself. *Support is lent to the above interpretation* of A by the observation that the interval before it occurred varied in accordance with the capacity of injected insulin to depress the blood-sugar. It was concluded from these results that insulin as we know it and as it is secreted by the pancreas is an inactive material which requires activating by some unknown substance for which we tentatively propose the name of insulin kinase.



Simultaneous blood-sugar curves in arterial and venous blood after administration of 50 g. glucose to a normal subject.

This theory throws light upon many hitherto inexplicable findings. Markowitz, Mann, and Bollmann [1] have shown that immediately after removing the liver from a dog insulin exerts its usual activity, but that several hours or more later large doses of insulin may exert no action on the blood-sugar. They suggest that the action of insulin on carbohydrate in the intact animal required some third factor. Althausen and Thoenes [2] have published results showing that in animals, during the stage of liver necrosis and fatty degeneration which follows poisoning with chloroform, there is a subnormal tolerance to a combined test of insulin and oral glucose; but that during the stage of liver regeneration, when the organ is full of young cells, there is a supernormal tolerance to the test. Reported cases of insulin-resistant diabetes are now numerous and in practically every one an abnormal state of the liver is recorded and some of the clearest cases have been those arising after thrombosis of the hepatic artery. In a case seen personally the progression of resistance was actually observed, a post-mortem was performed one hour and a quarter after death, gross liver damage was found, but the pancreas was macroscopically normal; microscopically no evidence of hydropic degeneration of the islet cells was found and granules were demonstrable in these cells by Bensley's stain.

From a consideration of these findings and our results the suggestion is put forward that insulin-kinase is produced in the liver. This obviously opens up many new possibilities in the pathology of diabetes. The question arises to what extent disease of the liver and the presence or absence of this new factor plays a part in the production of *diabetes mellitus*. Are there cases of diabetes which are due to disease of the liver and not to disease of the pancreas? Feeding with fat has been found to limit the production of insulin-kinase; does this throw light upon the ætiological relationship of obesity to diabetes? Is the syndrome of abdominal pain, vomiting, and rapid descent into coma with temporary insensitivity to insulin, which supervenes, apparently fortuitously, in balanced diabetics, due to impairment of liver function? And most important of all, can a substance be prepared from the liver which will remedy those conditions in which insulin-kinase appears to be deficient?

The details of the physiological results on normal subjects which have led to the formulation of this hypothesis are now being prepared for publication elsewhere. Work is proceeding on the various pathological questions that arise in the application of the theory to the analysis of diabetes, but evidence from clinical experience cannot soon be collected by one individual with conclusive certainty. This preliminary communication is therefore made in order to interest others in the attempt to regard diabetes and its problems from a new viewpoint.

OBSERVATIONS ON
THROMBO-PHLEBITIS MIGRANS

WITH NOTES OF A CASE

By Alec B. Walker, M.D., M.R.C.P. Edin.
TUTOR IN CLINICAL MEDICINE, ROYAL INFIRMARY, EDINBURGH

The type of thrombo-phlebitis first described in 1928 by Moorhead and Abrahamson [1] as thrombo-phlebitis migrans differs from other forms of "wandering" phlebitis in its extensive distribution and in the involvement of peripheral and visceral veins. The disease usually commences in either the superficial or deep peripheral veins with symptoms of inflammation, but later the veins of the lungs, abdomen, or more rarely, of the heart and brain, may be affected. Each fresh development is accompanied with fever and a moderate leucocytosis. The course, though prolonged, is relatively benign and the ætiology obscure.

Moorhead and Abrahamson described four cases, and Ryle [2] in 1930 recorded five, whilst others have been reported from time to time. A summary of these is given in the accompanying Table.

NOTES OF A CASE

A man, aged 47, was referred to the Royal Infirmary by Dr. A. Simpson, of Hawick, with the following history:—

In December, 1931, the patient complained of intense frontal headache and had a slight temperature. No sinus trouble could be detected. The pain gradually decreased in intensity and he was able to resume work in 14 days. After two weeks at work he was again confined to bed, this time complaining of intense pain in the left side of the chest

SUMMARY OF CASES OF THROMBO-PHLEBITIS MIGRANS REPORTED BY VARIOUS AUTHORS

Author.	Case	Sex.	Age.	Site of primary phlebitis.	Later sites of phlebitis (in sequence).	Ætiological factors.	Duration of illness.	Laboratory data.
Moorhead and Abrahamson[1]	1	F.	55	L. arm.	L. arm, both lungs, abdomen, L. leg, R. leg, face.	—	1 year.	Blood culture negative.
,,	2	M.	62	R. leg.	R. leg, L. leg, R. leg, L. lung, heart, R. lung, abdomen.	—	6 mths.	Blood culture, W.R. both negative. Complete X ray exam. negative.
,,	3	F.	50	L. foot.	L. leg, thigh (several attacks), R. hand, L. hand, ? lung, L. arm, R. knee.	Marked pyorrhœa.	2 years.	Blood culture negative. *S. viridans* from teeth.
,,	4	F.	22	L. leg.	R. leg, sup. veins, abdomen and trunk, R. knee.	—	2 years.	Cultures from section of vein negative.
Ryle.	5	M.	23	R. leg.	R. and L. leg, R. foot.	Septic roots.	3 years.	W.R. negative. Diff. blood count and clotting time normal.
,,	6	M.	58	R. leg.	L. lung, R. leg, and abdomen.	—	4 mths.	Pleural effusion: R.B.C.'s, lymphocytes and polymorphs in about equal proportions.
,,	7	M.	Middle age.	L. knee.	L. lung, R. foot, L. leg and foot (5 attacks).	Dental sepsis. Antrum and frontal sinus.	6 weeks.	Blood culture negative. *S. viridans* from sputum.
,,	8	F.	53	L. leg.	Both lungs, L. leg, R. leg.	Tonsils unhealthy.	5 years.	Friedländer's bacillus and strept. and pneumococci from sputum.
,,	9	M.	49	Abdomen.	L. lung, R. lung.	—	4 mths.	Blood culture negative. Pleural fluid sterile. Widal negative.
Low and Cook.[5]	10	M.	22	R. leg.	L. thigh, L. foot, R. arm.	—	4 mths.	—
,,	11	M.	26	L. leg.	R. leg, ? abdomen.	Septic teeth.	4 mths.	W.R. negative. X ray abdomen, pelvis and thigh, negative.
Collier.[6]	12	M.	53	Spermatic vein.	R. lung, L. leg, R. leg, L. arm, R. arm, L. lung, abdomen.	—	—	Widal, negative.
Ellison.[7]	13	M.	6	L. leg.	Abdominal wall and side of chest, ? L. lung, R. leg.	Scarlet fever and infected mastoid.	6 weeks.	Hæmolytic strept. isolated from antrum.
,,	14	M.	10½	L. leg.	R. leg.	Scarlet fever.	5 weeks.	—
Barber.[8]	15	F.	37	Brain.	? Abdomen, R. thigh, L. thigh, R. arm.	Septic erosion in cervix uteri.	2 years.	W.R. neg.; bleeding time 1½ min. Coagulation time 3½ min. Blood Ca. 12 mg. per 100 c.cm.*

* Test-meal normal. X ray examination for focal sepsis negative.

Pleurodynia was diagnosed at the time, there being no signs of involvement of either lung or pleura. As this was dying down, the patient developed similar intense pain in the calf of the left leg. Fomentations and opiates did not afford much relief. The pain was due to a phlebitis and after three weeks the symptoms and signs were sufficiently improved, and he began to move about again. The usual swelling took place and was very persistent. Gentle massage was commenced, but on Feb. 16th, 1932, the patient developed "definite signs of embolus" in the right side of the chest, just below and outside the nipple. In spite of two or three weeks in bed, during which the chest condition gradually cleared up, the swelling of the left leg remained.

On April 6th he was admitted for observation to the medical wards under the care of Dr. John D. Comrie as a case of multiple thrombo-phlebitis. His further history was uneventful until on April 16th, when in spite of absolute rest and elevation of left leg, he complained of acute pain on left side of chest with rapid respirations, increased pulse-rate, and slight temperature. Physical examination revealed an area of dullness posteriorly over the left lung base with diminished vocal resonance almost absent to breath sounds and definite pleuritic friction towards the axilla. The typical frothy blood-stained sputum of pulmonary infarction was coughed up. A hypodermic of gr. ¼ morphia plus gr. 1/100 atropine did not ease the pain appreciably, and on the following day a second similar injection was found necessary. Gradually the patient's condition improved, but on May 2nd he became very depressed and insisted on returning home. He was therefore discharged a few days later.

Previous History.—Operation for deviated septum some years ago, otherwise no illnesses.

State on Examination (April 6th).—A stout florid man. Height 5 ft. 9½ in. Weight 13 st. 1 lb. Swelling of left leg. Nervous system (report by Dr. E. H. Cameron): "Normal fundi and full vision. Right pupil rather larger than the left and neither reacts to light to any extent. The left reacts a little but the right not at all. Both pupils react to some extent on convergence." Knee-jerks elicited with difficulty. Apart from this nothing abnormal was found in the nervous system. The respiratory signs have been described above, and no other signs of disease were noted apart from the swelling of the left leg.

Laboratory Investigations.—Wassermann test negative. Blood-sugar 125 mg. per 100 c.cm. Urea nitrogen 13 mg. per 100 c.cm. Cerebro-spinal fluid: Wassermann test negative; cells 1 per c.mm.; colloidal gold 0001000000. Blood culture: growth of *B. alkaligenes* obtained.

Radiography (April 8th): Elevation and limitation of movement of left dome of diaphragm and adhesions of outer margin to parietal pleura. In the middle zone of the right lung field there is an area of obscurity associated with honeycombing suggesting existence of bronchiectatic dilatation at this point. Similar appearance towards base of left lung (Dr. D. White). April 30th: Pleurisy left side with effusion. There appears to be deviation of heart towards left side. ? Fibrosis at bases. An X ray examination for possible foci of sepsis was negative.

DISCUSSION

A glance at the Table shows that thrombo-phlebitis migrans usually commences in the peripheral veins of the upper or lower extremities, small sections of the superficial veins being generally first affected. In Case 9, however, the initial symptoms were due to phlebitis of the mesenteric veins, in Case 12 to phlebitis of the spermatic veins, and in Case 15 the first symptoms suggested venous cerebral thrombosis. The disease affects males and females of all ages, but is more liable to attack those in middle age. Of visceral lesions, pulmonary are the most frequent and both lungs may be affected at different times or repeated thromboses may occur in the same lung. Peripheral venous inflammation may occur without involvement of viscera, but in Case 9 visceral lesions only occur.

The case reported above presents the following features. Severe and persistent headache with malaise and pyrexia suggesting venous cerebral thrombosis (see Case 15) and later thrombo-phlebitis of left lung, left leg, right lung, and left lung again, in the order mentioned. The symptoms and signs in the right lung may, however, have been due to an embolus dislodged from left leg by too vigorous massage.

Campbell and Morgan[3] report an unusual case of multiple thrombosis in which the evidence suggests thrombosis affecting the posterior cerebral arteries. Coombs[4] describes a case and mentions others in which there is reason to suspect coronary thrombosis. These though similar in many respects to the cases described by Moorhead and Abrahamson[1] differ in that the arterial tree is also affected by the disease process, and are therefore not included in the Table.

The ætiology is still obscure. It has been sought to associate the condition with influenza, but in no case was a history of such infection obtained. It is more likely that those cases of thrombo-phlebitis *migrans with initial symptoms of cerebral thrombosis* are, in the early stages, diagnosed as influenza in error. The severity and persistence of the head pain in thrombo-phlebitis migrans is of help in making a differential diagnosis.

In Cases 5, 7, 8, 11, and 15 (?) there was reason to suspect the influence of chronic streptococcal focal sepsis, but in the others no evidence to support such a theory was obtained. No specific organism has been isolated, and blood cultures have been consistently negative. There were never signs of septicæmia, and Ryle concludes therefore that "if focal infection is to be regarded as of ætiological importance, the phlebitis must be due to a bacteriæmia rather than a true septicæmia." Cases 13 and 14 followed shortly upon an attack of scarlet fever, but both are atypical in that the thrombo-phlebitis affecting both legs was very extensive, spreading upwards over the abdominal wall and chest. It is questionable whether these two cases, interesting and unusual as they are, ought really to be described as thrombo-phlebitis migrans.

Syphilis also is evidently not a factor. In the above case the ocular phenomena, though not conforming to true Argyll Robertson pupils, suggested the presence of syphilitic infection, but the laboratory findings were all negative.

It is possible that the main ætiological factor is the "soil"—i.e., the condition of the patient—the disease depending on some obscure alteration in the chemico-physical composition of the venous blood (McDonagh[9]).

I have to thank Dr. Comrie for permission to publish the notes of the case.

DARLINGTON HOSPITAL CHILDREN'S WING.—By the efforts of the Darlington Rotarians, spread over the last two years, a children's wing, which has cost £12,000, has been added to Darlington Memorial Hospital.

THROMBO-PHLEBITIS MIGRANS

BY NORMAN KLETZ, M.B. MANCH., M.R.C.P. LOND.

PHYSICIAN TO ANCOATS HOSPITAL; PHYSICIAN AND HON. PATHOLOGIST TO STOCKPORT INFIRMARY; VISITING PHYSICIAN AND CONSULTING PATHOLOGIST TO PARK HOSPITAL, DAVYHULME

Thrombo-phlebitis migrans is characterised by a thrombo-phlebitis occurring without any pre-existing affection of the veins, without any gross cause, and presenting a tendency to reappear in various situations. It particularly involves the superficial veins of the extremities, but not infrequently there are associated thromboses of veins of the internal viscera. By no means a rarity, it nevertheless seems to be a relatively uncommon affection. The fact of venous thrombosis developing in relation to acute infective and debilitating conditions is too well established to justify any special consideration. The interest of thrombo-phlebitis migrans lies in the peculiar migratory tendency of the recurrent clottings, in the prolonged period over which such clottings occur and the absence of any causative factor. Though the prognosis has been regarded by most writers as uniformly favourable, this is not so. Lipschitz[1] records one fatal case, and in the small series about to be described there was also a fatal issue. Apart, however, from any question of danger to life, thrombo-phlebitis migrans may involve a prolonged period of incapacity and suffering. It is, therefore, worthy of consideration especially from the point of view of possible treatment.

Moorhead and Abrahamson[2] described several cases, and a further series has been published by Ryle.[3] Carmichael Low and Cook[4] also described two cases occurring in Asiatics. Both cases had a history of dysentery and gonorrhœa, but no causal relationship is claimed or suggested by these authors.

So far as the general clinical features of the condition are concerned these are well summed up by Harkavy[5] as follows:—

1. A tendency to involve superficial veins especially of the upper and lower extremities.
2. A decidedly segmental distribution with healthy vein intervening.
3. A progressive spread which is usually accompanied by moderate fever.
4. A lesion having the appearance of an erythematous, fusiform, nodular mass, sensitive to touch; œdema may, or may not, occur.

There is, however, here no mention of thromboses of veins of the internal viscera upon which Moorhead and Abrahamson, and Ryle rightly lay much emphasis. This last author also quotes cases of similar visceral phlebitis described by Campbell and Morgan,[6] and Coombs.[7] A further point of interest is the association of thrombo-phlebitis migrans with thrombo-angiitis obliterans, as recorded by Buerger[8] and many others.

As has been already indicated, the ætiology of this peculiar wandering thrombo-phlebitis is still obscure. Cases occurring in relationship to syphilis, tuberculosis, and gout are described, and references to these are given by Moorhead and Abrahamson, but in the type of case here under discussion no definite causative factor has been adduced. The general features suggest a bacterial cause, presumably blood-borne from some cryptic focus. This is the view put forward by Vaquez and Laconte,[9] and others. Naturally, if this be so, as Ryle points out, the process must be one of bacteriæmia and not septicæmia, in view of the long duration of the illness and the almost invariable recovery. The fact that in no case has a positive blood culture been obtained does not minimise the probable correctness of the suggested mechanism. In a low-grade periodic bacteriæmia culture of the blood is, of necessity, speculative, and could only reasonably be expected to prove positive if it were possible to obtain the blood either immediately prior to or at the exact point of onset of an area of phlebitis. Equally, as any infective factor concerned must be of a low-grade virulence, one would not anticipate any definite leucocytic response. Unless and until it is possible to establish the cause of a thrombo-phlebitis migrans, treatment must, as Ryle frankly puts it, be merely "expectant and symptomatic." In a condition liable, at best, to a prolonged course, and not entirely devoid of risk to life, such a state of affairs is obviously unsatisfactory.

It has, therefore, been thought of value to publish the following cases: firstly, to add to the relatively small number hitherto described, thereby focusing attention upon an interesting clinical condition; secondly, as affording some support to the view of blood-borne infection as the probable cause. Finally, whilst realising to the full the undesirability of making dogmatic deductions as to the efficacy of any therapeutic measure on the basis of a few cases, nevertheless it would appear that certain procedures adopted in certain of these cases had a favourable influence.

CASE REPORTS

CASE 1.—A commercial traveller, aged 30, first seen Dec. 30th, 1927. In 1914 he had some affection of the right ankle-joint which was, for a time, thought to be tuberculous. This joint was ultimately operated upon but not proved to be tuberculous. Served in the army 1918 and 1919. In 1920 he had two attacks of phlebitis in the right calf. After a free period of a year had several recurring areas of phlebitis in the right leg. In 1925 he had several of the thickened areas removed. From this time onwards he had frequent recurrence of areas of phlebitis with "reddening of the skin" in both legs, but more particularly the right.

On examination in December, 1927, general physical examination was negative apart from some infection of the teeth. As part of a general investigation a careful cultural examination was made of nose, throat, urine, fæces, and sputum. There was a copious growth of hæmolytic streptococci from nose and throat. A vaccine was prepared from these organisms and a course of injections was given.

There had been no further recurrence of phlebitis when the patient was last seen in 1930, though some varicosity of the superficial veins had now developed, presumably secondary to repeated venous obstruction.

CASE 2.—Miss A., aged 49. Seen originally August 7th, 1929. During Whitweek in 1929 she started to have pain in the right leg from the knee to the groin, "there was a red ribbon up the leg." This gradually settled, but was followed by a severe pain under the right shoulder-blade with raised temperature but no hæmoptysis. This was diagnosed as pleurisy, though more probably a pulmonary phlebitis. The patient was then in a nursing-home for two months with recurring phlebitis. A full bacteriological examination was made and the blood was cultured. As the outcome of these examinations a vaccine was prepared and administered.

On examination on August 7th, 1929, no active phlebitis was found, but there was slight œdema of the left leg below the knee. As the condition appeared to be quiescent, no special treatment was undertaken. Two months later the patient was seen again. There had been recurring phlebitis of both legs, and at the time of this examination there was active change in the superficial veins of the right leg and enormous œdema of the left as high as Poupart's ligament. The bacteriological possibilities were once more explored without any suggestive result. Teeth and sinuses were, of course, radiographed.

Believing the condition to be of infective origin, and encouraged by the frequent success over a long period of trial of intravenous protein injections in some arthritic cases of probable infective origin, it was considered justifiable to try the same method in this case. Six injections of a *Bacillus coli* vaccine were given intravenously, diluted with saline solution, at intervals of five days, the dose being graduated so as to secure a good general reaction lasting about 10 hours.

The active phlebitis disappeared and no further clottings took place. All went well until March, 1931—a much longer period of freedom than any hitherto—when the patient was seized with severe headache, fever, aphasia and weakness, and incoördination of the right hand. The diagnosis of a cerebral thrombosis due to active phlebitis was made. This attack passed off in about three weeks, though a slight difficulty of speech remained.

In June, 1931, a further cerebral thrombosis occurred with rise of temperature to 102°. This, unfortunately, proved fatal.

Though clearly the condition was not cured, it does appear reasonable to suggest that the intravenous protein injections had a favourable, if temporary, influence on the course of the illness.

CASE 3.—Mr. B., aged 50. Seen in 1930. He had previously been perfectly healthy. Some time before being seen he had been involved in a motor accident, though he had not himself suffered any appreciable physical damage. About a month later he started with small patches of phlebitis in the superficial veins of both legs. This recurred with extreme frequency for two months or so prior to his being seen. No cause was found for it on physical examination, and it was decided to try a course of intravenous protein injections of *B. coli* vaccine. This was done; six doses were given. No further thrombo-phlebitis occurred, nor has there been further trouble.

CASE 4.—Mrs. C., aged about 30. Seen in 1930. This patient had a long gynæcological history with repeated operation but had achieved a successful labour, since when there had been recurring thrombo-phlebitis of the superficial veins of the upper extremities, particularly round the elbows. There was no clinical evidence of any active uterine or pelvic infection.

Bacteriological investigation was carried out and a pure culture of streptococci isolated from the cervix uteri. A vaccine was prepared and given in graduated doses. The phlebitis present settled down and there has been no further trouble.

It might be thought that the relationship to pregnancy and uterine infection does not fulfil the requirements of the condition under consideration, but the migratory features, the unusual involvement of the upper extremities, and the distant low-grade source of infection seem not only to justify inclusion of this case, but also to support the mechanism of causation of thrombo-phlebitis migrans suggested above.

CASE 5.—Mrs. D., aged 52. Seen May 29th, 1930. Has had recurring phlebitis in superficial veins of the legs since February, 1930. No injury or previous acute illness.

On examination patches of thrombosed veins on the inner aspect of both thighs. No evidence of varicose veins. Teeth infected but no other definite abnormality anywhere. This case was fully investigated as to blood count, blood culture, blood calcium, red cell sedimentation rate, coagulation time, &c., without any suggestive result. Full bacteriological investigation was also carried out; no deduction was made from this. The infected teeth were extracted, and as no further clotting had developed, the patient was allowed to go home two months later.

About a year afterwards she was readmitted to hospital with an obvious carcinoma of the stomach. No further phlebitis had occurred since the time of previous admission. No suggestion of possible carcinoma had then been present. In spite of the serious disease subsequently revealed, it seems more probable that dental infection was the cause of the phlebitis.

CLINICAL AND LABORATORY NOTES

AN ANOMALY OF THE COLON

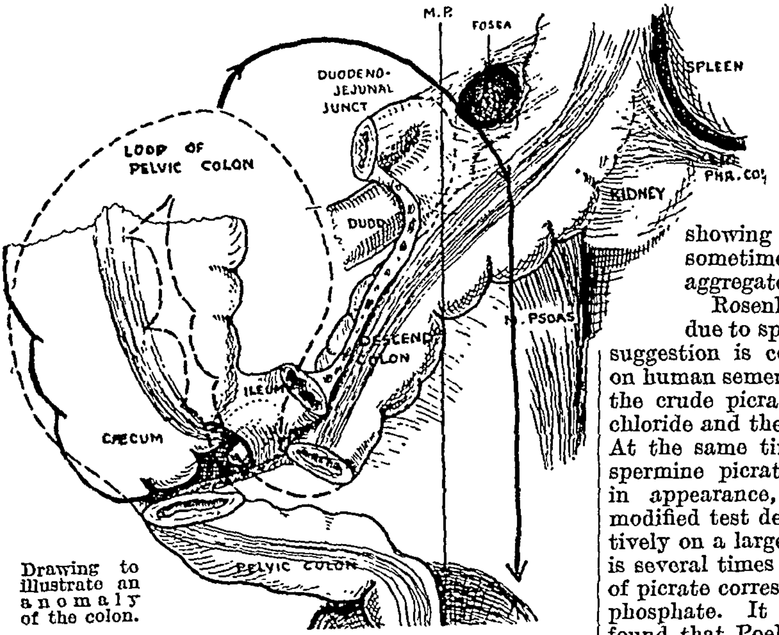
By G. Elliot Smith, M.D. Sydney, F.R.C.P. Lond., F.R.S.

PROFESSOR OF ANATOMY IN THE UNIVERSITY OF LONDON, AT UNIVERSITY COLLEGE

The note by Dr. H. W. Benham on An Unusual Case of Volvulus, in The Lancet of August 13th, prompts me to put on record another case involving gangrene of most of the small intestine and part of the large intestine which came under my notice in 1905. The case impressed me at the time not only because, so far as I could discover, it was unique, but also because it illustrated the practical importance of anomalies of the colon, of which I saw a number of striking illustrations in the course of my work in Egypt. Hence I prepared a careful report of the case, accompanied by a drawing to make clear the remarkable condition which I found. This was posted to England for publication, and I never heard any more of it.

During the summer of 1905, in the absence of the professor of pathology from Egypt, I was performing the post-mortems at the Kasr-el-Ainy Hospital. One evening in the club in Cairo I was struck by the appearance of one of the native Nubian servants who seemed to be desperately ill, and I suggested to the secretary of the club that the man should be sent off. The waiter replied that as he only had another half-hour of duty he would see it through.

On going to the post-mortem room at the hospital next morning I saw this man's corpse on the table, and found on examination a most remarkable state of affairs. He had an excessively long pelvic colon measuring 83 cm. in length, which was only 1 cm. less than the longest recorded case I was able to find at that time. The long loop of pelvic colon had slipped up the right side of the abdomen and then fallen to the left over the root of the mesentery. It was sufficiently long to pass down the left side of the abdomen into the pelvis. This heavy loop of colon, dragging on the mesentery, had led to the strangulation of the blood-vessels in the mesentery, causing gangrene of the greater part of the small intestine below the duodeno-jejunal junction, and it had also compressed the blood-vessels supplying the pelvic colon itself, so that it also was in a gangrenous condition.



Drawing to illustrate an anomaly of the colon.

Having lost the original drawing of this condition, perhaps I may reproduce here, for the purpose of elucidating the causation of the gangrene, a drawing of a peculiar anomaly of the colon which was found by two of my students three years afterwards, and published in the *Journal of Anatomy and Physiology* in 1909. Although in this second case the position of the pelvic colon was quite abnormal, it illustrates how it moved up on the right side of the abdomen to reach the level of the duodeno-jejunal junction. In this drawing I have inserted an arrow to indicate the subsequent course of the displacement which occurred in the fatal case to which I have referred.

A MODIFICATION OF BARBERIO'S TEST FOR HUMAN SEMINAL STAINS

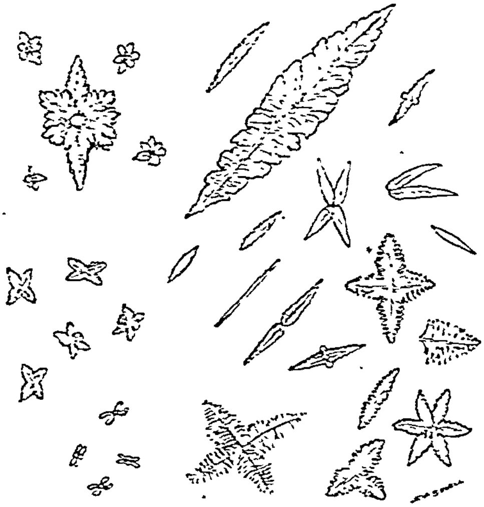
By G. A. Harrison, M.D. Camb.

READER IN CHEMICAL PATHOLOGY, UNIVERSITY OF LONDON; CHEMICAL PATHOLOGIST TO ST. BARTHOLOMEW'S HOSPITAL

As originally described Barberio's test is performed by adding a saturated aqueous or alcoholic solution of picric acid to an aqueous extract of the seminal stain. After a few minutes the mixture is examined microscopically for the crystals which vary in size (5–20 μ) and shape; these crystals have been described as rhombic needles; as resembling Charcot-Leyden crystals; as ovoid or needle-shaped with rounded ends; as sharp-ended needles; as rhombic prisms often with a refrangent line at their equator; as crosses and stars; or even as small ovoid bodies showing Brownian movement. They are sometimes twinned, and also form drusy aggregates.[1 4 5]

Rosenheim [6] suggested that the crystals were due to spermine picrate. I have shown that this suggestion is correct by performing Barberio's test on human semen on a relatively large scale, separating the crude picrate and converting it into the hydrochloride and then into the characteristic phosphate.[2 3] At the same time the crystals are probably *impure* spermine picrate, first because they vary so much in appearance, and secondly because, when the modified test described below is carried out quantitatively on a larger scale, the weight of picrate crystals is several times greater than the theoretical quantity of picrate corresponding to the final yield of spermine phosphate. It is interesting to note that Barberio found that Poehl's spermine was the only substance that gave picrate crystals resembling those obtained from human semen. But he observed that after heating Poehl's spermine to 100° F. for one and a half hours no crystals were obtained with picric acid, whereas dried semen would stand a temperature of 150°F. (but not of 200°) for one hour and still give a positive reaction. In view of Rosenheim's observation that the commercial material sperminum Poehl contained only traces of spermine, these experiments on the effect of heat are of no importance.

The obvious disadvantages of the test as originally described are that a search has to be made for crystals in a mass of amorphous precipitate of protein, and that the conditions for carrying out the reaction are not well defined. I believe that these disadvantages have largely been overcome in the modified method.



Composite drawing under the microscope of crystals of impure spermine picrate obtained in modified Barberio's tests.

THE MODIFIED TEST

The seminal stain is extracted with trichloracetic acid which removes spermine and other substances, but leaves behind the proteins. The cleared extract is precipitated with picric acid, and the crude spermine picrate is crystallized under conditions determined by experiment. The details are as follows:—

A portion of the cloth about 1 × 1 cm. is cut out from the stain and pushed to the bottom of a tapered centrifuge tube; 1 c.cm. of 2·5 per cent. trichloracetic acid is added, and the tube is shaken at intervals. After standing for about one hour the tube is centrifuged, and the supernatant fluid is decanted. This fluid is generally clear, but may be slightly opalescent. An equal volume of a saturated aqueous solution of picric acid is added, when a precipitate forms if spermine is present. Certain other substances, however, may also give a precipitate (amorphous), so that the appearance of a precipitate does not necessarily mean that the reaction is positive. The mixture is placed in a boiling water-bath for a few minutes till solution is complete. The flame is turned out, and the tube is left to cool slowly in the bath. When cool the contents of the tube are centrifuged if necessary, and the precipitate is examined under the microscope. If crystals are observed the reaction is positive, but amorphous particles are of no significance. If a relatively *copious* precipitate is obtained which is amorphous, it may be due to the concentration of spermine picrate being relatively high. In that case the contents of the tube are diluted with one or more volumes of a mixture of equal parts of 2·5 per cent. trichloracetic acid and saturated picric acid (but *not* with water), heated and cooled as before. This, however, is rarely necessary if the test is carried out as described.

The yellow crystals vary considerably in size and shape. They may be acicular, either single or as crosses or in stars, or they may be lenticular, often with a refrangent line at their long axis, and resembling spermine phosphate crystals morphologically. Quite frequently these crystals have an irregular outline; there may be a single bulge at the centre, or the whole crystal may have a "feathery" appearance; they may be twinned. Some of the forms observed are illustrated in the Figure.

CONTROL TESTS

The reaction has been applied to cloth stained with the following substances: human whole blood, oxalated plasma, serum, urine, fæces, sputum, pus (staphylococcal, pneumococcal, and pus from a pancreatic cyst), and cow's milk. Some of the samples of pus gave a slight amorphous precipitate, but no crystals. All the other materials gave no precipitate and no crystals. The nasal discharge on used handkerchiefs also gave negative results, as did a solution of tribasic calcium phosphate in 2·5 per cent. trichloracetic acid.

DISCUSSION

I believe that in the past negative results may sometimes have been obtained with Barberio's test owing to ignorance of the fact that too concentrated an extract of a seminal stain may give an amorphous precipitate.

Obviously the time allowed for extraction of the stained cloth will influence the concentration of spermine in the final extract. This factor has been checked by putting up a known volume of semen, dried on linen, in 10 volumes of 2·5 per cent. trichloracetic acid, taking out one volume at different intervals of time and carrying out the prescribed test. At first (ten minutes to one hour) good crystals were obtained, but after one hour the precipitate was amorphous. When the tubes containing the amorphous precipitate were suitably diluted with a mixture of equal parts of 2·5 per cent. trichloracetic acid and saturated picric acid (dilution with water was unsuccessful), heated and cooled as before, a crystalline picrate was obtained.

Clearly, the quantity of semen in a seminal stain is unknown. Moreover, the type of cloth may influence the rate of extraction by the trichloracetic acid, and again the concentration of spermine in the semen of different individuals certainly varies. These and other factors cannot be controlled properly, but I am of the opinion that the modified test is a distinct improvement on the original test, and that it is likely to yield a higher percentage of positive results with true seminal stains. There must still be an element of doubt when dealing with an unknown stain as to whether a negative result can be regarded as reasonable proof of the absence of semen from that stain, but at the time of writing false positive and false negative results have not been encountered in examining stains of known origin.

I am indebted to the Medical Research Council for a grant towards the expenses of this work.

CEREBELLAR SYNDROME AND NYSTAGMUS IN MIGRAINE

BY WILLIAM PHILLIPS, B.Sc., M.B. WALES
JUNIOR ASSISTANT IN THE MEDICAL UNIT, THE WELSH NATIONAL SCHOOL OF MEDICINE

A MAN who had always enjoyed good health began at the age of 28 to suffer from attacks of giddiness. At first these were mild, each lasting for perhaps not more than a minute; they recurred, however, several times a day. There might be no attacks for three or four days, but sometimes they would persist for several successive days. They gradually became more frequent and longer in duration, and, about a month after the onset of the trouble, the giddiness became associated with headache setting in a few minutes after the vertigo was experienced. The clavus—a severe shooting pain—was habitually to the outer side of the right orbit and spread mainly upwards to the right frontal, and outwards and backwards to the right temporal regions. Occasionally, in very severe attacks, it would extend as far back as the right occipital region, but the left side of the head was never affected.

These attacks of hemicrania, especially when severe, were often accompanied by diplopia, and at the beginning of each attack other visual disturbances were almost constantly present, although variable in degree.

The fully developed teichopsia were spontaneously described by the patient as follows: "Blackness comes in from each side, yet I can read print. Looking up, a very bright light surrounded by darkness appears, and, after a few seconds, oscillates up and down. It disappears suddenly, the brightness in the centre becoming replaced by blackness, leaving a ring of light." A few seconds after the onset reading was impossible. On inquiry it appeared that nothing suggestive of castellation figures or of fortification spectra were observed, but black non-scintillating scotomata were frequently seen. In addition, "floating bubbles of light, dodging in and out," scintillating and appearing chiefly in the upper half of the visual field, were seen, not only during, but also, in bright daylight, between the attacks.

The attacks steadily increased in severity, lasting half an hour to several hours in the daytime, and, if unrelieved by the evening, only ceasing on going to bed. Six months after the onset of his symptoms he began to experience a feeling of falling forwards whenever he stooped, but he never actually fell. From the beginning of his illness he had frequently experienced trembling in his left leg, and now he began to have a feeling of stiffness in that limb, and later, cramp followed by weakness persisting for some weeks at a time. Although he could not recall anything which suggested a precise relationship between these attacks of weakness and the attacks of migraine, it would seem that they were of the nature of the hemiplegic or monoplegic periodic palsies which very occasionally occur in migraine.[1]

Nine months after the commencement, his symptoms had become so severe that he was obliged to give up work. No improvement occurred, and three months later he came under the care of the medical unit at Cardiff.

Usually he felt depressed for a day or so before an attack, markedly so before a very severe one, and in this way he became aware that an attack was impending. He felt sick during almost every attack but vomited on two occasions only, and then the headache was unusually severe; it is noteworthy that the headache was thereby relieved. The patient stated that the attacks were more frequent and more violent when he was tired or worried, or after he had been reading or taking beer. He found that all his symptoms were aggravated by the erect posture and relieved by lying down, and especially by sleep. He did not suffer from any disturbance of appetite or from any unusual constipation.

The above twelve months' history is one typical of migraine. The patient, although he had always been fairly healthy, was of a very nervous disposition, and tended to worry excessively over small matters. Slight deafness in both ears had followed several severe "colds" about six years before the onset of his migraine. For the two years preceding the beginning of the illness, his occupation had exposed him to considerable damp, and during this period the joints of the little finger of each hand became chronically swollen, painful, and stiff. In this connexion it is interesting to recall that an association between various joint conditions and migraine has frequently been pointed out. Gowers[2] stated that a family history of gout was rarely absent in the worst cases; Jones[3] found that migraine had, for years in some cases, been present before the appearance of rheumatoid arthritis, while Hughlings Jackson[4] called attention to the existence of a close connexion between migraine, chorea, and rheumatism, and particularly to its more frequent association with chorea rather than rheumatism without chorea, in that chorea indicates cerebral involvement.

On inquiring into the patient's family history, it was found that a maternal aunt was a sufferer from attacks of typical migraine, with hemicrania ending in vomiting, and relieved only by sleep. His mother, too, had suffered for many years from severe headaches, although not hemicranial, and not associated with nausea or vertigo. One sister had died of chorea.

The patient was found to be well-built, well-nourished, and mentally alert, with arteries a trifle thickened for his age, and a systolic blood pressure of 145 mm. Hg. The thoracic and abdominal viscera showed nothing of note, and his Wassermann reaction proved to be negative. The deep and superficial reflexes were all normal, and no sensory loss of any kind, superficial, deep, joint, or vibration, could be detected.

He stated that at times his left arm got easily tired and felt weak, but examination never detected any muscular weakness in either the arms or the legs. This again was possibly of the nature of the monoplegic attacks to which reference has already been made. During the attacks of migraine, walking was practically impossible. If he attempted to do so, he would hold his head with both hands, and, leaning forwards, would stagger about in an alarming fashion. Even standing was extremely difficult on account of the giddiness. Between the attacks, however, the gait was normal, no peculiarity of attitude persisted, there was no Rombergism, and no incoördination could be detected in the arms. There was no evidence of hypotonia, no dysdiadochokinesia, and no defects in speech.

Eye signs, however, were most conspicuous. The pupils were normal, but nystagmus was particularly prominent, very persistent, and obvious even on a casual glance at the patient. He himself was aware of the eye movements and remarked that he could "put up with the headaches and giddiness if only his eyes would keep still." The nystagmus was chiefly lateral, and consisted of quick fine jerks, rather more marked and rapid on looking to the left than to the right, and at times increased in rapidity until the movement became almost a tremor. There was neither blepharospasm nor intolerance of light. In the absence of headache the nystagmus was much less marked, and then was usually only evident on looking to the left.

In addition to the nystagmus, transient ophthalmoplegia was a feature of the case, and the duration of the individual palsy seemed to bear some relation to the severity of the migrainous attack which preceded it. When first seen there was definite weakness of the right external rectus, with diplopia on looking to the extreme right, and there was also diplopia on looking upwards to the left. A few days later these signs had disappeared, and for over a month there was no diplopia or obvious squint. One of the worst attacks the patient had ever experienced then set in and diplopia appeared in the lower half of the visual field, particularly on looking downwards. On looking to the extreme left, the right eye would rotate in an anti-clockwise direction through about 20° and a temporary squint resulted, suggesting possibly some paresis of the fourth cranial nerve. As this occurred the nystagmus seemed to be aggravated for a few seconds and showed some rotatory movements. The patient remarked that his eyes were always wobbling when he looked to the left. While he was under observation, several transient palsies of the right external rectus occurred, but no involvement of the left eye was ever noticed.

Ophthalmoplegia is a well-known if infrequent event in migraine, but the other features of the case are, of course, rare. The attacks were accompanied by signs which would appear to be of cerebellar origin. I know of only two comparable cases in the literature. Oppenheim[5] described a single case which came under his observation:—

> "Each attack of migraine commenced with typical cerebellar symptoms. During the attack, standing and walking were very uncertain; the patient swayed like a drunken man, had severe vertigo, and a feeling as if his body or some portion of it were doubled up. The impairment of balance appeared and disappeared with each attack. The case might have been called '*hemicrania cerebellaris.*'"

The other case, recorded by Siebert,[6] showed a complete cerebellar syndrome with nystagmus in a single attack of migraine.

His patient, a woman of 47, had suffered for many years up to the menopause at the age of 44, from severe attacks of typical ordinary migraine, unaccompanied by any cerebellar symptoms. Then during a single day after three years of good health, a very severe isolated attack occurred. manifested by left-sided hemicrania. vertigo. ataxy on walking or standing but no incoördination on lying down. and nystagmus. The latter was very marked on looking to the right, and there was a tendency for the eyeballs to rotate on looking downwards and outwards. Three years later, when the case was reported. no evidence of organic disease had been discovered. there had been no further attack of migraine, no cerebellar symptoms, and the patient remained perfectly well.

The symptoms in the case now recorded were similar to, although much more persistent than, those of Siebert's patient. Cerebellar signs were present with each attack, and nystagmus was a specially noticeable feature. The proper assessment of the latter had to be considered very carefully in view of the fact that the patient had been a coal-miner for the preceding 14 years, working for the first four at the coal-face and the remaining ten as a haulier. As the result of very careful investigation, it was concluded that the nystagmus was not occupational. The classical features of miners' nystagmus include [7] delayed dark adaptation, movements of lights in the dark, headache and giddiness, blepharospasm and intolerance of light, together with nystagmus which is essentially rotatory. In the case under discussion the nystagmus was lateral, there was no blepharospasm or intolerance of light, and no failure in dark adaptation. In view of the importance and complexity of the case, it was thought wise to obtain the opinion of one with special knowledge of nystagmus in miners, and for this purpose Mr. Tudor Thomas, the ophthalmologist, was asked to examine the patient soon after he came under our care. He kindly gave the following report:—

> "The fundi are normal; no definite diplopia to-day. There is nystagmus on looking to either side. The nystagmus consists of quick fine jerks, and is a little more marked on looking to the left side. At times the movement becomes much more rapid—like a tremor. No typical oscillations of the eyes as in miners' nystagmus found; none on stooping, nor after shaking the head, &c., nor after stooping. No intolerance of light. No blepharospasm. Therefore the diagnosis of miners' nystagmus cannot be made."

When first seen the patient was put on bromide of potassium. His general condition improved, and he became less nervous and worried, trembling disappeared from his left leg, but the actual migraine was very little affected. He was then put on the classical prescription: sodii brom. grs. 10, liq. strychn. ♏4, liq. trinitrini ♏1, acid. hydrobrom. dil. ♏10, aq. ad. ½ fl. oz., t.d.s., and within a month definite improvement was noted. Headache became much less severe, nystagmus disappeared almost entirely, being demonstrable only on looking to the left and then very slight, diplopia became very infrequent, and teichopsia appeared on only one or two occasions. When after four months of this treatment he was seen again, he felt well and was anxious to resume work. He had had several attacks of migraine in this period, but they were much less severe and frequent than before the commencement of the treatment. Nine months after this he had been free from attacks except for two weeks following a period of a month without the medicine, nystagmus had disappeared, and there was no evidence of ocular paresis.

I have to thank the director of the medical unit, Prof. A. M. Kennedy, for much helpful discussion concerning this case.

MEDICAL SOCIETIES

ROYAL SOCIETY OF MEDICINE

SECTION OF OBSTETRICS AND GYNÆCOLOGY

At a meeting of this section on Oct. 21st, with Mr. J. P. Hedley in the chair, a discussion on the

Indications for and against Cæsarean Section

was opened by Dame Louise McIlroy. Cæsarean section, she said, was an artificial method of delivery much favoured by young surgeons and obstetricians. Pelvic contraction was the commonest indication for the operation, but in those cases where the degree of contraction was mild much could be learned from a trial labour. Many delivered themselves spontaneously. Trial labour had diminished the rate of Cæsarean sections, but it was not suitable for domestic practice. The dark horse of obstetrics was the case in which the pelvic brim was normal but the outlet contracted. By the time it had become apparent that spontaneous delivery could not occur it was too late to perform Cæsarean section. In asymmetrical pelvis trial labour was valuable; if the head entered the wide diameter of the pelvis normal delivery would occur, and if not, section could be performed. She also performed the operation in cases of breech with extended legs where attempts at version had failed, and in cases of persistent transverse presentation. Occipito-posterior presentations usually rotated spontaneously; but it was too late to perform section by the time it became apparent that rotation was not going to occur. In severe cases of ante-partum hæmorrhage where bleeding was concealed, Cæsarean section was possibly the only treatment, and certain cases of central placenta prævia were best treated in this way; shock to the mother from severe bleeding, and prematurity of the fœtus were contra-indications. Section could sometimes be performed for prolapse of the cord, but the operation must be carried out quickly if the child was to survive. Good results were obtained with patients suffering from heart disease by prolonged rest during pregnancy. and sedatives and anæsthesia during labour. Where labour was likely to be obstructed by a fibroid, Cæsarean section and myomectomy could be performed at term. She preferred to operate on ovarian cysts during pregnancy owing to danger of torsion of the pedicle. Eclampsia was only rarely an indication for section, but rigid cervix might require this treatment; amputation of the cervix sometimes left a scarred stump which failed to dilate at all. She asked whether the meeting considered a recent operation for prolapse a sufficient justification for performing Cæsarean section. She preferred to perform the operation after the onset of labour for three reasons: it was possible to be fairly certain that the child was not premature; if trial labour was employed spontaneous delivery might occur; the uterus contracted down and drained well afterwards. She had recently been using stovaine anæsthesia with success.

Mr. L. Carnac Rivett did not agree that the been acquired through residence in the endemic area. There was no doubt that, particularly under African conditions, adults were more frequently affected by the disease than children. But on the Demerara Dr. Giglioli found that children were three times as liable to blackwater fever as adults, and the morbidity was highest in the first decade of life, and was low after the twentieth year.

The recurrence of blackwater fever in certain families and houses was a striking characteristic of the epidemiology of the disease in this region. Of 63 cases, 22 originated from only nine families. Yet no local conditions had been traced which might render these particular houses more unhealthy or more malarious than a hundred others in the same neighbourhood; nor were the families attacked those who were more seriously harassed by chronic malaria. Dr. Giglioli held that the recognition of a house infection leading to blackwater fever implied that certain strains of malarial parasites transmitted at the same time or in succession to different subjects had the property of repeatedly producing blackwater syndromes. He argued that the disease must therefore be regarded as specifically related to such strains of plasmodium as could be considered to be biological varieties of the commonly known parasites, especially the estivo-autumnal species, which he referred to as hæmolytic strains. In most cases of blackwater fever no parasites were found and no definite precipitating factor could be determined; in others, unusual exertion, exposure to rain or sun, or alcoholic excess seemed related to the onset. The mixed settled population showed the least degree of immunity, but also the lowest mortality. The race immunity of negroes was remarkable, but if a negro acquired the disease the issue was more likely to be fatal. The action of quinine as a precipitating factor in a blackwater fever attack had been observed by all who had made a wide study of the disease; some, indeed, had described blackwater fever as a toxic syndrome specifically related to quinine. Nocht and Kikuth had found experimentally that quinine in vivo favoured hæmolysis and hæmoglobinuria.

Dr. Giglioli's studies had led him to the following conclusions: (1) That blackwater fever was the direct result of infection with special hæmolytic strains or biological varieties of the plasmodium. (2) That the epidemiology of blackwater fever was governed by the geographical and local distribution of such strains and the degree of immunity of the population. (3) That immunity to blackwater fever presented the same characteristics as immunity to malaria. (4) In individuals infected with hæmolytic strains the onset of hæmoglobinuria could be determined by special virulence of the infecting strain, by the absence of immunity and impairment of general non-specific resistance, by contingent factors tending to break down the immunity, and by quinine.

CLINICAL ASPECTS OF LONDON CASES

Dr. P. H. Manson-Bahr discussed the clinical aspects of some 20 cases of blackwater fever which had been under his care in London between 1919 and 1932; 16 of these were treated in the Hospital for Tropical Diseases. Only four of the cases occurred in women. In five the blackwater fever manifested itself while the patients were in bed being treated for subtertian malaria; it came "as a bolt from the blue," no previous blackwater stage having been ascertainable. In half the cases the attack began one to seven days after the arrival of the patients in this country; one, however, did not develop the disease until five and a half months after entering the country. The mortality-rate of this London series of cases was high, 40 per cent., the death-rate in the Central African colonies and dependencies being about 25 per cent. Two of the deaths were due to sequelæ, one to septicæmia, one to a boil on the nose while recovering from the blackwater fever, one to pneumonia, the other six to the hæmolysis of blackwater fever. The dramatic intensity of some of the cases was well illustrated by that of a lady who two days before attack arrived from Nigeria. She accompanied her husband to a theatre, and arriving back at her hotel at 11 P.M. felt well. Then she had a rigor, passed black water, was brought to hospital at 2 A.M. the next morning, and 12 hours later she was dead. Most of the cases came from West Africa, but some from Northern Rhodesia, Kenya, British Guiana, and Trinidad. The administration of quinine seemed to be definitely connected with the onset of blackwater fever. The disease was liable to occur in any patient infected with subtertian malaria after arrival in England, as long as the parasite remained active in his blood. Subtertian parasites were demonstrated in the blood of more than half of the London cases. A possible sequel of blackwater fever was cholelithiasis. As to treatment, Dr. Manson-Bahr recommended sodium bicarbonate intravenously with glucose, and blood transfusion.

Dr. N. Hamilton Fairley gave an account, jointly with Dr. R. J. Bromfield, of his laboratory studies made under a grant from the Colonial Office. They had demonstrated the presence of methæmoglobin and oxyhæmoglobin in the blood of subjects of blackwater fever, and said that the determination of the bilirubin and blood-urea was of value in prognosis. The cholesterol content of the blood was low, but when the kidneys were involved the quantity tended to rise. During the first 48 hours of the disease the blood pressure tended to be very low.

Dr. N. Fletcher showed by means of microphotographs the necrosis in the centre of the liver nodules associated with this disease. He had found that Asiatics afflicted with the disease had a low mortality, and he held that alcohol was useful in treatment.

Sir Samuel Christophers did not agree with the importance placed on hæmolytic strains of malaria parasites in the ætiology of blackwater fever. He was convinced that there was a time factor in the causation of blackwater fever, and that length of residence was important. The disease could be acquired after only three months' residence, but ordinarily it was not experienced under two years. In the bodies of blackwater fever patients some change seemed to have been produced by the parasites.

THE QUESTION OF HÆMOGLOBINÆMIA

Prof. Warrington Yorke considered it necessary to get to know more about the mechanism of this disease. Scarcely any worker on the subject had thoroughly investigated the question of hæmoglobinæmia; in this disease there was a small but definite degree of hæmoglobinuria. His own feeling was that the hæmolysis which occurred might be in the spleen and certain other organs which were rich in reticulum. Possibly some hæmoglobinæmia might be caused by proliferation of epithelium resulting from antecedent malaria. He did not think it reasonable to hope for improvement in treatment until more was known about the disease.

Dr. J. W. McNee said that in this disease we were concerned not with the activity of the reticulo-endothelial system, but rather with the great rapidity with which hæmoglobin appeared in the urine. He had found surprisingly little change in the liver and spleen in some of the London cases which he had investigated. Cases of blackwater fever bore a strong clinical resemblance to those seen during the war, in which transfusion was carried out with incompatible blood. These latter cases had perfringens infection at the same time.

Dr. J. H. COOK spoke of the difficulty of getting sufficient fluid into these patients because of their almost incessant vomiting; beer seemed to be kept down well by a number of them. He agreed with Dr. Manson-Bahr on the efficacy of intravenous injection of sodium bicarbonate (grs. 150 to the pint of water) supplemented by glucose. It was most important to prevent the onset of a chill in these patients.

Dr. H. S. STANNUS also agreed, but called attention to the treatment of blackwater fever by native beer in Africa. British cases should be given good ale.

Dr. TOM JAYS described his own attacks of blackwater fever, in the first of which, when he was alone and before he graduated, he took grs. 8 of calomel and grs. 100 of quinine a day for four days, then diminished the dose. He realised the great importance of conserving the heart's energy.

MEDICAL SOCIETY OF LONDON

AT the meeting on Oct. 24th, with the President, Sir JOHN BROADBENT, in the chair, a discussion was held on

Fractures of the Lower Jaw

Mr. W. WARWICK JAMES said changed conditions of traffic on the roads had led to greater frequency of fractures of the lower jaw and to more severe lesions. Jaw injuries had thus acquired greater significance in civil practice, but most of our knowledge was derived from experience in the war. His remarks were based on the results of four years' work at the Third London General Hospital. The underlying principles of treatment of those cases differed according to whether the fracture was of the body, involving the teeth sockets, or of the bone beyond the tooth-bearing area. The two groups differed considerably: the fracture was usually compound in the first, but very rarely in the second group, and these fractures of the bone beyond the tooth-bearing area bore a close resemblance to fractures of other bones. In an edentulous patient the conditions were altered, as the body of an edentulous jaw was not easily fractured. In some special conditions associated with the atrophied mandible of old age—malignant growth, extensive necrosis, and tabes—only a small force sufficed to cause fracture, generally of the molar region. Most of the fractures of the mandible, both in military and civil cases, occurred in young adults whose teeth were present. In children fracture of the mandible was not common; when it occurred a fall was usually the cause. Fracture of the front of the mouth was usually at or near the site of the blow; a fracture at the back of the mouth was usually the result of an indirect force. Displacement of a simple fracture in the front of the mouth was often a direct result of the injury, but displacement through muscular action was a more important factor, especially in multiple fractures.

The severity of fractures varied from the simple type, with little displacement, to those with much comminution, or with loss of both hard and soft tissue. Of the possible complications, dislocation of the condyle could easily be overlooked, while fracture of the maxilla and other injuries might add considerably to the difficulties of treatment. The commonest sites of fracture were in the region of the canine tooth, in the molar region, and through the neck of the condyle; it was unusual for the neck of the condyle to escape in multiple fractures.

Diagnosis.—Displacement was usually obvious, as was also impairment of function. Hæmorrhage from the torn muco-periosteum could be seen, and ecchymosis in the floor of the mouth was a valuable sign, while X rays gave conclusive evidence. Fracture of the condyle was associated with displacement of the mandible to the side of the fracture. The most distressing symptom associated with fractured mandible was the pain on movement of the fragments; and in these cases the mouth was always open, with the saliva dribbling out, the head being held very rigid. Movement of the tongue caused pain, and hence the patient swallowed as little as possible, and mouth and pharynx became fouled by debris. Early in the war when these cases remained untreated for days they became septic and offensive, many deaths occurring through inability to cough and the onset of septic pneumonia.

Treatment must consist of cleaning up the mouth and removing the fragments in such a manner as not to cause pain. In fractures involving the alveolar process, carrying teeth, there was a continuity of living tissue throughout the mandible; it was a grave error to regard the teeth as separate entities like nails in a board, and to ignore them and their sockets. Usually the line of fracture was oblique, passing between two teeth, and it was always compound. Necrosis seldom occurred if the fragments were at once brought into fairly accurate apposition. Should suppuration occur in the soft tissues, drainage at the most dependent part would mostly prevent the necrosis from becoming extensive. Mr. James considered that removal of a tooth was justified only if it interfered with the restoration of the fragments, or caused acute intractable pain. A frequent site of necrosis was the socket from which a tooth had been removed; often it was found that teeth which at first were condemned as hopeless became, if left in the mouth, of considerable functional value. A compound fracture of the jaw was less serious than a compound fracture of other bones, possibly because of the constant washing of the wound by saliva. In neglected cases notwithstanding necrosis might be extensive, especially if much pain was present, because pain led to great restriction of tongue movements. Even fragments of bone should be retained and restored to the positions they normally occupied unless actually detached; the periosteum might be intact, and new bone might be formed by the osteoblasts present. An external incision at an early stage might do much to prevent destruction of tissues. The treatment of fractures of the mandible consisted of two stages: restoration of the fragments to their normal position, and the maintenance of them there. Pain must be relieved, and the related soft parts stitched up to maintain the correct line of the mouth while avoiding tension. Suppuration called for drainage through an external incision. The displacement might be so slight that a four-tail bandage might suffice, but a carefully adjusted simple splint was better. A general anæsthetic should be given, and mostly the best result was obtained by wiring the teeth of the mandible to those of the maxilla, the muscles being then placed in a natural position of rest. A difficult complication was dislocation of the condyle, which might pass unrecognised. It was better to wait for radiograms before operating for this condition. Sometimes the rate of recovery was remarkable. Some patients were walking about in four or five days, and function was quite restored in eight weeks.

COMPLICATIONS

Sir **Harold Gillies** said that the chief complications which might occur in fractured mandible were: non-union, mal-union, delayed union, loss of bone substance, the obliteration of the buccal sulcus, and facial deformities. A surgeon called to a case of fractured mandible should at once call in a dental surgeon. Sir Harold much preferred a cap splint to wiring; the former was rigid, kept the whole jaw together, and could be fixed without an anæsthetic. When one tooth was present in the middle of a fragment, a cap splint would hold it in excellent position. In cases of mal-union of the mandible in which the fragments had not been properly controlled, the surgeon should be bold enough to undo the mal-union and reunite the fragments in good position, with or without a bone graft. In many cases of deformity resulting from mal-union of a fractured jaw the appearance could be improved by a buccal inlay, especially when a piece of bone was missing from the middle of the jaw. Delayed union and non-union were the same in the mandible as in other bones; but it was necessary to point out that teeth should not be left in necrosed bone, and that the interposition of a foreign body, such as a plate or a wire, must be condemned. He wished to correct any impression that teeth which were in the line of fracture should be left; to leave a tooth which showed signs of absorption round the roots in the line of fracture was an invitation for further necrosis and more delay in union, even for non-union. If a jaw was much comminuted and pieces of bone could only be controlled by utilising a tooth—i.e., in the line of fracture—it should only be utilised for long enough to keep the bones in position. He regarded surgical wiring of a mandible as bad practice, and plates equally so. All pieces of loose bone and fragments between the ends of the bones should be removed, as well as any tooth. Cases in which there had been much loss of bone substance, leaving a space of more than half an inch, should be treated ab initio with the idea that a bone graft was necessary.

Mr. **Percival Cole** said that for the 1300 cases of fractured mandible, which had come under his care during the war, 738 more or less major operations were performed. He supported Sir Harold Gillies's advocacy of the cap splint as against the wiring of teeth. The indiscriminate extraction of teeth in these cases could not be defended, but to conserve an obviously useless tooth was not wise.

Mr. **Zachary Cope** insisted on the need for collaboration between surgeon and dentist in these cases. Diagnosis was not always easy, and after a fracture had been sustained in civil life—usually after a boxing bout—it was apt to be overlooked by the subject, who probably attended at hospital later with a swelling. During the war he had dealt successfully with large gaps by bone grafts, some almost 3 in. across. He preferred catgut to wire.

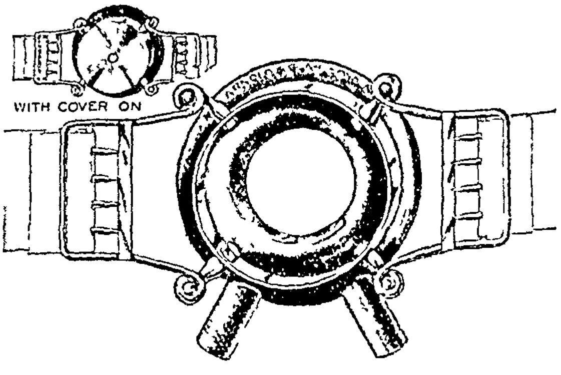
Mr. E. D. **Davis** said that in the early part of the war when a case of face or jaw injury came in, a huge dressing was applied and the patient was hurrie to the base. Later that routine was abandoned and the deformity was first reduced, the case cleane up as well as possible, and an attempt made t put the fragments into good apposition. Absolutel rigid fixation was not necessary, for union occurre even if there was slight movement between the fragments; the fixation, however, must be sufficien to prevent displacement deformity. A few of th cases died suddenly, and were found to have fractured base.

Mr. A. H. **McIndoe** said that in his experience fractures through the mental foramen were frequently associated with fractures through the opposite angle, and the latter could easily be missed. The four-tail bandage was an inefficient method of fixation. Sepsis alone did not cause delayed union, but sepsis in the presence of a foreign body was a very important factor. He agreed that the presence of roots of teeth in the fracture line was a potential source of chronic infection.

NEW INVENTIONS

SUPRAPUBIC DRAINAGE-BOX

Since introducing the sponge-rubber pad attachment for a Hamilton-Irvine suprapubic box, I have endeavoured to modify the apparatus so as to make it simpler and lighter. Mr. J. Alban Andrews has also been working with the same object in view, and I am indebted to him for some of the principles incorporated in the new apparatus. It consists of a round, instead of an oval, pad, which has the advantage of lying in better apposition on the patient, especially in thin subjects. The rubber tubes are fitted with "D"-shaped metal linings giving a better surface for contact, and are more comfortable than the round type. The rubber flange is made of thicker rubber, and is placed at right angles to its position in the original pad. On the outer and inner surfaces of the flange are two metal rings, half an inch in height, kept in position by four bolts passing through the rubber flange, and are prolonged externally to act as hooks for the buckles attached to an elastic webbing belt which keeps the apparatus in position (see illustration). These buckles are made of metal and are easily kept clean. I have found the new apparatus to be an improvement on the old one, both as regards being more comfortable for the patient and also for keeping him dry.



The apparatus is made by Messrs. Arnold and Sons (John Bell and Croyden), 50–52, Wigmore-street, London, W.

REVIEWS AND NOTICES OF BOOKS

Heart Disease

Principles of Diagnosis and Treatment. By CRIGHTON BRAMWELL, M.A., M.D., F.R.C.P., Assistant Physician to the Manchester Royal Infirmary; Consulting Physician for Women to the St. Mary's Hospitals, Manchester. London: Edward Arnold and Co. 1932. Pp. 244. 12*s.* 6*d.*

Dr. Crighton Bramwell has written a book which deals essentially with the cardiac problems met in the clinic, in the consulting room, and at the bedside. The work is based on a series of lectures forming part of a systematic course in medicine. These have been assembled into a consecutive story and although, as is stated in the preface, many aspects of the subject have not been included, all important general principles are considered. We are spared the orthodox introductory chapters on the anatomy and physiology of the cardiovascular system; the reader will be grateful that he does not have to wade through the formidable preliminary chapters which tradition seems to demand and which therefore can be found in most text-books on heart disease.

The book is divided into seven sections. The introduction deals with general principles, case-taking, imaginary heart disease, and the athlete's heart; the last-named chapter is of particular interest as it summarises the considerable literature which has grown up round this subject and includes the results of some personal observations made in 1928 on Olympic athletes at Amsterdam. The next section discusses heart failure; several pages are devoted to the chemistry of dyspnœa and cyanosis, an aspect of these conditions frequently neglected. Another important problem, whose discussion often falls between two stools, those being books on obstetrics and books on cardiology, is here fully discussed—viz., heart disease in pregnancy. Section III. on the cardiac mechanism will be welcomed by those who look on electrocardiography as a closed book; in the short space of 42 pages a clear description is given of rather more than the rudiments of what is well described as "the written language of the heart." Section IV. sets out the essentials of structural lesions. The few pages devoted to the technique of X ray examination of the heart are illustrated by some excellent radiograms. Section V. treats of cardiac intoxications, Section VI. of blood pressure and prognosis; this last includes an interesting section on anoxæmia and oxygen therapy, the different types of anoxæmia being considered from the aspect of whether or not they respond to the administration of oxygen. The subject matter throughout is illuminated with apt diagrams as well as with electrocardiographic records and radiograms. This book should be read by specialist and practitioner alike. That its size is small is due to the author's wise economy of words, and to his omission of unnecessary details.

It is a first-class work.

Medicine

Essentials for Practitioners and Students. By G. E. BEAUMONT, D.M., F.R.C.P., Physician with charge of Out-patients, Middlesex Hospital. London: J. and A. Churchill. 1932. Pp. 719. 21*s.*

Dr. G. E. Beaumont has had a wide experience of teaching, and has used it well in this new text-book of medicine. He has aimed at including only the essentials of medicine, having in mind the needs of students reading for examinations and of practitioners treating patients. He has succeeded in preparing a text-book which will satisfy both these groups, though the requirements differ widely. The effort which the writing of a text-book of medicine single-handed must involve has been repaid, for there is certainly a continuity and uniformity about this work that is often lacking in text-books by many authors. We have no hesitation in saying that Dr. Beaumont's book may well compare with most of its competitors, and at the remarkably low price of one guinea may be a successful rival.

The arrangement follows orthodox lines, and with the exception of psychology and dermatology the whole range of general medicine is included. The various diseases are dealt with concisely and for the most part adequately, and the space allotted to each condition is well-proportioned. The notes on treatment are sufficiently detailed to enable the practitioner to carry it out without reference to larger works; the repetition of phrases such as "any septic focus discovered should be adequately treated" may bore the student, but the practitioner should be grateful for a constant reminder of this important duty. The detailed diet sheets supplied should be of value; numerous prescriptions are to be found throughout the book. The index is usually good; we have submitted it to a searching test. But one criticism should be made—it is that medicine does not readily lend itself to a selection of essentials only. It happens too often in practice that the issue turns on an atypical symptom or an unusual sequela. Yet if we accept the principle that medicine can be presented at all adequately and in proper proportion when pruned of all extraneous matter we must admit that Dr. Beaumont has given here a good summary of medical knowledge and practice. The work is well printed and produced.

The Science and Practice of Surgery

Fourth edition. By W. H. C. ROMANIS, M.B., M.Ch. Cantab., F.R.C.S., F.R.S. Edin.; and P. H. MITCHINER, M.D., M.S. Lond., F.R.C.S. Vols. I. and II. London: J. and A. Churchill. Pp. 1762. 28*s.*

THIS book has established its place as a popular students' text-book. It has the great merit that it contains all that the undergraduate need know (and, indeed, much he need not concern himself with) in two reasonably sized volumes. This edition has been fully revised and many new illustrations have been added. Recent work on the spleen, sympathetic nervous system, rectum, parathyroids, varicose veins, burns, and blood transfusions have been incorporated.

The labour of writing a text-book on surgery is of such magnitude and in this case has been so fruitful that it is almost invidious to indicate places in which this book could be made even more useful. Speaking generally, the sections on minor surgery and on injuries to bones and joints are less satisfying than is the rest of the book. These sections give the impression that the authors have not observed very carefully the results of treatment, or they would not recommend such ineffective operations as they do for, say, ingrowing toe-nail and onychogryphosis. The difference between the prognosis after division of the dorsal and palmar tendons of the fingers is not mentioned, nor the essentially different methods of suture required. The description of the treatment of fracture of the shaft of the femur is inadequate, and the statement that the operative approach to the femur from the outer side is relatively avascular can hardly be the fruit of experience. The femur is nowadays approached from the front by a path to which the term avascular is certainly more appropriate. The method of applying strapping to the legs of a child in the Bryant suspension method, depicted in Fig. 227, would almost certainly lead to pressure sores from slipping if the weight were enough to raise the buttocks. When the authors say that in fracture of the lower end of the humerus the results are extremely good they are surely referring only to children. The statement is misleading as it stands; no emphasis is laid on the importance of early mobilisation of such fractures in adults. The only operation for recurrent dislocation of the shoulder mentioned is that of Clairmont which because of its limited success has been superseded by the much simpler procedures of Hey Groves and Henderson. Such useless and obsolete methods as removal of the cervical sympathetic for Graves's disease, epilepsy, or glaucoma might now be omitted from text-books of surgery. The authors are too optimistic in suggesting that femoral peri-arterial sympathectomy will produce considerable benefit in senile gangrene, or that due to thrombo-angeitis obliterans.

In Vol. II. we can find no mention of the use of the indwelling ureteric catheter for the pyelitis of pregnancy in which it often produces such dramatic results, nor is the ketogenic diet method of treatment described. In the section on the treatment of intrapelvic abscess the omission of any mention of the rectal or vaginal incision for drainage is curious; the student is recommended instead to give hot vaginal or rectal douches on the score that this treatment will promote spontaneous rupture. The view here taught that most cases of duodenal ulcer require surgical treatment would be regarded by the majority of surgeons as too extreme.

The general excellence of the work unfortunately throws up into relief these places, where the high standard is not maintained. But we call attention to them because the book has won such deserved popularity that a new edition will soon be called for, and adjustments in the places indicated would enhance the value of the book for teachers.

Minor Surgery of the Urinary Tract

By HERMON C. BUMPUS, Jnr., Ph.B., M.D., M.S. in Urology, F.A.C.S., Section on Urology, Mayo Clinic; Associate Professor of Urology, Mayo Foundation. London: W. B. Saunders Co., Ltd. 1932. Pp. 124. 15s.

THIS book is not, as its name might suggest, a treatise on the simpler operations that a surgeon may be called upon to perform on the urinary tract, such as circumcision and operations for varicocele. It is a book on operative cystoscopy by a well-known authority and therefore a work that will make its chief appeal to those who are expert in the use of the cystoscope. At the same time since trans-urethral methods are becoming more and more efficient and are occupying an increasingly important place in treatment, the general practitioner will find much in it that will be useful to him. As W. F. Braasch says in his short introduction, endoscopic surgery was given a tremendous impetus by the application to it, by E. Beer, of the high-frequency current. Used at first only in the treatment of vesical growths, it is now being employed for the removal of prostatic obstruction. The author's contribution to this development in prostatic surgery is well known to urologists and the book contains a good description of the Bumpus operation. However, the book deals with methods of treatment other than those associated with the use of high-frequency current. There are sections on stricture, lithotrity, the treatment of vesical ulcers by means of topical applications, the extraction of stones from the lower end of the ureter, and post-operative treatment. The fact that such modern methods as the use of a ketogenic diet in the treatment of sepsis have found a place in Dr. Bumpus's book is sufficient indication that the work is up to date.

The Principal Nervous Pathways

By A. T. RASMUSSEN, Ph.D., Professor of Neurology, University of Minnesota Medical School. London: Macmillan and Co., Ltd. 1932. Pp. 73. 12s. 6d.

TEACHERS of neurology fully recognise the importance of correlating structure and function in the nervous system, and of establishing a basis for clinical diagnosis in a sound knowledge of anatomical form. Unfortunately, however, the complexity of the system is such as often to render structural details uninteresting to the beginner, especially, perhaps, since the physiological purpose of many cell-fibre combinations is still unknown. To make the "dry bones live" is indeed a task for the instructor, and Prof. Rasmussen has sought to accomplish it by arranging anatomical data in a physiological way; he takes seriatim the main functional systems of the neuraxis and elucidates their component parts by a diagram in the first place, and a table of neuronic relationships in the second. His diagrams are of necessity laden with detail; yet, though printed in but one colour, they are remarkably clear; and if the student is not repelled by their elaborateness at his first glance he will assuredly learn much from their accuracy. Indeed, Prof. Rasmussen's charts and schemas really supply all the information about nervous pathways that can be desired by the student.

A Text-book of Neuro-anatomy

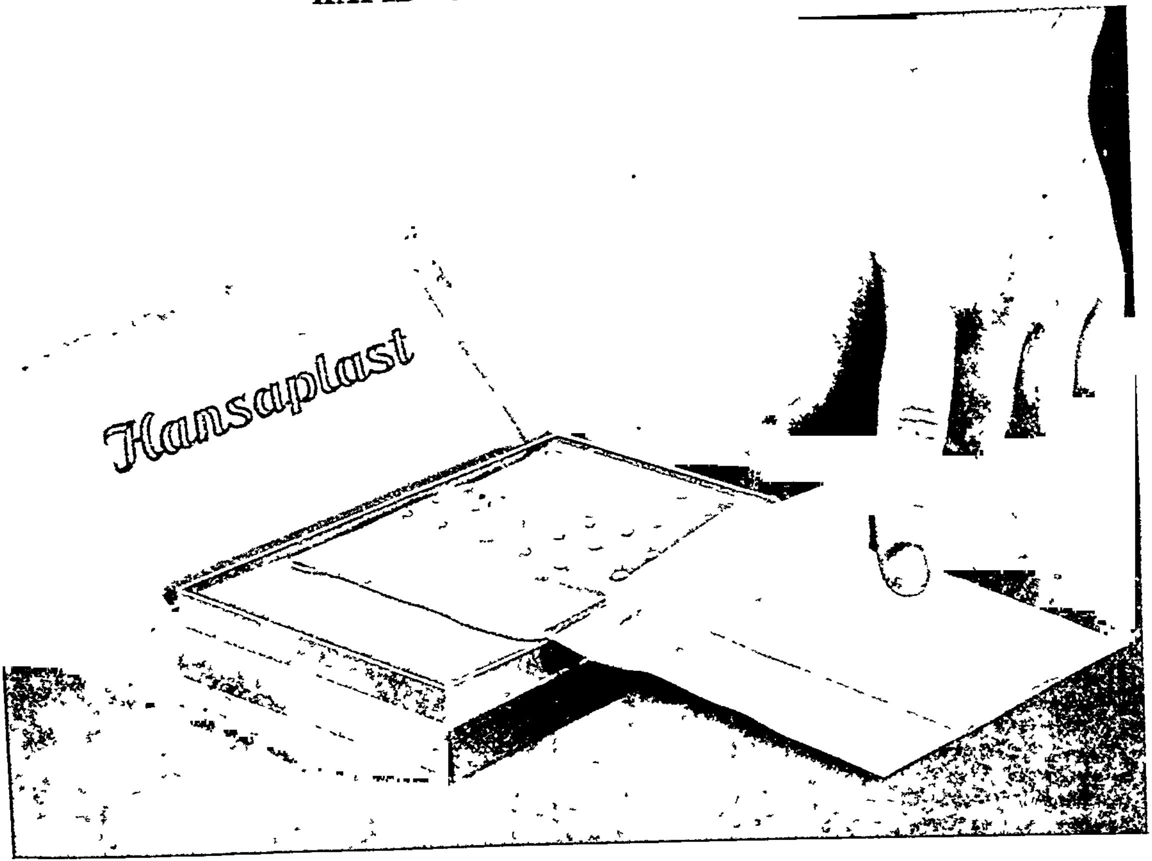
By ALBERT KUNTZ, M.D., Ph.D., Professor of Micro-anatomy in St. Louis University School of Medicine. Philadelphia: Lea and Febiger. 1932. Pp. 359. $5.50.

A NEW text-book of neuro-anatomy, written by Prof. Kuntz, should satisfy the requirements of the professing neurologist no less than of the student. The nervous system is dealt with from the standpoint of embryology, macro- and micro-anatomy, and in some degree also of physiology; apart from structural minutiæ, each of the main systems of the neuraxis is discussed in its functional relationships. Thus function is not only analysed, but it is also integrated; and as a consequence the reader obtains an excellent idea of the whole nervous system as a working and effective machine. There are nearly 200 microphotographs, drawings, and diagrams to illustrate the textual descriptions, and good bibliographical references at the close of each chapter for those who wish to prosecute their studies further. The book is of convenient size and clearly printed, and should serve a useful purpose.

When Seconds count and
Minutes may mean much

use **HANSAPLAST**

RAPID WOUND DRESSING



HANSAPLAST is a combination of Leukoplast, a gauze pad, and an effective antiseptic.

HANSAPLAST is a boon to the busy practitioner. One snip with the scissors provides you with a complete wound dressing.

HANSAPLAST once applied remains firmly in position on any part of the body, even on joints. Medical men agree that this modern wound application saves time, labour, and dressing material.

HANSAPLAST in the handy "Consulting Room" Pack should always form part of your equipment. The attractive metal cabinet contains HANSAPLAST in three different widths and can always be refilled.

child welfare clinics, tuberculosis, and simple health exhibitions. In Hungary, the fine State Institute of Hygiene at Budapest, founded in 1927, gives a nine months' course to 24 students and includes a nurses' school: nurses and health visitors undergo the same training in its early stages. Conditions are similar in Czechoslovakia, but in the districts of Bohemia there are far too many small hospitals and specialised clinics of various sorts—one district of 50,000 inhabitants in Prague having 11 different health organisations in charge of it. Thus concentration is necessary and it is perhaps unfortunate that hospitals and pharmacies are under the control of a legal department and not under the Ministry of Health.

Of all the Eastern European countries Yugoslavia, in the opinion of Prof. Prausnitz, is proceeding on the best plan and the most suitable and energetic lines, although of course poverty, racial and religious differences, and a low level of education mean that some time must elapse before the effects will have been felt all over the country. The mainspring of this work is Dr. Stampar, the director of the School of Hygiene at Zagreb, and so impressed were the League of Nations' authorities with the work done there that they asked Dr. Stampar and his assistant to be at the disposal of the Nanking government when they recently appealed to the League for help in reorganising the health services of China. The points which particularly excited Prof. Prausnitz's admiration were first, that the whole of the health services are unified under the Ministry of Health and Social Welfare; secondly, that each commune with a population of over 6000 has or will have a properly qualified M.O.H. and a "tertiary health centre"; thirdly, that the training in hygiene of the ordinary medical student is the finest in Europe, including as it does six months' hygiene, of which two months are spent in field work; fourthly, that architects and engineers taking the sanitary engineer's course study alongside the physicians taking the course for M.O.H.; and lastly, the splendid work done by the Peasants' University by which peasants come up for courses to Zagreb and return to their villages to become leaders of health education.

It is in Russia, as might be expected, that the most striking and original departures have been made from the generally accepted schemes of medical education. The problem before the authorities is how to produce a large number of adequately trained doctors as quickly as possible and an attempt is being made to shorten the curriculum by specialisation from the very beginning of the course. The scheme is as follows:—

1. Medical prophylactic faculty: physicians, surgeons, and dentists.
2. Sanitary prophylactic faculty: M.O.H., communal M.O.H., epidemiologists, nutritional medical officers, and factory medical officers.
3. Maternity and child welfare: women, infants, and children.
4. Physical culture.

Before beginning his studies the student has to choose or has chosen for him the faculty which he will enter, the proportionate numbers allotted to each faculty being 24, 13, 15, and 2. A choice which turns out to be unsuitable can be remedied by a course at an institute for post-graduate training. Students are of two different classes; one class enter after they have completed their ten years' education in the ordinary way, the others, in approximately equal numbers, are drawn direct from the ranks of the working-classes and are often, of course, somewhat older. Instruction is far more practical than with Western European nations and the second class of student do not appear to be inferior to the others. Students are housed, fed, and paid by the State and live in "messes" of half a dozen or so, great use being made of the spirit of competition between different groups. It should be noted that some 60–70 per cent. of the students are women. The original plan of 1930 was superseded last year by the plan outlined above; so that it is far too early to criticise any results, but it is certain that all who are interested in the teaching of preventive medicine will watch the developments in the U.S.S.R. with the greatest attention.

THE DRINKER RESPIRATOR IN ASPHYXIA NEONATORUM

THE construction of the Drinker respirator has already been described in our columns,[1] and its value in the treatment of respiratory failure in anterior poliomyelitis has been emphasised.[2] It will be recalled that the apparatus is designed to provide artificial respiration over a long period with a minimum of trauma to the respiratory system; the patient's body is placed within a closed tank, his head passing to the exterior through a closely fitting rubber collar, and by means of electrically driven blowers a negative pressure is produced within the tank, alternating with a return to atmospheric pressure. The negative pressure causes the patient's chest to expand and air to be inhaled, whilst on return to atmospheric pressure the recoil of the thorax and elasticity of the lungs result in expiration. The rate and depth of respiration can be varied at will. The method is of proved value in the treatment of carbon monoxide poisoning and in the respiratory failure in anterior poliomyelitis, and is extensively used in America; in this country an apparatus is available on application to Sir Robert Davis (187, Westminster Bridge-road, London, S.E.1).

Besides the full-size model, a much smaller apparatus of similar design has been constructed for infants. As indicated in the illustrations already published,[1] this can be heated if necessary and the child can be closely observed in it. Dr. D. P. MURPHY and Dr. J. V. SESSUMS[3] have now reported the results of treatment of 66 cases of asphyxia neonatorum with the Drinker respirator in the University of Pennsylvania and Philadelphia Lying-in Hospitals. The cases selected were those showing entire absence of respiratory activity (owing to which a number of stillborn infants were unintentionally treated) or very feeble and infrequent respirations; all treatments were started within ten minutes of birth. From earlier observations Murphy and Sessums had found that in moderate degrees of asphyxia neonatorum alternation of negative and atmospheric pressures was sufficient to bring about adequate ventilation of the lungs: but in cases of severe asphyxia they conclude from measurement of the air moving to and from the lungs that alternation of negative and positive pressure is an advantage. They therefore recommend the use of both positive and negative pressures (preferably equal) in all such cases, whether the asphyxia is severe or not. Of the 66 infants treated, 15 failed to breathe at any time, 5 breathed before but not after treatment, and of the 46 that breathed at least once during treatment, 39 developed finally an adequate degree of respiratory activity. Thirty of these last survived and nine died in hospital. A detailed analysis is given of the causes of the asphyxia as far as they could be determined on clinical and pathological grounds, and it is found that narcosis or injury (either due to breech or forceps delivery) accounted for the condition in nearly 64 per cent. of the series. Of the 36 infants which died, 19 (14 autopsies) suffered from cerebral injury; 15 were stillborn.

[1] THE LANCET, 1931, i., 1187; also 1150.
[2] Ibid., 1932, i., 1211.
[3] Surg., Gyn., and Obst., October, 1932, p. 432.

It is concluded from the observations made that narcosis is the most common single cause of asphyxia neonatorum, and that if possible maternal narcotics should be given not later than four to five hours before the expected time of delivery. Breech deliveries, on the other hand, were followed by the greatest number of deaths. It was found in general that treatment with the respirator was of greatest value in infants suffering from excessive narcosis (since these showed the lowest mortality), and in premature infants which seemed to survive their initial asphyxia although they did not always live long after birth. As far as the effect of artificial respiration on cardiac action could be determined, it appeared to be decidedly beneficial. In no case was there any evidence of injury having been caused by use of the respirator.

THE ÆTIOLOGY OF TRACHOMA

The letter from our Budapest correspondent in our issue of Oct. 15th reminds us that the long drawn out campaign against trachoma in Eastern Europe shows few signs of drawing to a close. In some parts of Hungary the disease has long been endemic, but largely owing to the efforts of Prof. E. de Grosz the proportion of trachoma among eye cases presenting themselves at the university clinic in Budapest fell from 7·2 per cent. in 1891 to 2 per cent. in 1910. During the years 1914–1918 the segregation of trachoma in special regiments was successful in limiting infection, but when peace was restored the disbanded men carried the disease to areas hitherto immune, and in 1926 among the 8½ million inhabitants of Hungary 10,000 cases of trachoma were brought to light. In western Canada the position is equally unsatisfactory. Prof. G. M. Byers, of McGill, warned[1] the last meeting of the Canadian Medical Association of the gravity of the situation in Saskatchewan and especially Manitoba where trachoma was introduced by the Mennonites who came from Russia to settle in the Red River Valley in the early seventies. The eastern provinces into which trachoma was introduced by settlers returning from Napoleon's Egyptian campaign are now practically free of the disease as the result of favourable climate, better social conditions, and the work of oculists such as Buller and Desjardins, assisted by the absolute exclusion since 1927 of trachomatous immigrants. The disease does not now exist in Quebec city and for five years it has been found impossible to demonstrate a case of acute trachoma at McGill University. In the western provinces cases are now being rounded up and brought to the clinics by public health nurses. The disease however remains prevalent among the Indians of British Columbia and the prairie provinces: it is believed that 10,000 or more of the estimated Indian population of 110,000 have suffered from the disease.

Progress still awaits exact knowledge of ætiology. One of the last communications of the Japanese pathologist Noguchi, from the Rockefeller Institute where he spent the closing years of his life, was the announcement of the discovery of a bacillus which he believed to be the causative agent of the disease. Five years have passed and of the many pathologists who have repeated Noguchi's experiments in many countries only a very few have been able to produce evidence purporting to confirm his results. Among these few, however, were some of the Rockefeller workers, and it is worth remembering that the late Ernst Fuchs, visiting America in 1930 after examining some of the monkeys which had been inoculated with the *Bacterium granulosis*, gave it as his opinion that they were suffering from undoubted trachoma. On the other hand, Dr. Rowland P. Wilson, director of the Giza laboratories, has pointed out[2] that the form of granular folliculitis produced in monkeys by various experimenters with *B. granulosis* is indistinguishable from that which can be induced by simple measures or the form which occurs spontaneously. Most decisive is his observation that pannus has never been observed. An extended investigation of the bacteriological aspects of trachoma has been carried on for some years by Dr. Ida A. Bengtson for the U.S. public health service.[3] Attempts to isolate *B. granulosis* were made in 73 cases of human trachoma, principally from the State of Missouri, between the time when cultures of the organism were made available by the Rockefeller Institute in 1929 and July, 1931, but the results were negative in all cases. With regard to the experimental production of granular lesions in monkeys and apes by means of inoculation with cultures of the organism, the results of various workers (there are records of some 300 of such experiments) are contradictory, but in no instance apparently has it been proved that the disease is identical with trachoma in man.

---

[2] Brit. Jour. Ophth., 1931, xv., 433.

[3] Public Health Reports, Washington, Sept. 16th.

What has been produced by some of these experiments is a granular progressive type of lesion transmissible from animal to animal; in the tests carried out by Dr. BENGTSON herself the transmission was effected by the simple method of swabbing the diseased conjunctiva and conveying the infective material to the healthy conjunctiva of another animal. There have been a number of experiments in the transmission of trachoma from man directly to monkeys and apes, but none has yielded any striking result. A few observations are recorded on blind human subjects or on persons who volunteered to have the conjunctiva inoculated with *B. granulosis*; but although positive results have been claimed, Dr. BENGTSON considers that the results have been almost as inconclusive as in the test monkeys. To sum up, while it must be granted that the *B. granulosis* is capable of producing a granular condition of the conjunctiva in rhesus monkeys, and that this condition is transmissible from animal to animal, more efficient methods for demonstrating the organism are greatly to be desired. In America it has been demonstrated in cases of human trachoma occurring in certain districts, and this fact merits consideration, but it cannot be the efficient cause of the disease in all cases.

ANNOTATIONS

PRESENT-DAY RADIOLOGY

THE development of radiology to occupy a most important place in medicine was surveyed by Dr. Russell J. Reynolds in his presidential address to the Section of Radiology of the Royal Society of Medicine, on Oct. 21st. He dealt first with the improvements being made in the construction of tubes, apparatus, and devices for the protection of patient and worker, and in the technical methods used especially in the study of moving parts of the body. His review of the growing use of radio-opaque substances showed that hardly a cavity in the body has resisted one or other of the ingenious processes designed to make its outline visible without more than trivial inconvenience to the patient. The president pointed out that the first worker to use a radio-opaque substance in the body had been Strauss, who in 1896 had caused his patient to swallow capsules filled with barium subnitrate, and had subsequently traced them on the fluorescent screen. Lipiodol, first used in 1921, had proved of the greatest assistance in the investigation of spinal tumours, the condition of the lungs and pleural cavities, the accessory air sinuses, the genital organs, and the lacrymal sac. It should not, however, be used in cases of extreme iodine intolerance, active tuberculous disease with pyrexia, and poor health. Pyelography was, he said, another valuable aid to diagnosis; the intravenous route dated from 1923, when observers at the Mayo Clinic had found that the urinary tract could be outlined by the injection of sodium iodide. The "dye" technique for outlining the gall-bladder had been discovered in 1924. The intravenous technique for cholecystography was not often used nowadays, as oral administration gave very good results and was free from danger. The field of embryology and obstetrics had been rather more slowly invaded by radiology than other fields, but valuable information could now be obtained on the condition, age, position, and size of the fœtus, and there seemed to be no danger in a short diagnostic exposure. In 1921 D. A. Horner and in 1922 A. B. Spaulding had shown that fœtal death could be demonstrated by overlapping of the skull bones. Many methods of radio-pelvimetry had been devised, notably the simple and accurate one introduced by L. Rowden, and the condition and position of the uterus and Fallopian tubes could be ascertained with the aid of lipiodol.

Ventriculography and encephalography were invaluable for studying intracranial lesions. Recently Dr. Laruelle, at the Central Neurological Clinic in Brussels, had obtained excellent results by injecting such small quantities of air as 3 or 5 c.cm. without withdrawing any cerebro-spinal fluid, the patient suffering no inconvenience. Sialography was another recent technique. Thorotrast was now used to obtain shadows of the liver and spleen, but great care was needed. Arteriography was a valuable means of diagnosing cerebral tumours.

Despite the heavy criticism which had been levelled against the X ray as a therapeutic agent, it held a very strong position to-day. Shortly after the application of the rays for diagnosis a dermatitis with epilation had been noticed. This untoward incident had been the genesis of radiotherapy. G. B. Batten in London had treated one of the first cases of ringworm of the scalp, and cases of lupus, sycosis, and eczema had been treated very early. The effect of the rays on tissues was a destructive one, and diseased tissues were more susceptible to the effect than healthy ones. The tendency to-day is to use still higher voltages, and the rays thus produced were far more penetrating than anything previously used, so that deeper lesions could be attacked. Various methods of measuring dosage had been used in the past, but the common unit to-day was the "r." It was now possible to determine more or less accurately the exact dose given to a tumour at a certain depth under specified conditions. The tendency to-day was to fractionate the dose more and more, so that the patient's vitality was kept at a maximum, enabling him to put up the best possible fight against disease. Fortunately, as time went on, less was heard of the harmful effects of X rays. The acute burn was almost extinct, chronic burns were rare, and blood changes from short wave-length rays were few, because radiologists were realising more and more the necessity of taking reasonable precautions. In the president's view, the position of radium therapy to-day commanded great respect. Those who had used radium for some years had no doubts of its value. General experience tended to show that needles were to be preferred to seeds. During the last year or so efforts had been made to put radium therapy on a much more scientific basis. As time went on its interstitial use would more and more give place to surface technique.

A TEST FOR BLOOD

THE benzidine test for the presence of blood in urine or fæces depends upon the peroxidase action of hæmatin. It is usually performed with hydrogen peroxide or ozonic ether; the former has the disadvantage that it is readily subject to decomposition, the latter that it is expensive. Mr. John Ingham,[1] of the medical unit of the Welsh National School of Medicine, has lately drawn attention to the value of Hyperol, a compound of hydrogen peroxide and urea, in the performance of the test. Hyperol is said to be cheap and absolutely stable at ordinary temperatures. In the performance of the test on urine a few crystals of benzidine, two drops of acetic acid, a drop of urine, and a pinch of hyperol are brought together on a white plate; the presence of blood is shown by the development of the usual blue colour. In the case of fæces a watery emulsion is made and heated to over 60° C., two or three drops of acetic acid are added and the mixture is cooled. The test is performed as for urine, with a drop of the watery extract. If a more delicate test is desired the acidified watery emulsion may be extracted with ether and the test performed on the separated ethereal extract. An even higher degree of delicacy may be obtained by evaporating the ethereal extract, redissolving in water, and applying the test. Ingham claims that by this means blood may be detected in a 1 in 3,000,000 dilution; but the value of such delicacy for a clinical test is of course open to doubt.

BATHS AT MARGATE

THE Isle of Thanet claims to have the purest and most invigorating air in the world together with the maximum of sunshine and the lowest rainfall in the country. The town council of Margate has added to these natural attractions an installation of medical baths, under the supervision of Dr. G. L. Brocklehurst, the medical officer of health, where consulting rooms are available for medical men and their patients, with a trained staff to carry out the prescribed treatment. The latest addition to this is a series of Sandor foam baths for use in disorders of the cardiovascular system where other methods of applying hot air and water are undesirable. In opening this new Physical Treatment Institute on Saturday last, Sir StClair Thomson recalled that it was Dr. Lettsom, a past president of the Medical Society of London, who in 1791 founded the Royal Sea-bathing Infirmary at Margate, and was thus the pioneer in the treatment of surgical tuberculosis by climate and open air. Margate, he said, fulfilled the conditions laid down by Hippocrates in his "Airs, Places, and Waters." With its high record of sunshine, low rainfall, and freedom from mists and fogs, Margate offered special attractions for feeble and ill-developed children, for convalescence after operation or illness, for catarrh of the air-passages, and for the ever increasing number of neurasthenics. He had little doubt, Sir StClair remarked, that when Hamlet was sent to visit England, his uncle Claudius had Margate in his mind when he said:

> "Haply the seas and countries different
> With variable objects shall expel
> This something settled matter in his heart."

The "waters" of Margate provided what was perhaps the finest and safest sea-bathing in Europe, and the baths could be enjoyed all the year round. Medicine was sometimes jeered at as an uncertain science because it was always changing, but it was just because it was changing that it was progressive, and since the days of Lettsom the armamentarium of the physician had been enriched by physical methods such as massage, movements, heat and cold, wet packs, a wealth of applications of electricity, and hydrotherapy in all its forms. In the success of every remedy there was, as they all knew, a large physical element, and those healing measures would have more chance of cure in the bracing air of a town like Margate, with the interests, sports, and distractions it could supply. Every well-ordered centre of convalescence has to make good the deficiences of a northern climate, and Margate, having borne a hand for a century and a half in the treatment of tuberculous children, may now play its part in bringing home to the public the efficacy of physical treatment, given with the same accuracy and skill as drugs or operations.

IS THERE A MOTOR FACTOR IN DEXTERITY?

A REPORT[1] just published by the Industrial Health Research Board tells of a search for the existence of a motor factor—in contradistinction to a mental or intelligence factor—in the make-up of the human machine. All activities fall into the province of one or other factors. Thus the solution of a mathematical problem belongs to the mental factor, while an activity such as walking, that usually proceeds without conscious control, clearly belongs to the motor factor. Estimates of intelligence can now be made with some confidence; but estimates of manual abilities have, in the past, proved so unsatisfactory as to give rise to a doubt concerning the existence of a motor factor. Yet if such a factor does exist, and can be measured, information regarding it would be invaluable in vocational guidance. The author sought earnestly, using certain familiar laboratory tests devised for estimating manual dexterity, and he detected indications of a common motor element in all the tests in question. Then he pursued this clue by extending his search into dexterity displayed at definite industrial operations of accepted utility, such as wrapping shaving soap or toffee, packing needles, and making flies for angling. Evidence was forthcoming of the existence of a motor factor common to each test, and of its being central in origin rather than localised in the end organs. While the precise nature of the factor remains obscure, it seems to be largely manipulative, dependent perhaps on factors, such as hand and eye coördination, and speed of movement. One side point of interest emerged in the inquiry—viz., that in many dexterous performances speed is promoted rather than decreased by regard to accuracy.

BERTRAM WINDLE

THERE are men of whom it is difficult to say what they did that was great, while feeling that they filled rightly a great place in affairs. To this category belongs Sir Bertram Windle, whose affectionate biography has just appeared.[2] He was a distinguished biologist, wrote and examined much on anatomy, and the doors of the Royal Society were opened to him early in his career. He was a constructive authority on education, and held university professorships in England, Ireland, and Canada, impressing his own individuality on the first two in particular, and advancing generally measures of progress. At Birmingham, where he was professor of anatomy and anthropology for 20 years, he was one of the prominent advocates of the institution of the University. At Cork he did much energetic work as principal of University College, and here his devotion alike to scientific research and Roman Catholic doctrine furnished him with intimate material for semi-theological argument and for the writing of that valuable book in defence of revelation, "The Church and Science." He sat for considerable periods on the General Medical Council, representing first the University of Birmingham and later the National University of Ireland, and he was the author, outside scientific papers, of many books of history and archæological associations with the countryside. A many-sided personality, his interests were perhaps too diffused to ensure any one of them being pursued to the point at which he aimed, and this can be surmised from the long record of his life so piously set out by his biographer.

THE STORY OF HEALTH INSURANCE

While maintaining a pleasant format and arrangement Dr. McCleary has managed to encompass within his little book[1] a fairly comprehensive review of national health insurance, regarded especially as a measure of public health. The practitioner, whether on the panel or not, should find a place for it on his bookshelves, even in these hard times. The book is not intended in any sense as a handbook for the insurance doctor; his needs in this respect are well provided for elsewhere. The man who is interested in his job, however, will be glad to read how health insurance has come about and how it works elsewhere; with some general reflections on the good points and the bad of the British system. In Europe, we read, a system of national health insurance on a compulsory basis now finds its place in nearly every country. France is one of the latest to adopt a system which on its medical side follows the essential provisions of the British plan, though with a closer approximation to the conditions of private practice. It is interesting to be reminded that the foreshadowing of a compulsory scheme in this country in Mr. Lloyd George's budget of 1909, based on a Bismarckian precedent, actually went for some weeks unnoticed in the medical press, except for the remarkable letter[2] in our own columns by the late Dr. J. A. Keay of Greenwich. Those who would like to read again of the events of 1911—how the Statute left the House of Commons a very different measure from that which was introduced; how the British Medical Association carried in substance their six cardinal points (the panel system, we are reminded, did not owe its origin to the Government but to the Association); and how, as they were humorously told by the *Westminster Gazette*, the Association did not know when it had won—will find the story well told in these pages. Dr. McCleary tells us that insurance, of a kind, commenced with the social guilds in the middle ages and, passing through other stages, including the wonderful provision made by the friendly societies in this country, ended in the compulsory scheme in which those societies themselves played such an active part. Many a harassed panel doctor will read with a sigh of the declaration required from its members by the eighteenth century Loyal Unity Union Society of Lancashire:—

> "I do declare that I will not complain of sickness so as to be troublesome to the box [the old name for the sickness funds] without just cause . . . and as soon as it shall please God to give me health and strength I will immediately declare off the box."

The chapters on the social value of health insurance and its future development will be read with special interest. The medical service will, in the author's opinion, inevitably tend to become separated from the cash benefits, and yet, great as are the deficiencies of the service and great as is the need for its coordination with the health work of local authorities, the medical service remained untouched by the insurance legislation which followed the Royal Commission of 1926 and by the Local Government Act of 1929. Two other quotations in Dr. McCleary's book are of interest. Of the medical service he writes: "The most effective influence that keeps the insurance practitioner up to the mark is his own professional conscience." And of the insured person: "Deliberate imposture is not common. But it is not difficult for a man with a slight ailment to persuade himself that his repugnance to sustained exertion is evidence of incapacity for work."

THE ECONOMICS OF TUBERCULOSIS

IN a presidential address to the Tuberculosis Association, on Oct. 21st, Dr. Jane Walker began by remarking that if infection is to be the basis of any attempt to control tuberculosis it was doomed to failure. The control was largely psychological; anything that lowered vitality, whether it was anxiety, softness of living, poorness of living, bad housing, alcoholism, or what not, tended to make an easy victim to the disease. Economically considered, perhaps the most important difference between tuberculosis and most other infectious diseases was the length of time it lasted, and the great variety of its manifestations. No accurate figures were available about the incidence of tuberculosis in England and Wales; the incidence of the disease must be measured by its death-rate, which was going down. In England and Wales in 1901 the deaths from tuberculosis numbered 58,930; in 1911, when the first National Health Insurance Act was passed, they numbered 53,120—a drop of 5810 before the great concerted effort began. Public opinion, said Dr. Walker, was not aroused until the worst was over. The decline was obviously not entirely due to the anti-tuberculosis measures taken; it might be due, at least in part, to what had been called "the subsidence of a prolonged epidemic wave," as in the analogous cases of small-pox and scarlet fever. But we were, she added, constantly being pulled up and brought face to face with some new factor in this disease, such as the observation that the mortality among young women had not gone down at the same rate as that among young men. It had, in fact, even risen to some extent. The same thing occurred during the war, and there was, she thought, a clear connexion between the two observations. At one time tuberculosis was regarded as a home disease, and it was thought that if people got out more and perhaps earned more money to put into food and other household amenities, tuberculosis would go down. The increased mortality-rate among young women did not bear this out. Many of the occupations held by women at the present time involved more arduous exertion than had been customary for them, and it was true, as Dr. Burton Fanning had said, "there are few causes more powerful to determine the outbreak of pulmonary tuberculosis than physical over-exertion. In at least 10 per cent. of my patients the disease seemed directly attributable to their having overdone themselves. . . . It is important to recognise that although exercise be taken in the open air, it is conducive to the development of consumption if it entails exhaustion or fatigue." It was a fact, however, that whatever the causes of the decline might be the general tuberculosis mortality was steadily going down. What the Association had to consider was how could the decline be speeded up. The tragic result of tuberculosis was the patient's gradual loss of working efficiency, so that he fell steadily in the social scale because less and less money was coming in. These cases, steadily getting worse and so less efficient, were the real crux of the problem; they were not the cases with which the sanatorium should be expected to deal. For such patients really cheap accommodation should be provided without the paraphernalia deemed necessary for cases likely on the one hand to die quite shortly, or on the other to recover and take their place in the world as useful citizens. Such institutions would need few nurses and no resident medical officer; the food might be of the same nature as that to which the patients were accustomed at home; and, since the buildings need not be designed on the lines of a modern sanatorium, it might be possible to take over for this purpose some of the mansions which their owners were now unable to keep up. The ordinary work of such a house could be undertaken by the patients. Each of these institutions should be for one sex only, the supervision being easier and the place less costly to run. Household duties would not occupy all their time, and some definite occupation should be carried on whereby the inmates might earn a little money varying with their proficiency. While a plan of this kind would suffice for single men and women, for the families there was nothing better than removal to a village settlement. Success in dealing with tuberculosis did not lie in any one direction.

VIRUSES OF THE POCK DISEASES

Discussing vaccination and small-pox in his presidential address to the Pathological Society of Manchester on Oct. 12th, Prof. H. B. Maitland spoke of the possibility of modifying the viruses of the pock diseases by passage through various animal species. Not only could changes in pathogenicity and tissue affinities be effected, but it had been shown recently that the viruses may be altered to some extent antigenically. There was still, however, some essential antigenic correspondence between variola and vaccinia, since vaccination protected against small-pox. The virus of vaccinia was now held to be represented by the Paschen bodies. The nature of immunity to vaccinia was on broad lines comparable to antibacterial immunity. Antibodies had been demonstrated by the reactions of agglutination, precipitation, and complement fixation. They could also be demonstrated by the in-vitro neutralisation test. It appeared probable that the virus was sensitised by contact with immune serum. It was not rapidly destroyed, and virus could be recovered for a time from such a mixture. There was evidence that phagocytosis might be an important factor in immunity. Prof. Maitland made the interesting suggestion that the production and study of culture-virus had now reached a stage in laboratory investigations when serious consideration should be given to the possibilities of utilising it on a large scale for human prophylaxis. The lesions produced by culture-virus were like those caused by calf-lymph, and an advantage of using culture-virus as a substitute for calf-lymph in performing vaccination on children would be its freedom from bacteria. Prof. Maitland noted that the establishment of immunity to vaccinia without the production of lesions had now been achieved in animals. Killed virus was a weak immunising agent, but its efficiency might depend on the method used for killing it. Further exploration might reveal that the best conditions for preparing a killed prophylactic had not been attained. Mixtures of virus and immune serum could induce a considerable degree of resistance in rabbits and monkeys, and might in man be capable of providing a serviceable immunity. In such mixtures the virus was not dead, but its admixture with serum prevented the occurrence of lesions. There was some evidence to suggest that resistance to vaccination after recovery from infection might depend upon the persistence of living virus in the tissues, but this point had not been fully worked out. Whatever future work may bring, Prof. Maitland made it clear that at the present time the fact that living virus is much more effective than dead virus in establishing immunity is indisputable.

CHAUCER AND MEDIÆVAL MEDICINE

At the ninth international congress of the history of medicine held at Bucharest from Sept. 10th to 18th, under the presidency of Dr. Victor Gomoiu, Dr. J. D. Rolleston, the representative of the British Government and delegate of the Royal Society of Medicine, presented a paper on Chaucer and Mediæval Medicine. With the object of illustrating contemporary medicine by quotations from belletristic literature, as he had done in several previous essays, Dr. Rolleston had collected the various medical allusions in Chaucer's works under the headings of the medical profession in Chaucer's time, contemporary medical doctrines, various diseases and their treatment, and miscellaneous topics. The doctor of physic portrayed in the Prologue to the Canterbury Tales stands for the properly qualified practitioner of the time who had been brought up on the works of Hippocrates, Galen, Rhazes, Avicenna, and other medical authorities, and was probably modelled on John of Gaddesden. The contemporary medical doctrines of the four elements—earth, air, fire, and water—of which man was thought to be composed, of the four humours—hot, cold, moist, and dry—and of the four complexions or temperaments—the sanguine, the choleric, the phlegmatic, and the melancholic—are illustrated in several passages in the Canterbury Tales and elsewhere in Chaucer, the somnour in particular being an excellent example of the sanguine type. The same pilgrim was also the subject of an intractable acne rosacea which was doubtless not unconnected with his alcoholic habits. After quoting the passages relating to the plague, leprosy, and malaria, which were the most important diseases prevalent in Chaucer's time, Dr. Rolleston maintained that in view of the frank presentation of the physical side of sexual life in Chaucer's works, the absence of any allusion to syphilis, which was so frequently mentioned in Shakespeare two centuries later, was extremely valuable evidence against the existence of the disease in the age of Chaucer. Had syphilis been prevalent then Chaucer would most probably have represented one or more of the free-living pilgrims as suffering therefrom, and the section in the Parson's Tale relating to "leccherie" would have included a warning of the dangers awaiting the sinner. As regards treatment, the principal remedies mentioned by Chaucer were such drugs as emetics, purgatives, aphrodisiacs, and the panacea theriaca which had been handed down from classical antiquity, and in the middle ages was called triacle, ointments, herbs, and charms. The miscellaneous topics of medical interest in Chaucer include the passages in the Parson's Tale dealing with the overlying of children, criminal abortion, and infanticide, the existence of privies, and the success of quack veterinary practice, so amusingly described in the Prologue to the Pardoner's Tale.

THE OFFICE INTERNATIONAL D'HYGIÈNE PUBLIQUE

Sir George Seaton Buchanan, senior medical officer of the Ministry of Health and delegate for the United Kingdom, has been appointed President of the Permanent Committee of the *Office International d'Hygiène Publique*, in succession to the late Mr. Otto Velghe, secretary-general of the Ministère de l'Intérieur et de l'Hygiène at Brussels. Mr. Velghe had held that office continuously from 1919 until his death at Geneva which occurred suddenly whilst he was attending the session of the Health Committee of the League of Nations on Oct. 11th. This International Office, it will be recalled, was established by the International Convention of Rome, 1907, and its Permanent Committee consists solely of the technical delegates of the participating Governments. The number of States adhering to the Convention of 1907, whether members or non-members of the League of Nations, has increased considerably within the last ten years, with the result that the total of the participating Governments is now 51, and the representation is practically world-wide. The office is principally concerned with technical and administrative matters arising out of the numerous international conventions and agreements on health questions, of which the International Sanitary Convention, 1926, is the chief. Its Permanent Committee, which meets twice a year in Paris, is also the Advisory Council of the Health Organisation of the League of Nations.

Sir George Buchanan will leave at the end of this week for Capetown to attend a conference of State health administrations which is being convened for Nov. 15th on various matters relating to infectious diseases. All the principal British possessions on the east side of Africa, together with Portuguese and one or two other foreign colonies, will be represented, Sir George being present on behalf of the League of Nations.

DRIED AND CONDENSED MILKS

THE problem of milk distribution has lately been forced on the attention of the public. There is little doubt that if agreement had not been reached at the eleventh hour between the producers and distributors in the recent dispute concerning the price to be paid to the farmer for his raw product, there would have been a large, if only temporary, increase in the consumption of dried and evaporated milks in this country. Whatever may be the comparative merits of raw and treated milks, there can be no question as to the value, under certain circumstances, of a supply of milk which can be safely stored for long periods and can be transported readily and cheaply to any part of the world. A good deal of attention has been paid to the scientific problems connected with the manufacture and the nutritive properties of condensed and dried milks; two recent reports[1] of the Hannah Dairy Research Institute deal comprehensively with the whole subject. The first of these is concerned mainly with the chemical and bacteriological problems met with in milk production and in the manufacture of dried and condensed milks; the second deals with the engineering side of manufacture. The aim of both has been to collect all the available information which would aid the manufacturer to turn out economically the best possible product, alike from the point of view of freedom from disease-promoting agents, retention of nutritive properties, and palatability. Special attention is directed to problems, theoretical and practical, which still await solution. The reports should prove invaluable to those engaged in these important industries.

MOSQUITO-PROOFING OF BARRACKS IN INDIA

FOR his presidential address to the United Services Section of the Royal Society of Medicine on Oct. 10th, Group-Captain A. W. Iredell chose the subject of Mosquito-proofing of Barracks by the Royal Air Force in India. The success of this procedure in the Army at Lahore has facilitated similar treatment of R.A.F. barracks at Karachi and near Quetta. The saving in malaria cases was much the same as already reported, but there is the same difficulty as of old in getting money for the purpose. The cost was £8000 at Karachi, which of course appears a large sum, but there are really great savings, as we have already insisted.[1] Estimates are needed from experienced officers of the money saved to the State, in days in hospital saved, in cost of treatment, and in gain of service; for until these facts become well known, administrators are reluctant to spend money, with only a pious hope that the expenses to be met by their successors will be lessened. Mere numbers of cases saved mean little to lay civilians in charge of estimates. Group-Captain Iredell added to his statistical proofs his own statement of the greatly increased comfort of the men, no longer troubled by their mosquito nets and saved from the inconvenience of the many insects other than mosquitoes which are kept out by mosquito-proofing.

WE regret to announce the death on *Oct. 24th* of Mr. A. Freeland Fergus, late honorary surgeon to the Glasgow Eye Infirmary and ophthalmic surgeon to the Glasgow Royal Infirmary.

THE next British Congress of Obstetrics and Gynæcology will be held in Birmingham from April 5th to 7th, 1933, and *not*, as previously arranged, from the 19th to 21st. The main subject of discussion will be the Mechanism of Uterine Action and its Disorders. Any member who wishes to read a paper should send a copy before Dec. 31st to the hon. local secretary, Mr. W. E. Barnie-Adshead, 89, Cornwall-street, Birmingham.

BOGNOR REGIS HOSPITAL.—On Saturday, Sept. 24th, the new *Bognor War Memorial Hospital* was formally opened by Lord Leconfield, the Lord-Lieutenant of Sussex. Mr. James Fleming, to whose generosity the first Bognor hospital, planned 37 years ago, owes so much, has once more given practical support. After the opening ceremony a dedication service was conducted by the Bishop of Chichester. The building has cost £15,000.

POST-GRADUATE LECTURES

The lectures summarised below formed part of the autumn post-graduate courses at London teaching hospitals. Prof. Boycott's was delivered at University College Hospital, Dr. Wilson's at St. Mary's, and those of Dr. Wall, Mr. Cairns, and Dr. Brain at the London.

CANCER OF THE LUNG

(PROF. A. E. BOYCOTT)

THIRTY years ago, in London, "mediastinal tumours" were quite rare; a big hospital might have none or one or two a year, it was difficult to know much about them and we were content to think of them as lymphosarcomas of the mediastinal glands which often grew into the neighbouring parts of the lung. But they were commoner in other places as I learned when I went to Manchester about 1912. We were then realising more and more clearly the importance of chronic irritation in the causation of cancers, and it was natural to associate the prevalence of what we supposed were sarcomas of bronchial glands with the absorption of the irritating particles so abundantly present in the air in those parts. As a matter of fact it seems that the disease was by then becoming more common generally though the increase was not enough to attract attention and comment till about 1922 when workers in many places in England, Europe, and America began to meet with examples of it quite frequently. It is extremely difficult, indeed hardly possible, to get precisely comparable statistics between one hospital and another or between different years at the same hospital, but there is no doubt that on the whole (though not perhaps everywhere) the disease is substantially commoner now than it used to be; in London at any rate it has become commonplace and familiar instead of being a curiosity. This has enabled us to know enough about it to make it interesting.

In the first place, we know, chiefly by the work of W. G. Barnard, that the great majority of "mediastinal tumours" are carcinomata of bronchi. A good proportion are obviously squamous-celled tumours and a few are mucus-forming columnar-celled growths. Careful histological examination of the rest shows that the small round or oval cells of which they are composed are not characteristic and indicative of their origin; here and there more differentiated areas will be found in which polygonal cells and often regular epithelial acini declare the real source of the growth. As a matter of gross anatomy it is also possible, especially with the smaller younger tumours, to see how the tumour begins in the mucosa of the larger bronchi and thence spreads to the glands rather than vice versa as we used to think. It is not at all clear why it does not grow out into the lumen of the bronchus; if it did, early diagnosis might be easier. We have then (1) mediastinal lymphosarcomas, many of which arise in the thymus; (2) carcinomata of bronchi which are much the commonest; and (3) a rare tumour which appears to be a carcinoma of alveolar epithelium.

In the second place, we have had an interesting problem in ætiology to solve and we still have it. Numerical analysis of the more complete data (such as J. B. Duguid did for the records of the Manchester Royal Infirmary) seems to show that the recent increase began long before pathologists took notice of it—somewhere about 1890 or 1900. If that is so, the influenza of 1918–19 and war gases can have had nothing to do with it. Presumably, therefore, the increase has been caused by some change in habits or mode of life or environment. In speculating what this might be, we cannot put aside the very definite evidence, clinical as well as experimental, that an irritant must act for at least about a quarter of the natural span of life before it produces a tumour; the latent period for mule-spinners' cancer is at the least 15 and on the average 35 years of exposure to the effective mineral lubricating oils. These data, it is true, apply to epitheliomas of skin and may not be directly transferable to tumours of mucous membranes. But something of the same kind must surely be true for these also, and in looking for the cause of bronchial cancer we should probably consider what happened towards the end of last century. The environment as a whole has become less carcinogenic; there is more soap and hot water, less irritating food, the air is cleaner, the general standard of life has greatly improved. We have, on the other hand, much more tobacco and more recently petrol engines and tarred roads; whatever the agent, it produces lung cancer much more frequently in men than in women.

In the third place, the increased frequency has led to a much better knowledge of the clinical aspects and to a great improvement in diagnosis. The disease commonly begins in the large bronchi in the root of the lung; it soon spreads to the neighbouring lymphatic glands and metastasises early to distant parts of the body especially the central nervous system and the suprarenals. The primary growth in its early stages causes no symptoms which attract serious attention; there must presumably be a certain amount of cough but that is after all the common condition of most people. As the lung tumour extends, we have dyspnœa, pleurisy, and hæmoptysis. But it is remarkable how various the initial complaint may be and in how many cases it comes from a secondary growth. A man apparently in good health may die from a profuse hæmoptysis or he may spend months in a tuberculosis sanatorium or he may begin with a sudden pleurisy or he may simulate a subacute pneumonia. Or he may slowly develop the classical symptoms of a cerebral tumour or have a sciatica or a hemiplegia or Addison's disease or auricular fibrillation (from direct invasion of the heart) or intestinal obstruction (from secondary glands) or debility without any localising signs. The possibility of cancer of the lung is worth bearing in mind in any queer case.

THE MANAGEMENT OF PULMONARY TUBERCULOSIS

(DR. CECIL WALL)

Laennec said that Nature often cured tuberculosis, but the physician seldom played any part in the cure. We can say no more to-day. We have learned to avoid interference with the natural processes. The hypothesis on which we have to work is that tuberculosis is a local disease which produces general symptoms by the absorption of toxins into the circulation; in this it resembles diphtheria and tetanus, and differs from diseases like scarlet fever and measles in which general disease produces local symptoms. In most cases of tuberculosis the symptoms due to the local disease are unimportant; the interest in Chaucer include the passages in the Parson's Tale dealing with the overlying of children, criminal abortion, and infanticide, the existence of privies, and the success of quack veterinary practice, so amusingly described in the Prologue to the Pardoner's Tale.

THE OFFICE INTERNATIONAL D'HYGIÈNE PUBLIQUE

Sir George Seaton Buchanan, senior medical officer of the Ministry of Health and delegate for the United Kingdom, has been appointed President of the Permanent Committee of the Office International d'Hygiène Publique, in succession to the late Mr. Otto Velghe, secretary-general of the Ministère de l'Intérieur et de l'Hygiène at Brussels. Mr. Velghe had held that office continuously from 1919 until his death at Geneva which occurred suddenly whilst he was attending the session of the Health Committee of the League of Nations on Oct. 11th. This International Office, it will be recalled, was established by the International Convention of Rome, 1907, and its Permanent Committee consists solely of the technical delegates of the participating Governments. Group-Captain Iredell added to his statistical proofs his own statement of the greatly increased comfort of the men, no longer troubled by their mosquito nets and saved from the inconvenience of the many insects other than mosquitoes which are kept out by mosquito-proofing.

WE regret to announce the death on Oct. 24th of Mr. A. Freeland Fergus, late honorary surgeon to the Glasgow Eye Infirmary and ophthalmic surgeon to the Glasgow Royal Infirmary.

THE next British Congress of Obstetrics and Gynæcology will be held in Birmingham from April 5th to 7th, 1933, and not, as previously arranged, from the 19th to 21st. The main subject of discussion will be the Mechanism of Uterine Action and its Disorders. Any member who wishes to read a paper should send a copy before Dec. 31st to the hon. local secretary, Mr. W. E. Barnie-Adshead, 89, Cornwall-street, Birmingham.

BOGNOR REGIS HOSPITAL.—On Saturday, Sept. 24th, the new Bognor War Memorial Hospital was formally opened by Lord Leconfield, the Lord-Lieutenant of Sussex. Mr. James Fleming, to whose generosity the first Bognor hospital, planned 37 years ago, owes so much, has once more given practical support. After the opening ceremony a dedication service was conducted by the Bishop of Chichester. The building has cost £15,000.

POST-GRADUATE LECTURES

THE lectures summarised below formed part of the autumn post-graduate courses at London teaching hospitals. Prof. Boycott's was delivered at University College Hospital, Dr. Wilson's at St. Mary's, and those of Dr. Wall, Mr. Cairns, and Dr. Brain at the London.

CANCER OF THE LUNG

(PROF. A. E. BOYCOTT)

THIRTY years ago, in London, "mediastinal tumours" were quite rare; a big hospital might have none or one or two a year, it was difficult to know much about them and we were content to think of them as lymphosarcomas of the mediastinal glands which often grew into the neighbouring parts of the lung. But they were commoner in other places as I learned when I went to Manchester about 1912. We were then realising more and more clearly the importance of chronic irritation in the causation of cancers, and it was natural to associate the prevalence of what we supposed were sarcomas of bronchial glands with the absorption of the irritating particles so abundantly present in the air in those parts. As a matter of fact it seems that the disease was by then becoming more common generally though the increase was not enough to attract attention and comment till about 1922 when workers in many places in England, Europe, and America began to meet with examples of it quite frequently. It is extremely difficult, indeed hardly possible, to get precisely comparable statistics between one hospital and another or between different years at the same hospital, but there is no doubt that on the whole (though not perhaps everywhere) the disease is substantially commoner now than it used to be; in London at any rate it has become commonplace and familiar instead of being a curiosity. This has enabled us to know enough about it to make it interesting.

In the first place, we know, chiefly by the work of W. G. Barnard, that the great majority of "mediastinal tumours" are carcinomata of bronchi. A good proportion are obviously squamous-celled tumours and a few are mucus-forming columnar-celled growths. Careful histological examination of the rest shows that the small round or oval cells of which they are composed are not characteristic and indicative of their origin; here and there more differentiated areas will be found in which polygonal cells and often regular epithelial acini declare the real source of the growth. As a matter of gross anatomy it is also possible, especially with the smaller younger tumours, to see how the tumour begins in the mucosa of the larger bronchi and thence spreads to the glands rather than vice versa as we used to think. It is not at all clear why it does not grow out into the lumen of the bronchus; if it did, early diagnosis might be easier. We have then (1) mediastinal lymphosarcomas, many of which arise in the thymus; (2) carcinomata of bronchi which are much the commonest; and (3) a rare tumour which appears to be a carcinoma of alveolar epithelium.

In the second place, we have had an interesting problem in ætiology to solve and we still have it. Numerical analysis of the more complete data (such as J. B. Duguid did for the records of the Manchester Royal Infirmary) seems to show that the recent increase began long before pathologists took notice of it—somewhere about 1890 or 1900. If that is so, the influenza of 1918–19 and war gases can have had nothing to do with it. Presumably, therefore, the increase has been caused by some change in habits or mode of life or environment. In speculating what this might be, we cannot put aside the very definite evidence, clinical as well as experimental, that an irritant must act for at least about a quarter of the natural span of life before it produces a tumour; the latent period for mule-spinners' cancer is at the least 15 and on the average 35 years of exposure to the effective mineral lubricating oils. These data, it is true, apply to epitheliomas of skin and may not be directly transferable to tumours of mucous membranes. But something of the same kind must surely be true for these also, and in looking for the cause of bronchial cancer we should probably consider what happened towards the end of last century. The environment as a whole has become less carcinogenic; there is more soap and hot water, less irritating food, the air is cleaner, the general standard of life has greatly improved. We have, on the other hand, much more tobacco and more recently petrol engines and tarred roads; whatever the agent, it produces lung cancer much more frequently in men than in women.

In the third place, the increased frequency has led to a much better knowledge of the clinical aspects and to a great improvement in diagnosis. The disease commonly begins in the large bronchi in the root of the lung; it soon spreads to the neighbouring lymphatic glands and metastasises early to distant parts of the body especially the central nervous system and the suprarenals. The primary growth in its early stages causes no symptoms which attract serious attention; there must presumably be a certain amount of cough but that is after all the common condition of most people. As the lung tumour extends, we have dyspnœa, pleurisy, and hæmoptysis. But it is remarkable how various the initial complaint may be and in how many cases it comes from a secondary growth. A man apparently in good health may die from a profuse hæmoptysis or he may spend months in a tuberculosis sanatorium or he may begin with a sudden pleurisy or he may simulate a subacute pneumonia. Or he may slowly develop the classical symptoms of a cerebral tumour or have a sciatica or a hemiplegia or Addison's disease or auricular fibrillation (from direct invasion of the heart) or intestinal obstruction (from secondary glands) or debility without any localising signs. The possibility of cancer of the lung is worth bearing in mind in any queer case.

THE MANAGEMENT OF PULMONARY TUBERCULOSIS

(DR. CECIL WALL)

Laennec said that Nature often cured tuberculosis, but the physician seldom played any part in the cure. We can say no more to-day. We have learned to avoid interference with the natural processes. The hypothesis on which we have to work is that tuberculosis is a local disease which produces general symptoms by the absorption of toxins into the circulation; in this it resembles diphtheria and tetanus, and differs from diseases like scarlet fever and measles in which general disease produces local symptoms. In most cases of tuberculosis the symptoms due to the local disease are unimportant; the toxæmic symptoms are those which we have to combat and which will give guidance in the management of the case. Most patients in whom the disease is partially arrested will get a warning symptom of a relapse. The warning symptom varies in different patients; in one it may take the form of increased cough, in others of pains in the chest, insomnia, malaise, or headache. It is important to note the warning symptom in each patient and to initiate treatment at once. Fatigue is the common cause, rest the usual treatment.

Three methods of controlling tuberculosis suggest themselves :

(*a*) Attempts to reduce the quantity of toxins reaching the circulation.
(*b*) Attempts to neutralise the toxins by producing active or passive immunity.
(*c*) Chemotherapy. This is probably the method of the future, but the ideal drug which will kill the organism in the lesion has not yet been discovered.

It has long been known that rest is the important thing in the treatment of tuberculosis. Dr. Marcus Paterson many years ago introduced treatment by absolute rest ; the febrile patient was kept motionless in bed and was not even allowed to feed himself. This was a great advance in treatment, and was followed by attempts to put the focus of disease at rest by collapsing the lung by means of artificial pneumothorax, by oleothorax, avulsion of the phrenic nerve, and thoracoplasty. The general practitioner is chiefly concerned with the treatment of the patient after he has left the sanatorium. He must be made to rest at once on the appearance of a warning symptom ; relapses are due to neglect of these warnings.

Attempts to procure specific immunity by means of tuberculin have never been satisfactory. The patient who has recovered from the disease is more likely than the ordinary person to acquire another tuberculous lesion later in life. Tuberculin can be used to raise the patient's resistance against tuberculotoxæmia, and does relieve symptoms to some extent. As regards chemotherapy, sanocrysin seems to benefit certain cases, but there are many contraindications to its use, and many patients appear to have idiosyncrasy to it, so that the number of cases in which it can be used with advantage is limited.

The general treatment consists of rest, fresh air, and good food. Rest is essential ; an overdose cannot do harm. Marcus Paterson thought that immunity could be induced by releasing into the patients circulation at intervals a certain amount of tuberculin from the lesion itself, and introduced the system of graded exercises. The hypothesis was incorrect but the treatment was sound ; graded exercises act as a test of progress. Emotional excitement must be classed with exercise.

Sanatoriums provide a healthy, regular life under continual supervision more cheaply than it can be obtained in the patient's home ; moreover, they provide the element of mental rest which can never be attained in the bosom of one's family. The patient, when he begins to get about, has the advantage of companionship with people who have to grade their output like himself. He will not be discouraged by the sight of patients with symptoms, because in a well-run sanatorium such patients will be kept out of sight in bed. Clean air is valuable, but complete exposure to open air in all weathers is undesirable. The public think immediately of Switzerland when tuberculosis is mentioned ; many Swiss sanatoriums are good, but they seldom have grounds attached to them, consequently patients are beyond the supervision of the superintendent when they go out for exercise. English sanatoriums have good grounds, and it is advisable to send the patient to an English sanatorium in the early stages, and to Switzerland, if he wishes, for convalescence. Burney Yeo's aphorism holds good : "Care without climate is better than climate without care." A patient should not go to Switzerland unless he can afford to live comfortably when he gets there. There are disadvantages in the tropics for these patients, but they have the recommendation that appointments there are fairly easily obtainable in which the patient will be able to sit still and direct other people. In parts of South Africa the dust is a disadvantage, and patients do not do well ; in British Columbia, California, the Argentine, and Nairobi, however, the benefit of climate is great.

An occupation in which the patient is his own master and can slacken work when necessary suits these cases best. There is a prevalent idea that people with tuberculosis should live in the country, and many move out of town, coming in by train daily ; a few can stand the double train journey in addition to the day's work, but most of them will do better by staying in town. Again, some patients, impressed with the importance of fresh air, go for a long bicycle ride after their work ; they would do much better to rest. A philanthropic society used to get patients after leaving sanatoriums posts as 'bus conductors, until it was found that conductors traverse about 15 miles a day at a jog-trot up and down stairs. The same society also tried to turn clerks into farm labourers at a wage of 28*s*. a week. A farmer estimated that a man loading hay had to lift about three tons a day. The strength of the patient is not equal to the task, and the standard of living at such a wage is too low ; such experiments are doomed to failure.

A good mixed diet with a four-hour interval between meals suits these patients best. The old fad for giving them enormous quantities of milk—four pints a day—only led to dyspeptic symptoms, and has now been abandoned. If the patient likes extra milk and can take it let him have it, but never force it upon him. The amount of vitamins necessary to satisfy nature is so small that there is no reason to add them specifically to a good general diet. Salad dressed with olive oil is a useful means of introducing extra fat into the diet. Many cases of alcoholism owe their origin to tuberculosis ; the patient drinks to get rid of the sense of fatigue. Alcohol in small quantities, however, may be useful to stimulate appetite, and in older people, accustomed to alcohol, it is of decided value, causing vasodilatation and easing the action of the heart.

TREATMENT OF COLI BACILLURIA BY A KETOGENIC DIET

(Dr. C. M. Wilson)

Infection of the urinary tract by the colon bacillus is common, and a substantial minority of those who suffer from this infection fail to respond to either medical or surgical treatment. In May I had qualified for membership of that minority by seven months ineffectual search for relief, when Prof. Cabot was good enough to give me the proportions of fat, carbohydrates, and proteins in the ketogenic diet with which Clark and Helmholtz had reported encouraging results.

On the third day the urine was nearly clear ; by the end of the sixth day it was reported sterile. I remained on the diet for another week and then ate anything. Since that date four months have passed without a recurrence of the infection.

I shall try to tell you how the diet may be made comparatively inoffensive to the patient, and what results have been obtained in the treatment of 20 adults with *B. coli* infection of the urinary tract, who were deliberately chosen on account of the chronicity of the infection. The diet used has been varied with the patient, but the proportions of protein, fat, and carbohydrate have remained fairly constant: 60 g. of protein, 240 g. of fat, and 20 g. of carbohydrate. It would be idle to pretend that patients like the diet, but with care and a little imagination it can be robbed of most of its disagreeable features. We have to reconcile them to 240 g. of fat in the day, and to the almost total deprivation of carbohydrates. Protein is given in the normal amount.

If fat is disliked in one form, it can be given in another. Let us suppose the 240 g. of fat are given as :—

10 oz.	cream 40 per cent.	containing	100	grammes of fat.
3½ ,,	butter	,,	90	
2 ,,	fat bacon	,,	36	

The remainder of the fat is taken in meat and eggs. It is the butter and cream to which most patients object. If a jug of cream and a slab of butter with some diabetic biscuits are presented to the patient he will soon quarrel with the diet. As much as possible of both butter and cream should be used in cooking. A vegetable cream soup and a fruit fool will not leave much cream to be taken with tea or coffee. In my experience of the diet I found the butter a stumbling-block. As we shall see presently, we have no carbohydrate to spare for breadstuffs or biscuits. There are two alternatives: to eat the butter with diabetic biscuits, or to use it in cooking in a vegetable purée, in buttered eggs, or in an omelette. If it is desired to reduce the butter or cream, half an ounce of olive oil night and morning will supply 30 g. of fat and provide a substitute.

Only 20 g. of carbohydrate are allowed, and of this 10 g. have been used in the cream. The remaining 10 g. can be taken as fruit, a good vehicle for cream; or 5 g. may be given as fruit and 5 g. as milk in a custard, junket, or milk-jelly. In the American literature the patient is gradually broken into the diet by substituting fat for carbohydrates over some days, but this of course prolongs the agony, and in my experience embarking straightway on the full diet seldom leads to nausea.

However cunningly the diet be planned, the patient will ask how long he must endure it. In long-standing infection one to three weeks is commonly necessary to sterilise the urine. Most of my patients have continued the diet for a week after the urine was sterile. We do not yet know if it is necessary to persevere longer with the diet to avoid relapses. I find no mention of relapses in the American literature, but in one of my cases, a woman who did not attempt to diet after the urine had been sterile for four days, the infection returned a month later, to respond again to the diet. The permanence of these results has yet to be established.

In the absence of fever, exercise assists the oxidation of fat and helps the ketosis to develop. If the infection is associated with fever the patient may have difficulty in dealing with the diet, but this does not necessarily follow. Occasionally we have to await the fall of the temperature before dieting. The intake of fluids should not exceed the normal.

To cure a malady that has long resisted medical and surgical measures by nothing more troublesome than a typed diet sheet is sufficiently attractive to obscure for a moment the time and trouble essential to success in a treatment dependent on exact quantitative dieting. It is not enough to prescribe a diet high in fat and low in carbohydrates. Everything must be weighed. Apart too from the time absorbed in planning the diet in the required proportions and in presenting it in a palatable form, the practitioner may find it difficult to get the pH of the urine estimated. The pH of the urine of a person who is on a mixed diet is commonly between 6·0 and 7·0, precisely the pH most favourable to the growth of *B. coli.* Schohl and Janney found that colon bacilli are inhibited from growing in urine with a pH 4·6 to 5 on the acid side and 9·2 to 9·6 on the alkaline side. It is the purpose of the ketogenic diet to lower the pH to 5 or less. If the pH remains at 6 for example, either the patient belongs to the small minority who cannot digest or assimilate the amount of fat necessary to produce the ketone bodies in the urine, when the treatment must be abandoned, or the patient is not adhering strictly to the diet. Without the assistance of the pH one is working in the dark; the patient may be dieted for two or three weeks without once obtaining the pH necessary to inhibit the growth of the colon bacillus. It is as if one treated diabetes with only the symptoms of the disease as guidance and without any knowledge of the presence or absence of sugar in the urine.

We have found occasionally that the urine has been sterile before the pH fell to 5·0 or less. W. M. Clark noticed this and concluded that in a highly buffered medium such as urine while the hydrogen-ion concentration is the chief limiting factor, the urine may contain substances that have a bactericidal action independent of their acidity. But in practice estimations of the pH warn one when the conditions essential to success are absent, or enable one to assure the patient that perseverance with the diet will be rewarded.

Helmholtz has had very encouraging results with children, but I shall confine my remarks here to adults, and to adults in whom the infection has become chronic. During the past four months I have treated 20 patients in whom the duration of the infection with the colon bacillus has varied from 7 months to 18 years. From such a small number so recently discharged only tentative conclusions can be made. One patient relapsed as I have recorded, the urine again becoming sterile after renewed dieting. The course of the remainder was uneventful. The urine in all became sterile and has remained sterile. Early writers in American literature wrote that if the kidney is considerably damaged by infection the patient may be unable to secrete enough ketone bodies or to secrete a sufficiently acid urine to inhibit the growth of the bacteria. In my experience the duration of the infection has never been a barrier to the sterilisation of the urine. Moreover, tests of the functional efficiency of the kidney in these prolonged infections showed no impairment of function. Sufficient time has not elapsed to establish the permanency of these results, yet as they stand they are remarkable.

Mrs. A., aged 54. In 1914 after the birth of her second child had a severe attack of pyelitis with pus and colon bacilli in the urine. She was in bed for three months. From that date there is a history of severe attacks of pyelitis at intervals with severe renal pain and rigors. In 1925 the urinary tract was washed out with temporary improvement; this was repeated several times subsequently. From 1928 to 1931 the attacks had increased in frequency and severity. Early in June of this year she was given a ketogenic diet.

The pH came down to 5·0 and 5·2, but rose again gradually to 5·4 and 5·6 without any relaxation of the diet. On the 24th day of the treatment the urine was sterile. Her husband, a doctor, reported nearly four months later, "has greatly improved, no longer a chronic invalid, has put on 12 lb. in weight and the urine is still sterile." Hexamine, alkalis, urotropine, Caprokol, Cystopurin, Neotropin, Pyridium, and vaccines had been given a prolonged trial. From 1905 there was a history of severe sinus infection with repeated washings out of both antra, a radical operation on the ethmoid and sphenoidal cells, and finally the drainage of the right frontal sinus. While on the diet the advisability of further surgical measures was under consideration.

In another patient in whom the infection dated back 16 years the urine became sterile in three and a half weeks. A third woman with a history of repeated attacks over 13 years had had the urinary tract washed out in 1920, 1922, 1928, 1929, and 1930. The colon bacilli responded to the dieting, but a streptococcal infection of the urinary tract persisted. A fourth patient with an infection dating from a pregnancy four and a half years ago had sterile urine on the 23rd day. In a man who had had an innocent vesical papilloma removed and later after a stone had been extracted from the bladder had developed a fistula, an infection with Morgan's bacillus proved rather more obstinate, but the urine was found to be sterile after six weeks.

In bacilluria a large number of different gram-negative organisms are found. Of these the growth of the colon bacillus is most readily inhibited by the ketogenic diet. A bacteriological examination of the urine was carried out once a week by Captain Hayden. A positive ferric chloride test was accepted as evidence of an adequate ketosis. The use of the ketogenic diet over long periods in the treatment of epilepsy had brought assurance that no ill-effects followed the diet and none was noted in our experience. Most of the patients lost a few pounds in weight probably as the result of dehydration.

HEAD INJURIES AND THEIR SEQUELS

I.—(Mr. Hugh Cairns)

II.—(Dr. W. Russell Brain)

I.—In dealing with acute head injuries it is as well to move the patient straight from the scene of accident into a hospital or nursing home if possible. It is easier to impose rest upon the patient when in hospital, and besides it is impossible to say at the outset whether a case is going to need operation or not. On the way to the ward, have the skull of the patient radiographed. Although in recent years the amount of injury to the brain, and not the presence of fracture of the skull has come to be regarded as the important factor, this is not appreciated in a court of law, and the jury will always want to know whether the skull was fractured. Besides this, X rays will demonstrate the presence of a depressed fracture, and may show some unusual condition which would *otherwise be missed.*

One patient, a chauffeur, had been thrown head-on to a lamp-post. He was unconscious for five days, and on recovery showed signs of damage to the right optic and olfactory nerves. Some weeks later he developed weakness of the left arm and leg. Radiography showed a quantity of air inside his skull, and fracture of the right frontal sinus. He passed cerebro-spinal fluid from his nose whenever he sat up. *At operation* he was found to have an aerocele of the right frontal lobe of the cerebrum; a hollow needle was inserted and the brain collapsed with a puff. The dura had to be closed so as to prevent the further escape of cerebro-spinal fluid.

A man passing cerebro-spinal fluid from the nose is living on a volcano. In this case striated muscle-fibres were found in the fluid passed on the first day, which proved to have come from the sausage the patient had eaten or breakfast. The danger of infection of the meninges in such a case is naturally very great.

The first thing to do with a patient with an acute head injury is to put him to bed in a darkened room and to decide whether he needs to be treated medically or surgically. Routine observations must be made hourly of the pulse, temperature, and respiration, the state of unconsciousness—whether the patient is deeply unconscious or only stuporose—the state of the pupils, and any indications of paralysis. These observations must be committed to paper, for otherwise it is extremely difficult to avoid confusion after two or three hours. The general treatment for mild and doubtful cases is to ensure rest and give sedatives; a decompression can be undertaken if the symptoms require it.

A wound of the head may involve the scalp only or may lie over a fracture with injury to the dura. The patient with a head wound should be taken to the operating theatre as soon as he has recovered from shock, and the hair should be shaved away over a wide area round the injury. When the wound has been cleaned the underlying *bone must be examined.* If a linear fracture is present it is usually safe to leave it alone, but if there is any overlapping, however slight, a piece of bone must be taken out to see what is underneath. In one case, where the two edges of the fracture had slipped back almost into apposition after the accident, a quantity of manure was found inside the skull, having entered at the instant during which the bone gaped in the moment of injury. Foreign matter can be removed best by a suction apparatus. If the dura is torn it must be opened up and the underlying region must be cleaned with the suction apparatus. The wound must be drained; the dura should be loosely sutured and the drainage-tube brought down to, but not through it. Anti-tetanic serum should be given while the patient is under the anæsthetic; the head bandage must be firm and can be given a covering of plaster-of-Paris, since these patients are sometimes violent when they recover consciousness. It is an open question whether operation should be undertaken *for simple depressed fracture.* If the depression of the fracture is deep it is advisable to operate, but there is no necessity for urgent action.

Tearing of the middle meningeal artery is rare, and too much emphasis has been laid upon it as a cause of intracranial hæmorrhage. The striking course which these cases run has helped to make them notable. The patient has a slight head injury, is concussed for a moment and then appears to make a complete recovery; after a few hours he loses consciousness and may show Jacksonian fits. Intracranial hæmorrhage from other vessels, however, produces rapidly deepening unconsciousness after a lucid interval in the same way. The treatment is to make a small hole in the skull and look for a clot; it is commoner to find a subdural than an extradural hæmorrhage. If a clot is found the hole must be enlarged and the blood sucked out.

Intracerebral hæmorrhage sometimes occurs from *direct injury, for example* when a baby at a cricket match receives a boundary hit on the skull. Symptoms may include advancing paralysis, sensory loss, and papillœdema. In such cases it is worth operating for intracerebral hæmorrhage, for it is possible to remove the clot. In cases of focal contusion, though it is not essential, it may be useful to operate, because decompression helps the condition to clear up, and if it is performed under the temporal muscle the bone defect can be well protected. Chronic subdural hæmatoma often follows a trivial rather than a severe head injury. About a month after the accident the patient becomes irritable and drowsy and complains of headache and weakness of one arm and leg. A gradually enlarging clot is pressing on the surface of the hemisphere causing these slowly advancing symptoms. The bleeding is usually from cerebral veins which have been torn as they go through the dura to the longitudinal sinus. The treatment is to make a small hole on each side of the skull and, when the clot is located, to suck it out. Only exceptional cases of head injury need surgical treatment; in most cases operation plays no part.

(Dr. W. Russell Brain)

II.—Concussion is a paralysis of part of the function of the central nervous system due to a blow on the head. Recovery takes place unless the vital centres in the medulla are paralysed. Cerebral contusion is the commonest form of head injury; it is associated with hæmorrhages of varying size scattered through the cortex, and œdema round the nerve-cells and in the perivascular spaces. Laceration is a breach in continuity of the brain substance, usually the cortex, which may give rise to focal symptoms. Traumatic cerebral compression is usually due to hæmorrhage.

In mild cases the patient with concussion is dazed; he may finish playing a game of football and recall nothing of it afterwards. In more severe cases he loses consciousness and may die from medullary paralysis; most patients, however, recover within 48 hours. Contusion may occur without concussion, but in severe cases the patient is concussed as well. After recovering consciousness the patient becomes confused, irritable, and excitable, and may complain of headache; occasionally mental symptoms persist and a mild maniacal condition supervenes.

One patient of this kind whenever he met three people walking together in the street felt impelled to attack them, though two or four left him undisturbed; he also felt moved to plunge table knives into people in order to experience the sense of suction as he drew the knife out of the flesh.

In other cases there may be monoplegia and sensory or visual symptoms. An important group of patients are those with symptoms due to contusion of the mid-brain; there may be diplopia, mild cerebellar symptoms or, rarely, symptoms of diabetes insipidus. Mild forms of this appear to be commoner after head injury than is generally suspected. The urinary output should therefore be measured in all cases. In severe cases pituitrin will be required indefinitely.

Focal lesions of the spinal cord may also follow a blow on the head, and hæmorrhage into the spinal cord should be borne in mind when symptoms of paralysis develop after a head injury. Lumbar puncture should be performed in all cases of head injury, and in severe cases blood will be found in the cerebro-spinal fluid. The pressure of the fluid should be measured with a manometer; it will usually be raised but sometimes it is subnormal, and here the treatment has to be modified slightly, as I shall presently describe.

Concussion is rarely fatal. Contusion may prove fatal, but is more important as a cause of prolonged disability. In one series of cases of contusion it was found that 10 per cent. of the patients were totally incapacitated, and more than half were unable to return to their normal occupations.

The treatment of concussion is to keep the patient in bed in a darkened room and give sedatives and analgesics; a saline purge helps to relieve the intracranial pressure. Three or four days at least should be spent in bed, and longer if possible, because some degree of contusion may also be present. Even mild cases of contusion require three or four weeks in bed. The method of cerebral dehydration by intravenous injection of hypertonic solutions of salt or glucose is disappointing; the perivascular spaces in the brain are probably too closely packed with blood or œdema for the normal mechanism of absorption to act. There is no harm in giving hypertonic solutions of magnesium sulphate by the rectum.

If, on performing lumbar puncture, the pressure of the cerebro-spinal fluid is found to be raised the patient will be more comfortable propped up with pillows; if, on the other hand, the pressure is low, the patient should lie flat without a pillow and with the foot of the bed raised on blocks; he should also be given plenty of fluid, drinking, if possible, a gallon a day. Air can be injected into the spinal canal through a lumbar puncture needle to raise the pressure, but I have found this method disappointing.

Often people who have had head injuries complain of disabling symptoms when they are up and about again. Paroxysmal pain in the head, worse on stooping, is a common complaint, and giddiness, irritability, nervousness, and incapacity for work are other symptoms. These symptoms are organic and not due to neurosis. Prolonged rest in bed is required in such cases; and bromide and magnesium sulphate should be given.

Other late effects of head injuries are cranial nerve palsies. Each nostril should be tested separately for loss of the olfactory sense, since anosmia usually indicates a fracture involving the anterior fossa.

Injury of the optic nerve is followed by atrophy of the damaged fibres and a corresponding permanent impairment of vision. The prognosis is disappointing when there is injury to the nerves supplying the muscles of the eyeball. The seventh and eighth nerves may be involved in fracture of the mastoid process, and are then unlikely to recover; but branches of the fifth and seventh nerves may be contused by a blow on the face, and in these cases complete recovery occurs.

Traumatic epilepsy is comparatively rare in civil life; during the war 5 to 10 per cent. of cases developed the condition following gunshot wounds of the head. It is most likely to arise when the dura has been torn and formed scars. The treatment should be medical for at least two or three years, and only in exceptional cases should surgical interference be considered.

New Sussex Hospital for Women, Brighton.—On Oct. 11th Lady Campion, chairman of the governors, reopened a ward which for two years had been closed but which Mr. C. H. Corbett, the hon. treasurer, has now redecorated and re-equipped in memory of his wife. It will be known as the Marie Corbett ward, and be used for patients reaching the convalescent stage, in whom Mrs. Corbett had always been greatly interested.

Reduced Costs at Coventry.—During the first eight months of the present year the cost of provisions at the Coventry and Warwickshire Hospital has been reduced from £5652 in the corresponding period of last year to £4383. There has also been a saving at the Alcock Convalescent Hospital. The cost per patient per day at the main hospital has thus been lowered from 21·4*d.* to 16·3*d.* Supplies are now purchased personally by members of the staff in the market.

MEDICINE AND THE LAW

Criminal Abortion : Evidence of Previous Conviction

Richard William Starkie, sentenced at the Central Criminal Court last July on a charge of having unlawfully used an instrument with intent to procure miscarriage, has been refused leave to appeal. His application for this purpose, disposed of by the Court of Criminal Appeal on Oct. 17th, raised a novel and interesting point. His counsel at the trial had elicited the fact that the accused had once been a registered medical practitioner; the fact that his name had been struck off the Medical Register (under Section 29 of the Medical Act) was thus disclosed, but was apparently explained by a statement that he had fallen foul of the medical authorities. Did this amount to giving evidence to establish his own good character? If so, it enabled the prosecution to cross-examine him as to a previous conviction in 1921 for administering drugs with intent to procure miscarriage. Starkie asked for leave to appeal on two grounds, one of which was that this cross-examination should not have been allowed.

The Criminal Evidence Act of 1898, which enabled accused persons to go into the witness-box and give evidence on their own behalf, enacted that. with certain exceptions, they must not be asked any question tending to show that they are of bad character or have committed, or have been convicted of, any offence other than that with which they are charged. One of the specified exceptions allows such questions if the accused has given evidence of his good character, or if the nature or conduct of the defence is such as to involve imputations on the character of witnesses for the prosecution. The scope of this exception is not easy to define. If a man accused of rape suggests that the prosecutrix consented, he can be cross-examined as to previous convictions. On the other hand, if the accused merely says that the prosecutor is a liar or complains that a constable, in arresting him, used improper violence, or alleges that the police have fabricated their evidence, these suggestions have been held not to justify cross-examination as to previous offences. In general, of course, those who administer criminal law in England are scrupulous in maintaining the principle that the fact that a man has committed one crime is not to be taken as evidence that he has committed another. In 1912 an appeal was allowed where a previous conviction had been elicited by questions put by the judge himself at trial while he was trying to help the accused to defend himself. In Starkie's case it might possibly have been argued that for him to give evidence of his name having been removed from the Medical Register amounted to establishing bad character rather than good. Apparently, however, it was taken to have involved an attempt to suggest that he was right and the General Medical Council was wrong. At any rate, Mr. Justice Goddard, in announcing the decision to refuse leave to appeal, said "in the opinion of the Court the applicant was rightly cross-examined as to his previous character because he had put his character in issue by stating that he had been a registered medical practitioner and had fallen foul of the Medical Association."

The other ground of Starkie's unsuccessful application was that the trial judge had not, in his summing-up, dealt fully enough with the defence. Starkie's defence was that he was treating a girl whom he did not know to be pregnant. The Court of Criminal Appeal ruled that the trial judge had fairly and fully put the case for the defence as well as the case for the prosecution. It was clear that there was evidence before the jury, which they were entitled to accept if they saw fit, that the girl had had a miscarriage and that an instrument had been used upon her. The only remaining question was whether Starkie was the person who used the instrument. The girl's evidence was corroborated, and there was abundant evidence on which the jury could find that the accused had committed the offence. The Court of Criminal Appeal does not sit to re-try cases. If the proceedings at the trial were in order, and there was adequate evidence on which the jury could find a verdict of guilty, and if the judge's summing-up reasonably covers the necessary ground and does not go wrong in stating the law, the appellate tribunal declines to interfere.

AUSTRALASIA

(FROM OUR OWN CORRESPONDENT)

TROPICAL DISEASE IN THE COMMONWEALTH

AUSTRALIA's tropical dependencies contain a larger purely white population than any other tropical country, and comprise an area of 1,332,320 square miles. In a presidential address to the section of medicine of the Australian and New Zealand Association for the Advancement of Science, which met in Sydney in August, Dr. R. W. Cilento pointed out that the Australian tropics are of the greatest importance to the Commonwealth because they are within easy striking distance of the world's largest endemic centres of small-pox, cholera, and plague, besides which there is the problem of malaria, dysentery, yellow fever, dengue, ankylostomiasis, and filariasis. Malaria seems to have been introduced by the Malays from the Dutch East Indies, and apparently there was no indigenous disease in the northern part of Australia during the early period of settlement. At a later period Pacific island natives were imported to work on the Queensland plantations and a large number of Chinese were introduced, and it was to this influx of aliens that Australia owed its tropical diseases. This is evidence, Dr. Cilento remarked, not so much of the unsuitability of the tropics for white men, but of the results that follow the introduction among them of a disease-ridden class of coloured indentured labour. The introduction of these aliens was discontinued when the White Australia policy was adopted.

Malaria occurs in the north-west and in two areas in Queensland. Although this is probably an unimportant part of Australia, there is a possibility of its becoming dangerous, Dr. Cilento thinks, should there be any sudden concentration of population in the endemic areas, or if hygienic control is slackened. Filariasis was probably introduced with Kanaka labour in 1863, and now 40–60 cases are admitted annually to the Brisbane Hospital, while it has been found that 15 per cent. of the patients in the surgical wards of the Brisbane Hospital are infected with microfilarial disease. Inland towns are apparently unaffected. Elephantiasis is very rare in Queensland, and as a result of the measures taken in treatment and prophylaxis the incidence of hookworm in that State had greatly decreased, so that it now appeared to be under control as far as the white population was concerned. Amongst the other diseases found in the north-eastern part of Queensland were typhoid, paratyphoid, endemic dengue fever, endemic typhus fever (Brill's disease). An increase in the number of known lepers in North Queensland and in the Northern Territory had taken place, and food-deficiency disease and trachoma were still to be found.

Experienced observers, Dr. Cilento said, have no doubt of the ability of white persons to adapt themselves to tropical climates, and the successful colonisation of tropical parts of Australia is essentially a problem of applied public health.

DEPOPULATION IN THE PACIFIC

Sir Hubert Murray, president of the Association, said that there is no evidence of any alteration during the last hundred years in the total population of Papua, of which he is Lieutenant-Governor. In the eastern and south-eastern divisions of the island, however, the population is known to be declining, and the fall is attributed, amongst other things, to a general shortage of food. He alluded to the belief among women that their children are killed by evil spirits, but spoke of a strong public opinion that there is something disgraceful in having a large family. Sir Hubert himself laid most stress on insufficient food-supply, sickness, and the passing of the old native customs. So far as Papua was concerned, it is expected that some tribes will die out altogether, but that the more resistant stocks will remain, and their natural increase will be more than sufficient to make up any loss.

In New Zealand, said Dr. Wi Repa, before the invasion by western civilisation, the Maori were a healthy race. The change from the old order to the new suddenly bridged a gulf of centuries, and the people found some difficulty in adapting themselves. War, pestilence, sterility, high infantile mortality, and the loss of ancestral lands caused such a decrease that at one time it was feared that the race would die out. But since the beginning of this century the Maori population has increased.

Dr. Cilento maintained that where the natives are only rarely visited by the white men they flourished, but the influence of contact with Europeans, with its restriction of many of the native customs, results for the most part in decline. Conditions in New Guinea have convinced him that the three main factors of depopulation are the heavy infantile death-rate, the considerable mortality at all ages from preventable diseases, and the fact the most of the people live on a borderline diet alternating between periods of plenty and periods of actual starvation. The various permanent causes in operation are introduced or aggravated disease (especially malaria or tuberculosis), bad sanitation, privation, and poverty of diet, and as a consequence lessened fertility with frequent miscarriage, deliberate abortion, and infanticide. The idea that a foreign race would revivify a weak or unhealthy population by introducing new blood is, he thinks, a fallacy. Dr. Raymond Firth discussed particularly the natives of the island of Tikopia, where the population tends to increase, but is limited by celibacy, contraception, abortion, and infanticide. Here epidemics occur only after the occasional visit of some vessel. Mr. E. W. P. Chinnery believed that intensive medical supervision, a properly organised scheme for infantile welfare, and the introduction of new plant foods would do much to reduce the mortality.

According to Mr. Burton, native policy in Australia has resulted in a decline of the aboriginal population from 300,000 in 1788 to 62,000 in 1930—or 80,000 if half-castes are included. He urged that caution and care should be exercised by Australia in her management of the races in the mandated territory.

RESUSCITATION IN DROWNING

In opening a discussion on resuscitation in drowning, Prof. H. Whitridge Davies said that tests showed that the Schafer method of resuscitation, as ordinarily applied, gives more than adequate ventilation of the lungs. He had investigated the extent to which dehydration occurred in drowning, and had found an increased salinity in the blood on the left side of the heart in animals drowned in salt water. The experiments strongly favour the giving of large quantities of water to patients after resuscitation. He also advises the administration of 5 per cent. carbon dioxide in oxygen during resuscitation, and demonstrated an apparatus which he had devised for this purpose. Dr. V. M. Coppleson said that on the Sydney beaches during the past four years in a large number of rescues, resuscitation had been necessary in 74 cases, and there had been 2 deaths. On country beaches there had been 146 resuscitations with 9 deaths. It was apparent that two kinds of training were necessary, according to whether the measures were to be taken by an isolated person or by one with ample assistance, as on the larger beaches. The rubbing of patients, as advocated by the Surf Life Saving Association and the Royal Life Saving Society, is, he said, an anachronism, and the covering of patients with warm blankets or clothing and drying them is of infinitely greater value.

The statement was made that one might expect an excess of carbon dioxide in the blood in drowning: to which Dr. C. H. Kellaway replied that during resuscitation there was excessive ventilation of the lungs. Hence its administration for a brief period might be useful.

IRELAND

(FROM OUR OWN CORRESPONDENT)

THE HOSPITAL PROBLEM

THE Government of the Irish Free State sprang a surprise last week on those who are interested in the hospitals, when Dr. Ward, Parliamentary Secretary to the Minister for Local Government and Public Health, announced that no more disbursements would be made from the sweepstakes funds until the whole hospital problem of the country had been studied, and that it was the intention of the Government to appoint a commission for the purpose. The announcement was made in the course of a debate on a private Bill, introduced by Mr. T. J. Murphy, a Labour Member for a division of County Cork. The object of Mr. Murphy's Bill was to ensure that hospitals benefiting from the sweepstakes would keep at least 25 per cent. of their beds for free patients. Hospitals cannot share in the benefits unless they are able to show that in the previous year they had kept 25 per cent. of their beds free or for patients paying less than 10s. a week, but there is no power at present to ensure that they should continue to do so, and the Bill was intended to remedy that omission. According to Mr. Murphy certain hospitals were refusing treatment to patients unless they could contribute at least £2 per week. Dr. Ward agreed that there was a class of people not entitled to free treatment, but who could not afford to pay the ordinary hospital charges, and the position in that regard was not satisfactory. He was of opinion that the best possible advantage had not been taken of the opportunity afforded by the sweepstakes. The different hospitals in competition with one another developed along parallel lines, and they were not securing the highly specialised accommodation and equipment that was looked for. That and other aspects of the matter had been given a considerable amount of attention, and it was intended to introduce a Government measure calculated to secure better results out of the moneys available. He added that it was not intended to make any further disbursements until the entire situation had been examined. The new legislation, which he promised, would set up a Hospitals Commission to review the hospital situation in the area of the Irish Free State and make recommendations as to the manner and amount of the allocations to be made in the future. He suggested the postponement of Mr. Murphy's measure, and this was agreed to after the Bill had been given a second reading. In the discussion, Mr. FitzGerald-Kenney, formerly Minister for Justice, and in that capacity responsible for the control of the earlier sweepstakes, hoped that an effort would be made in the direction of amalgamation of hospitals. Such a change would lead to greater efficiency and economy. He was certain that when the hospitals were in a position to do so they would deal generously with the poor, for the hospitals and boards of management were not out to make money, but to make ends meet. He drew attention to the needs of the middle class, and he hoped that the hospitals, when they could, would make a real attempt to meet their case.

Everyone must agree with the views of the Parliamentary Secretary that the best use has not been made of the opportunities provided by the sweepstakes. As the Committee of Reference pointed out, there has been no attempt to make a survey of the needs of the community and devise a system to meet those needs, and there has been no attempt to coördinate the activities of the several institutions. It is therefore natural that a commission should be appointed to bring order out of a threatened chaos. It might have been better if the hospitals had themselves asked for such a commission, but those charged with the management of the hospitals have unfortunately shown little appreciation of the magnitude of the problem, and have been content to continue and develop their work on traditional lines. There was, indeed, a danger that the endowments received from the sweepstakes, while relieving present necessities and providing improved accommodation and equipment, might have resulted in perpetuating an outworn system.

CONTROL OF THERAPEUTIC SUBSTANCES

The Minister for Local Government and Public Health of the Irish Free State introduced to the Dáil last week a Bill to regulate the manufacture, import, and sale of therapeutic substances, its short title being the Therapeutic Substances Bill, 1932. The substances enumerated in the schedule to the Bill are vaccines, sera, toxins, antitoxins, antigens, salvarsan and analogous substances, insulin, and pituitary preparations. The Bill provides that an advisory committee shall be appointed to assist the Minister in his duties under the Act. The advisory committee is to consist of ten members, one to be appointed by the Minister for Local Government and Public Health, one by the Minister for Agriculture, and one each by the following bodies: the University of Dublin, the National University of Ireland, the Medical Registration Council, the Royal College of Physicians of Ireland, the Irish Medical Association, the Veterinary Council, the Pharmaceutical Society of Ireland, and the Institute of Chemists. The Minister may declare any therapeutic substance, the purity or potency of which cannot be adequately tested by chemical means, to be a therapeutic substance to which the Act will apply. He may make regulations as to the standards of tests to be applied to such substances. No therapeutic substance to which the Act applies may be manufactured for sale or imported for sale except under licence from the Minister. A licence to import a therapeutic substance to which the Act applies will specify the names of manufacturers from whom the applicant imports, and will only be granted on the written undertaking of the manufacturer that he will comply with the conditions prescribed by the Minister. The right of a medical practitioner to prepare a therapeutic substance with reference to the condition, and for the use, of an individual patient is safeguarded. It is certainly desirable that the substances to which the Bill applies should be under some form of control in order to ensure purity and safety, and to guard against fraud, but there is a danger that the Act may place undue restrictions in the way of rapid importation of certain substances. At the present moment few, if any, of the substances are manufactured for sale in the Irish Free State.

PLAYING FIELDS OF THE COLLEGE OF SURGEONS

On Oct. 22nd Mr. F. C. Crawley, president of the Royal College of Surgeons in Ireland, declared open the pavilion and new playing fields of the College. The fields are about two miles from the College, with convenient bus service, and are some 16 acres in extent. They have been admirably laid out, under the supervision of Mr. Alfred Miller, registrar of the College, with accommodation for football and hockey for men and women. Tennis-courts and a swimming pool are to be added. The pavilions are roomy and well-equipped. Several distinguished guests, including the Lord Mayor of Dublin, were present at the opening ceremony.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

Surg. Comdr. O. J. M. Kerrigan is placed on retd. list at his own request.

Surg. Comdr. (D) (retd.) H. M. Meek to be Surg. Capt. (D) (retd.).

Surg. Lts. G. A. Miller, T. B. Lynagh, and E. E. Malone to be Surg. Lt.-Comdrs.

The following appointments are notified: Surg. Lt.-Comdr. D. H. Kernohan to *Cambrian*, and Surg. Lt. P. M. McSwiney to *Pembroke*, for R.N.B.

ROYAL NAVAL VOLUNTEER RESERVE

Proby. Surg. Sub-Lt. G. F. Jones is confirmed in rank.

ROYAL ARMY MEDICAL CORPS

Maj.-Gen. O. L. Robinson, retd. pay, late R.A.M.C., is apptd. Col. Comdt., vice Lt.-Gen. Sir Charles H. Burtchaell, ret. pay, late R.A.M.C. (decd.).

INDIAN MEDICAL SERVICE

Lt. G. Milne to be Capt.

The probationary appts. of the undermentioned officers are confirmed. To be Lts.: E. H. Lossing, G. W. Miller, and D. G. McCaully.

ROYAL AIR FORCE

The undermentioned Flying Officers are promoted to the rank of Flight Lts.: S. C. Allen and F. F. Kennedy.

Flight Lt. C. F. Pitt relinquishes his temporary commission on completion of duty.

PANEL AND CONTRACT PRACTICE

ANNUAL PANEL CONFERENCE

THE annual conference of representatives of local medical and panel committees was held in the Great Hall of B.M.A. House on Oct. 20th, with Dr. H. C. JONAS (Barnstaple) in the chair.

Fees for Anæsthetists: Local Option

The question whether a practitioner who brings in a colleague to administer an anæsthetic should be reimbursed with the fee of that colleague has long been a matter of controversy. Following the I.A.C. model scheme, all areas provide in their distribution schemes that the fee shall be paid from the local practitioners' fund, and the amounts vary from two guineas to half a guinea, the large majority of areas paying one guinea. The opposition from various quarters has however been so strong that this year the I.A.C. decided to recommend the conference to delete this clause. Keen discussion was aroused.

Dr. G. J. B. CANDLER-HOPE (Yorks, N.R.) moved an amendment that the medical benefit consolidated regulations be altered to put the administration of anæsthetics outside the terms of medical benefit. He said that before the Act had come in, Yorkshire, anticipating that the money would come into the hands of a comparatively small number of practitioners, had decided not to admit claims for repayment of anæsthetists' fees. His committee had always contended that anæsthetics were a treatment outside the Act; under the contract the insured person was entitled to treatment from his panel doctor and not from two practitioners.

Dr. R. WARING TAYLOR (Oxon) said that in his county practitioners did this service for each other as "good pals." Formerly 100 per cent. of the claims had come from two people, and when seven years ago this had been realised, the committee had decided to have no more of it.

Dr. W. A. GREGG (London), while admitting the theoretical truth of Dr. Candler-Hope's proposition, pointed out its practical irrelevance, and the motion was lost.

Dr. A. N. FELL (Essex) then moved an amendment advocating that each panel committee should be given local option to pay or not to pay; this motion included the sense of another one by Surrey. He pointed out that in a county where men worked in partnership and staffed their own hospitals the fee might properly be paid; each panel committee could be trusted to keep its own men in order.—Dr. PETER MACDONALD (York), in support, maintained that this system would check all abuse and would leave areas like his own free to go on as they were going if they so desired.—Dr. R. L. E. DOWNER (Shropshire), discussing the suggestion that partners made most of the profit out of payment for anæsthetics, said that it was natural that partners should coöperate, and that it would be a great pity if there were not at least some advantage in having a partner. There was no reason, he said, why single-handed practitioners should not use this scheme to the full, nor why friendly colleagues—who existed in some places—should not come to a friendly arrangement to pool each other's proceeds.—Dr. A. LYNDON (Surrey) objected to the motion of the I.A.C., which he said had been carried by a majority of 3 members only in 29. Their resolution, he said, had merely voiced the London view. It would handicap the single-handed practitioner, and he hoped that the Essex amendment would succeed.

Dr. E. A. GREGG (London) complained that Essex was paying no attention to the needs of industrial areas like London, where people who had a commercially run practice exploited the scheme for what they could get out of it. He objected to having to contract out of the general arrangement that fees should be paid; committees which wanted to pay fees should, he considered, make their own domestic arrangements.—Sir HENRY BRACKENBURY (Chairman of Council) warned the conference that the I.A.C. had taken a muddled vote and that the conference should be careful to give a clear-cut vote on a clear-cut issue. The Essex proposition for local option might mean local option whether there should be any anæsthetic fee at all, or simply on what the fee should be. Did the conference wish to keep the status quo—the latter alternative—or to allow committees to abolish the fee altogether, or to fix a fee of 1s., as London had? The I.A.C. had voted for no fee at all as an alternative to fixing a fee of 1s.—i.e., reducing the fee to an absurdity.

Dr. N. W. RENTON (Kent) declared that his county had had Home Rule since 1066, when it had not surrendered, and it did not wish to be dominated by the London area. It had no clinics or hospitals to do its practitioners' work for them. A fee of 1s. would be a low form of commercialism, but a worse thing was the suggestion that one set of medical men would give anæsthetics merely in order to get a fee (A London representative: "It is true!"). It was not true in Kent, and if the profession had no means of checking the tendency within itself, Heaven help it!

Dr. A. BEAUCHAMP (Birmingham) pointed out that general practitioners wanted to keep as much work as possible in their own hands. He feared that if the motion of the I.A.C. were passed many men would send patients to hospital whom they could treat themselves. Local option would enable committees to cut out abuse; if they found that certain firms were getting too much they should cut them out—(A London representative: "How"?)—by reducing the fee to an unprofitable level.

Dr. JAMES ARTHUR (Northants), on the other hand, supported the resolution of the I.A.C. In 1928 his committee, perturbed by the large number of claims, had reduced the fee to half a guinea for gas and a guinea for other anæsthetics. The result had been a reduction in the total value but not in the number of claims. The figures on analysis had proved somewhat similar to those of London: single-handed practitioners had made only about 8 per cent. and more than half the claims had come from a small group of partnerships. Remonstrance had only increased the number of claims, and the committee had, therefore, this year asked for the deletion of the clause. It intended to proceed as it had for emergency treatment—by the friendly method of each practitioner helping his colleagues at need.

Dr. C. H. PANTING (Essex) wished to keep the option in the hands of the local committee, as he considered that it was very dangerous for committees to surrender power or responsibility. The anæsthetic fee only represented 0·6 per cent. of the whole of the pool; to abolish the fee would not be beneficial to the patient, and the committees could deal with exploitation by close scrutiny and, when they saw fit, by refusal to pay.

After Dr. S. P. HUGGINS (Bucks) had testified to how well his county got on without any claims, and Dr. FELL had emphasised that his motion was intended to empower a committee to refuse a fee, the Essex amendment was passed by a very considerable majority.

The Essex proposal for local option then came before the conference as a substantive motion, and an amendment was moved by Dr. Renton (Kent) to refer the matter back to the I.A.C.—Dr. Dain, however, vigorously opposed a reference back without a definite direction from the conference, and the amendment was withdrawn.—A motion by Dr. J. O. Summerhayes (East Sussex) to adhere to the status quo was defeated after strong opposition had been expressed by Dr. Gregg (London), whose committee object strongly to sitting in judgment on their colleagues in questions of treatment, and by Dr. P. Macdonald (York), who supported the Essex motion and pointed out how it would help London.—The conference was not even moved by the warning of Sir H. Brackenbury and Dr. L. J. Picton (Cheshire) that such a decision would make the Essex proposal mandatory on the I.A.C.—The principle of local option was then carried by a very large majority.

An Attractive Pension Scheme

Dr. Dain reminded the conference that it had often expressed the desire for a pension scheme for panel practitioners, and that as a result of a resolution passed by it in the previous year the I.A.C. had consulted persons familiar with group insurances and with the needs of medical men, and were now able to put forward a scheme which offered a series of benefits especially suitable to men in insurance practice. Exceptionally favourable terms had been obtained by limiting participation to three companies which had made the most acceptable offer. Their proposals were identical and the opportunities of enrolling members would be divided equally between them, but members would have free choice. Dr. Dain then moved a series of motions against invoking the assistance of the Government, against compulsory deductions from the quarterly cheques for premiums, and against monopoly by any one company.

Dr. Gregg (London) opposed the first motion on the ground that the time might come when the I.A.C., in bargaining with the Government, might find it very useful to accept a pension scheme instead of, for instance, an increase of 6*d.* in the capitation fee which the Government were unwilling to grant; the conference, however, agreed to the motion and also to the second proposition.—Dr. W. G. Thwaites (Brighton) feared that three companies might constitute a monopoly almost as considerable as one, but Dr. Dain pointed out that the companies concerned could only offer the present exceptionally generous terms if they were protected from further competition, and Dr. Thwaites withdrew the Brighton objection.

In reply to a question by Sir H. Brackenbury, Dr. Dain explained further that the I.A.C. had originally asked seven firms to tender, and that the other four had replied that they were not prepared to do this kind of business. A fourth company had offered to participate at a much later stage, but in fairness to the original three it had been excluded. He explained a few of the principal advantages of the scheme.[1] A medical examination would not, he said, be required in the ordinary way, but only for exceptional reasons. The chairman urged that the conference should not merely agree to the adoption of the policy by insurance practitioners, but that every member should vote. The conference thereupon adopted it, only one hand being raised in dissent

The Defence Trust

Mr. N. Bishop Harman (treasurer) announced that 71 per cent. of the quota (£250,000) had been subscribed, and in good-humoured but vigorous language praised the committees which had subscribed all or nearly all their contribution and criticised the laggards and disaffected.—Dr. Dain, in corroboration, sympathised with committees which frankly considered the trust useless, and promised to undertake persuasive measures, but strongly condemned areas which continued to profit by everything which the organisation offered, such as membership of the conference and electoral franchise, but would give nothing in return. He hoped, he said, to give reasons next year why each individual committee had refused to subscribe, and Dr. A. E. Larking (Hastings) expressed the view that refusal was generally due, not to any lack of public spirit, but simply to ignorance of the purposes for which the money was collected.

After the conference had adopted the report and accounts of the trust, Dr. Dain emphasised the importance of keeping the fund a live one and of not merely stopping when the first quota had been subscribed. He therefore moved that committees which had completed their quota should be asked to send further contributions in respect of those practitioners who had contributed for less than ten years, so that each would have contributed for that period.

Dr. J. E. Bates (Surrey) moved that committees that had completed their quota should not be asked to contribute further. He explained that as a private individual he disagreed entirely with this amendment, but that it had been carried through the Surrey committee by the overwhelming vote of the younger members.

Dr. T. S. Laird (Lanarkshire), however, agreed with Surrey's amendment. His committee, he said, had been one of the earliest to pay its full quota; it felt that those who had failed to contribute were being dealt with far too mildly. The I.A.C. would be surprised at the amount of money the local committees would put up if they really believed it was needed, but until the laggards came into line Lanarkshire would not send another penny.—Nevertheless, the Surrey amendment was defeated and the motion carried by a large majority.

The question of the ways in which the fund should be applied aroused considerable discussion. Dr. J. H. Cardale (London) moved that the profession should consider its policy concerning the future of the trust and define the purpose to which the funds should be applied.—Dr. Dain replied that he had been preaching for several years the importance of taking a big view of the fund, and of making it live and useful to members. A quarter of a million would be no use in a fight, but it was a nest-egg from which to start. In the case of real need he believed that Lanarkshire was right and that an unexpectedly large amount of money would be available, but it was necessary to enlarge the fund at the disposal of the trust and to spend its interest in wise and useful ways. The trustees could not accept dictation from any other body on the disposal of the fund, for they were responsible to deal with the money under the terms of the trust, but the voice of the panel committees would naturally be heard and might be paramount in the work. He suggested a reference to the trustees, who would issue a statement of policy in the coming year; and the London representative agreed.

It was not easy to understand the motives underlying the present views of the conference on the spending of the interest. It rejected the modest suggestion of the I.A.C. to spend £150 a year on lectures to medical students concerning their future duties as panel practitioners, although Dr. Dain and others pointed out the advantages of being able to employ locum tenents who would at any rate know the elements of panel prescribing and the keeping of panel records and would not be a continual source of anxiety. On the other hand, it agreed to the proposal of the I.A.C. to try for a year the policy of assisting the retirement of aged and infirm practitioners of very straitened means against whose work a complaint had been made.

---

[1] See The Lancet, Sept. 3rd, p. 537.

It considered, however, that the fund might suitably be employed to anticipate the extension by the State of the national health medical service for dependents. East Sussex, in the person of Dr. SUMMERHAYES, moved a resolution that the I.A.C., in collaboration with the B.M.A., should urge and assist in the effective development of coördinated public medical and similar services, where necessary by means of loans from the trust income, and report progress to the next conference. Dr. Summerhayes told the conference that the motion had originated with Dr. R. Fothergill. The profession, he thought, should be in a position to oppose any State scheme to which it objected, and it could only do so if it already had an alternative in full working order. The difficulties were apathy, lack of time, lack of money, and lack of experience; if the I.A.C. and the B.M.A. appointed a subcommittee to conduct the scheme, these objections would be met. The scheme should be linked up with all others in existence. In this way the family doctor, who alone knew the patients, would be in full and continuous charge of them. There was still time for the profession to protect itself, but if the State were to move to-morrow, the profession would be "in the soup."

Sir HENRY BRACKENBURY outlined the work of the B.M.A., with which he said the matter chiefly rested. He suggested that the motion did not fully state the reasons for this important movement, and suggested a change in the wording:—

> "That, in order that the medical profession may be in a better position to assist in the formulation at the appropriate time of a satisfactory scheme for the extension of the National Health Service for the dependents of insured persons and others of like economic status, the trustees of the National Insurance Defence Trust be requested to collaborate with the British Medical Association in assisting the effective development of public medical services."

The policy of the I.A.C. was, he said, the extension of an insurance scheme to dependents. These services were not being set up to combat that policy, but in order to meet the immediate requirements of the people concerned and as a means of gaining experience and of ascertaining the features which ought to be embodied in a national scheme. This resolution was adopted by the conference without further discussion.

Other Business

The chairman of the conference was elected its representative on the new conjoint committee of Epsom College.

The conference agreed with acclamation to a motion by Warrington that no further deductions from the capitation fee should be accepted, and that the fee of 9*s.* should be restored as soon as circumstances permit. Dundee moved that no extension of range of service should be accepted without increased remuneration, but the conference shared Dr. Dain's view that a general practitioner must do the best for his patients whether they were private or insured, and the motion was withdrawn.

CORRESPONDENCE

THE POLICY OF SCHOOL-CLOSURE

To the Editor of THE LANCET

SIR,—In your leading article (last week, p. 903) on the closing of Stowe you rightly give first place to the interests of the community in general, while admitting that the school was most concerned with the particular interests of its boys. I should like you to know, however, that the school was by no means indifferent to the interests of the community. The memorandum which I sent to all parents on the dispersal of the school contained the following passage:—

> "The dispersal of the school may seem to involve some danger to the community. But this will not be so if two conditions are fulfilled: (1) that every boy shall be kept away from intimate contact with other young people for three weeks from the day he leaves here; (2) that the local medical officer of health shall be informed at once of the boy's arrival in his area.
>
> "I earnestly hope that these two conditions will be loyally observed."

In addition a letter from the school medical officer to the home doctor was sent to every household.

The collection of information about any cases of poliomyelitis which may occur in houses to which Stowe boys have returned this month should not be a difficult task, and I fully realise its importance. We shall be happy to cooperate in any inquiries which the Ministry may wish to set on foot.

It should be remembered by our medical critics that even in the interests of the community no school can forcibly retain its boys if their parents wish to remove them.

I am, Sir, yours faithfully,

J. F. ROXBURGH,
Headmaster.

Stowe, Buckingham, Oct. 24th, 1932.

⁂ The Ministry of Health have now given the needed guidance. In a circular dated Oct. 24th, it is stated that the Ministry have received certain inquiries as to the wisdom or expediency of closing residential schools in which isolated cases of poliomyelitis may have occurred. "The Ministry," it says, "are definitely of the opinion that the balance of advantage is in favour of *not* closing a residential school in which poliomyelitis has appeared. If the school be closed any potential infectiousness of the disease is more widely distributed, and passes beyond such means of supervision and control as are furnished in a well-equipped residential school conducted on hygienic lines."—ED. L.

INSULIN AND THE B.P., 1932

To the Editor of THE LANCET

SIR,—The authorities responsible for the British Pharmacopœia, 1932, have made it far from easy for the dispensing chemists to fill prescriptions for insulin. If the prescription reads "Insulin B.P. 100 units. Half a cubic centimetre to be injected twice daily," the chemist has no difficulty; he must supply one of the many brands of insulin containing a preservative. Should the prescription, however, read "Insulin

B.P. 100 units. To be used as directed," he seems to be at liberty to supply the cheapest insulin, even if it does not happen to have any preservative added. The reason he may do this is the fact that there is no indication in the prescription that the dose is not 100 units. The B.P. reads (p. 232):—

> "If it is distributed into sealed ampoules, each of which contains one dose only, an antiseptic need not be added."
>
> "The containers are either sealed glass ampoules, each of which contains an amount intended to be used as one dose, or glass phials, each containing a larger volume and sealed so as to allow the withdrawal of successive doses on different occasions."
>
> "Doses: By subcutaneous injection. 5 to 100 Units."

The word "sealed" is used when the container is closed with a rubber cap, and therefore need not mean that the ampoule must be made entirely of glass. Again, insulin in solution according to the B.P. must be such "that the solution contains 20 Units per millilitre," and therefore a prescription for insulin containing 40 units or 80 units per millilitre cannot be filled with a preparation included in the B.P.

The question arises as to the circumstances which led the Pharmacopœia Commission to insist upon preservative being added to the solution when packed economically. I imagine that the Therapeutic Substances Act influenced it to some extent. That Act reads:—

> "When any therapeutic substance is issued in liquid form in containers which are sealed in such a manner that portions of the contents can be withdrawn for use on different occasions the liquid shall contain a sufficient proportion of some antiseptic to prevent growth of any organism which may be accidentally introduced in the process of removing a portion of the contents of the container."

The Act was to put into force a finding of a Commission appointed to inquire into a disaster caused by pathogenic micro-organisms growing in a bottle of antitoxic serum. Lawyers assert that legislation for "hard luck" cases results in bad law. Perhaps rules designed to prevent disaster following carelessness may do more harm than good; they may save a life or two and damage many. As far as insulin is concerned the substitution of the word "antiseptic" by the word "substance" would allow insulin to be supplied without antiseptic because the acid in the solution prevents the growth of organisms. The alteration would not benefit patients suffering from Addison's disease, Addison's anæmia, diabetes insipidus, tetany, &c.; the extracts which are necessary for them would still have to contain antiseptic if packed economically. We have no evidence that preservatives do not destroy the active principles in these extracts, and it may take years to obtain evidence.

It seems extraordinary that a State which prohibits preservatives being added to food should insist on preservatives being added to therapeutic substances for injection when packed economically. Drs. W. W. Payne and A. G. Signy showed that insulin in solution with a pH 4·0 not only prevented the multiplication of *Bacillus coli* and *Staphylococcus aureus* but actually destroyed them. It had been asserted that when insulin became a medium in which micro-organisms could grow, it became cloudy owing to precipitation of the insulin upon the pH being raised, and therefore if patients were advised to use insulin only when water-clear, there would be no risk of their injecting a suspension of micro-organisms.

Dr. P. Hartley investigated the conditions upon which a solution might be rendered a culture medium for staphylococci. He added 920 freshly grown and presumably vigorous cocci, suspended in 25 cubic millilitres of broth, to 5 c.cm. insulin, to which he added varying quantities of alkali. It might have been a more convincing experiment if he had used a suspension in distilled water and not contaminated the insulin with peptones, even in small quantities. He found that if alkali was added to alter the pH from 4 to 8·3 the solution might become clear and allow cocci to grow for a time. The solution would pass through a cloudy stage if the alkali were added in successive doses.

Now that the majority of diabetic patients keep their syringes in spirit and do not boil them in water, the possibility of introducing alkali is removed. Since more than a million units of insulin in solution without added antiseptics are used daily in Europe, obviously the opinion that the addition of antiseptic should be added is far from universal. Some members of the staffs of many hospital take the view that the risk of infection from not adding antiseptic is smaller than the risk of damaging the patient by injecting antiseptic, and therefore, at a very large number of institutions, solutions of insulin are used which cannot be described as Insulin B.P. Amongst these are Guy's, Great Ormond-street, the London Hospital, and Middlesex Hospital. This does not seem a commendable state of affairs.

I am, Sir, yours faithfully,

O. LEYTON.

Portland-place, W., Oct. 23rd, 1932.

PROFESSIONAL SECRECY

To the Editor of THE LANCET

SIR,—It is unfortunate that, when the question of professional secrecy arises, there is often some charge against a medical man or it is claimed that evidence is being withheld which is essential for the administration of justice. The issue consequently becomes confused; and it appears as if secrecy is to the advantage of medical men, whereas it is entirely to the advantage of the patient; and the medical profession is concerned because, unless secrecy is safeguarded, the practice of medicine becomes increasingly difficult. It is the custom of judges in some local courts to demand the production of insurance cards kept for panel patients when an application is made for compensation. Protests by medical men have been made from time to time, but these have been overruled. Unless the card is produced the claim of the applicant is rejected. The dangers will be appreciated from the following case:—

A miner, a widower aged 48, had a fracture of the left femur in 1927. This had united with two inches shortening and an ankylosed knee. He was paid partial compensation and worked as an ostler underground until this year. The pain became worse and he stopped work. His claim for full compensation was refused by the company and the case was taken to court. The point at issue was whether it was fair to ask such a man to walk 1000 yards underground. I appeared for the applicant. The applicant's doctor when giving evidence had to produce the insurance card, which was handed to the respondent's solicitor. It was then revealed that this man had contracted gonorrhœa two years previously. The whole history was then gone into. Though the doctor and myself were quite definite that this man was cured and that the condition of the left leg had nothing to do with gonorrhœa, it did not in any way prevent a very active cross-examination as to its relationship to gonorrhœal rheumatism, in which the judge himself participated. The respondent's doctor admitted that he did not consider the state of the left leg had anything to do with gonorrhœa. The question of venereal disease had been raised by the solicitor merely to damage the character of the applicant in the eyes of the judge and to obscure the issue. This miner's application was before the court merely because he had worked in a dangerous occupation and had suffered the effect of the danger. As a result an incident in his life was revealed in open court in front of many people from his district and, I believe, a grown-up son and daughter.

In the solicitors' room afterwards contempt was expressed for this solicitor, for the judge who had allowed such an abuse to occur, and for the medical profession who have made no effort to safeguard their patients; for this practice has been going on in the courts for a number of years. As a result patients will no longer consult medical men about venereal disease and will prefer to remain untreated. In addition, that confidence between a medical man and his patients which is so essential can no longer exist when information is so easily revealed.

The profession should not be content to let matters drift. The protests that have been raised amount to no more than a gesture, and our failure to make a stand for medical privileges has damaged our prestige.

I am, Sir, yours faithfully,

Cardiff, Oct. 15th, 1932. T. E. HAMMOND.

CONSTIPATION WITH INCONTINENCE

To the Editor of THE LANCET

SIR,—I was much interested to read in this week's issue of THE LANCET (p. 927) an abstract of a paper by C. E. Bloch, of Copenhagen, describing this condition of constipation with incontinence of fæces occurring in children. It seems probable that now this syndrome has been observed and reported similar cases will be published in this country. In the summer of this year a surgical colleague of mine at the Derbyshire Hospital for Sick Children, Mr. H. A. Lavelle, passed on to the medical ward for treatment a girl of 11 who had all the characteristic clinical features described by Bloch. She had been referred to hospital for incontinence of fæces (unaccompanied by urine) of gradual onset and increasing frequency; incontinence had been present for several months, and on admission she was passing, several times a day and completely uncontrolled, a motion that was normal in colour and consistence. Discipline and disgust at home had resulted in such shame and timidity as to suggest to the house surgeon the appearance of a mental defect. The anal sphincter was relaxed, and immediately after defæcation the rectum was still filled.

The girl showed some clinical findings not referred to in your abstract. The abdominal musculature was strikingly thin, and scybalous masses could be felt stretching across the abdomen like a string of large oval beads. She was given charcoal by mouth, and we were astonished to find it appearing at the anus within 18 hours. The condition was obviously one of retention with overflow, the overflow consisting for the most part of fresh daily residue which had managed to slip past the obstructing scybalous masses. At first she was treated with simple enemata; these were soon discovered to be useless and it required several days of colonic lavage before the whole colon was cleared. Each day the removal of a few inches of fæces could be made out by abdominal palpation. Then with the help of abdominal exercises and a stimulating aperient (aloes and nux vomica), she resumed a daily habit of defæcation and with its resumption she became a normal and happy child.

This treatment appears to be more rapid and more rational than that outlined by Bloch, and this fact—together with the rarity of the condition and the small additions to the clinical picture which we were able to make—has prompted me to send you this account. I am, Sir, yours faithfully,

Derby, Oct. 21st, 1932. DOUGLAS HUBBLE.

HUMAN AND BOVINE TUBERCULOSIS

To the Editor of THE LANCET

SIR,—In his presidential address to the Hunterian Society reported in your last issue (p. 900) Dr. Nathan Raw propounds some interesting queries on the subject of tuberculosis which probably can only be answered by clinical results and not by laboratory methods. A few conclusions I have arrived at are these. In the first place I have never failed to find the carrier in all private cases and likewise in many dispensary cases. The carrier is invariably the nurse which in most instances is the mother who may have been infected by the father, and in no case has milk even been suspected. One of my little boys acquired the infection from a nurse whilst I acquired it from dispensary patients. In both instances removal from the source completed the cure. Tuberculosis in children under 12 whether glandular, pulmonary, or abdominal is best treated by bovine tuberculin (P.T.O.), Koch's old tuberculin being practically useless. Patients over 12 receive benefit from the latter form of tuberculin whilst P.T.O. is of no use. These results lead one to the belief that the bovine type of tubercle bacillus finds young tissue a suitable soil whilst the human type lives only on older tissues. This seems feasible as cows rarely live more than 12 years. Though the bovine type is only (with certain exceptions) found in children, good results can be obtained to the children by treating the carrier or carriers with the human type of tuberculin. It is an everyday experience to find several types of tuberculosis in a tuberculous family of brothers and sisters.

I am, Sir, yours faithfully,

Buxton, Oct. 24th, 1932. R. CRAWSHAW HOLT.

SUBCUTANEOUS RUPTURE OF THE POPLITEAL ARTERY

To the Editor of THE LANCET

SIR,—Two cases of rupture of the popliteal artery are recorded by Mr. C. P. G. Wakeley and Mr. W. Ogilvy Reid in THE LANCET of Oct. 15th (p. 829); in each case the rupture was due to an injury, the lesion was just below the opening in the adductor magnus, and amputation of the thigh was performed within 30 hours of the accident. They could find a record of only four similar cases since the war, but were convinced that the condition was "not so rare as the number of recorded cases would lead one to expect." It may be of interest, therefore, to give a brief account of a case of perforation of the artery in the neighbourhood of the foramen in the adductor magnus, in which the onset and progress of the symptoms were much more gradual, and ligature of the artery instead of amputation was resorted to.

The patient, a man of about 70, was knocked down by a cyclist on June 4th, 1918. On the 18th he complained of a painful swelling in the right thigh over Scarpa's triangle, for which he consulted Dr. G. J. Conford, of Felixstowe, to whom I am indebted for notes of the case. Dr. Conford looked upon it at first as phlebitis. By the 26th the swelling in the thigh had considerably increased, was fairly hard and fixed, with slight but definite pulsation perceptible on palpation. I saw him in consultation on this day, and considered it to be a rapidly growing sarcoma, for which I advised immediate amputation. During the next few days the swelling of the thigh increased very rapidly, accompanied by severe pain, and he decided to submit to operation on July 2nd, a fortnight after the symptoms were first noticed.

At the operation the limb was found to be very greatly swollen and cyanic, and it was evident that there must have been very considerable hæmorrhage into the tissues. Instead of proceeding to amputation as was originally proposed, an incision was made over the femoral artery. Much clot was removed, and the artery tied at the apex of Scarpa's triangle. The incision was prolonged downwards along Hunter's canal, masses of clot being cleared away, and the artery followed to the foramen in the adductor magnus where a circular perforation about 5 mm. in diameter was found. The artery, which was atheromatous and calcareous in places, was ligatured above and below the perforation and the wound closed. The vein was not interfered with. The patient made an uninterrupted recovery, and was walking about within a few weeks. He died about five years later from pulmonary disease.

I am, Sir, yours faithfully,
HERBERT H. BROWN, F.R.C.S.
Ipswich, Oct. 21st, 1932.

PROTEOLYTIC FERMENT IN AMŒBIC DYSENTERY

To the Editor of THE LANCET

SIR,—In an annotation on the early differential diagnosis between amœbic and bacillary dysentery in your issue of Oct. 15th (p. 853) mention is made of the secretion of a proteolytic ferment in *E. histolytica*, suggested by J. Anderson in 1921 and again by A. Alexieff in the present year. There are to my mind weighty reasons—phylogenetic, systematic, and biological—for doubting that amœbæ give off such a ferment. The sole instance among the protozoa in which digestive ferments are known to be passed out of the body is in the case of the suctorial acinetaria, where (as is always the case) they are secreted by the nucleus, which has finger-like extensions prolonged towards the tentacles. In no entamœba is there any suggestion of extracellular digestion, and the secretion of a proteolytic ferment implies far too great a phylogenetic jump. Even in the intracellular sporozoa there is no evidence of any "external" secretion of digestive ferments. In the malarial parasites, for instance, the resident product of digestion, the pigment is formed only in the cytoplasm of the parasite, never in the more or less used-up red corpuscle.

It must be remembered that the ectoplasm of *E. histolytica* is peculiarly well developed, tough, and mobile. When the penetration, by mobility of relatively delicate things like the germs of coccidia actually into the epithelial cells of the intestine is considered, there is no difficulty about the ectoplasmic pseudopodia of *histolytica* being able to bore or scrape a way inwards. Phylogenetically the extracellular secretion of digestive ferments undoubtedly began in the flagellates where at the base of the stomodæum the endoplasm is for a small area uncovered by the delicate investing cuticle. The different type of histolysis occurring in an amœbic ulcer from that to be seen in the submucosa in bacillary dysentery is probably explainable by the invasion of ordinary intestinal bacteria, which are more or less swept away in heavy infection with dysenteric bacilli.—I am, Sir, yours faithfully,

Walton-on-Thames, Oct. 19th. H. M. WOODCOCK.

RESPIRATORY EFFICIENCY TESTS

To the Editor of THE LANCET

SIR,—In his article of Sept. 24th (p. 665) and letter of Oct. 15th (p. 869) on tests for respiratory function, Dr. Alan Moncrieff attributes the first spirometric experiments to John Hutchinson (1846). Actually, Charles Thackrah, in his book on Industrial Diseases (I will not give its full title which contains 38 words), published in 1831, describes "an apparatus which may be termed a pulmometer," about which he adds:

> "This is a large graduated jar, inserted over and filled with water. The person blows through a tube, the lower end of which is under the jar—making, however, but one expiration at each trial. . . . This mode, it will be observed, does not show the mere capacity of the lungs. The result of the experiment is the compound of the capacity of the air cells and the power of the respiratory muscles."

This apparatus Thackrah used very extensively, not only on workers in dusty trades, but also on such people as clerks in offices and fashionable ladies in tight stays, and suggested it might be of value in assessing recruits for the army, and used among his normals, "19 individuals from the 14th Light Dragoons," including apparently four members of the band.

I have been unable to determine whether Thackrah originated the idea, but his extensive and painstaking observations deserve precedence over those of Hutchinson, to whom is attributed the invention of the spirometer even in such a work as Garrison's History of Medicine.

I am, Sir, yours faithfully,
F. F. HELLIER.
The Medical School, Leeds, Oct. 24th, 1932.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED OCT. 15TH, 1932

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 12 (last week 17); scarlet fever, 2078; diphtheria, 1007; enteric fever, 83; acute pneumonia (primary or influenzal), 833; puerperal fever, 28; puerperal pyrexia, 102; cerebro-spinal fever, 30; acute poliomyelitis, 36; acute polio-encephalitis, 4; encephalitis lethargica, 8; continued fever, 1 (Hampstead); dysentery, 21; ophthalmia neonatorum, 78. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on Oct. 18th–19th was as follows:—Small-pox, 49 under treatment, 0 under observation (last week 44 and 4 respectively); scarlet fever 1764; diphtheria, 1657; enteric fever, 21; measles, 230; whooping-cough, 311; puerperal fever, 24 (plus 8 babies); encephalitis lethargica, 231; poliomyelitis, 6; "other diseases," 161. At St. Margaret's Hospital there were 21 babies (plus 9 mothers) with ophthalmia neonatorum.

Deaths.—In 117 great towns, including London, there was no death from small-pox, 3 (1) from enteric fever, 12 (1) from measles, 5 (3) from scarlet fever, 10 (2) from whooping-cough, 21 (6) from diphtheria, 72 (19) from diarrhœa and enteritis under two years, and 46 (10) from influenza. The figures in parentheses are those for London itself.

Of the deaths from diarrhœa, 6 were reported from Birmingham, 5 from Leeds, 4 each from Gateshead and West Bromwich. Liverpool, Newcastle-on-Tyne, and Wigan each reported 2 deaths from measles. Diphtheria was responsible for 3 deaths at Dewsbury.

The number of stillbirths notified during the week was 276 (corresponding to a rate of 45 per 1000 total births), including 46 in London.

HOSPITAL NEEDS OF SHANGHAI.—The report for 1931 of the Lester Chinese Hospital at Shanghai records the transfer to a new building made possible by a legacy of one million taels from Mr. Henry Lester, a prominent British resident. During the year there were nearly 51,000 out-patients who made over 133,000 attendances. The report points out some of the serious hospital needs of Shanghai.

LONDON MEDICAL EXHIBITION

The exhibition held in the New Hall of the Horticultural Society from Oct. 17th to 21st was one of the largest that has been seen, and testified, it is to be hoped, to a revival of trade. The following account is not exhaustive, but picks out for comment only the more novel products and apparatus from the very large and interesting selection put before the visitors.

Drugs and Pharmaceutical Preparations

(90) Allen and Hanburys, Ltd. (Bethnal Green, E.), showed "Kapsol" halibut-liver oil in 3-minim capsules; and Calcium Lactobionate, for use in place of the less soluble gluconate, in ampoules.—(35) Allnatt and Partners (296, Regent-street, W.) showed "Octozone," a form of oxygen with powerful oxidising and antiseptic properties, for rheumatism and other conditions; and also a portable lithotomy support which folds into a small case.—(14) Anglo-American Pharmaceutical Co., Ltd. (59, Dingwall-road, Croydon), introduced for the first time in this country "Casali-Alpha," a colloidal ferment containing gold, platinum, and palladium, for the correction of premature senility and low metabolism.—(7) Armour and Co., Ltd. (St. Martin's-le-Grand, E.C.), have added to their long list of Glanoid preparations "Ferroglanoid," a combination of liver with iron, and were displaying their new preparation of thyroid in accordance with the 1932 Pharmacopœia.—(44) Bayer Products, Ltd. (19, St. Dunstan's-hill, E.C.), drew special attention to "Serules," containing sera under pressure and sealed with a rubber valve and needle in a sterilised glass tube—a companion to the well-known "Venules."—(13) The Bio-Chemical Laboratories, Ltd. (94, Clerkenwell-road, E.C.), drew attention to "Paraphakin," a preparation to be taken internally for arresting senile cataract.—(37) Boots Pure Drug Co., Ltd. (Nottingham), on their blue and silver stand, showed charts illustrating the uses of "Amyl-Meta-Cresol," an antiseptic supplied in capsules; of "Pepsac," a desiccated stomach powder for use in cases of pernicious anæmia; and the activity of their vitamin D preparation, "Vitamalt"; also their compound preparation of liver and iron, "Livron," of which good clinical results are reported.—(61) British Alkaloids, Ltd. (Winchester House, E.C.), drew attention to their T.C.P.B. 3, a colloidal emulsion of their antiseptic, for gastro-intestinal troubles.—(140) The British Drug Houses, Ltd. (Graham-street, City-road, N.), exhibited crystals of pure vitamin D, as used in "Radiostol" solution and pellets; also a new concentrate of vitamin A of an activity equivalent to 50,000 blue units. Their preparation "Avoleum" is a simple solution of this concentrate in oil, and possesses an activity of 900.—(114) Burroughs Wellcome and Co. (Snow Hill Buildings, E.C.) drew attention to their tabloid "Diginutin" and their "Stipolac" tetraiodophenolphthalein in two tubes, one containing the salt and the other the acid mixture; the freshly precipitated substance is obtained by mixing the two compounds, and is claimed to obviate nausea. (1) G. W. Carnrick and Co. (232-240, Vauxhall Bridge-road, S.W.) had on view a preparation of liver extract for intramuscular injection, "Erythgen"; and also a new ovarian follicular hormone, "Thelestrin," each ampoule containing 25 Allen-Doisy rat units.—(63) Chesebrough Manufacturing Co. (Cons.) (Victoria-road, Willesden, N.W.) have taken over "Listerine," in addition to their well-known "Vaseline Capsicum" and "Pineoleum." The last they now market in a cheaper bottle with a nasal pipette in the cork.—(4) Continental Laboratories, Ltd. (30, Marsham-street, S.W.), have added to their well-known "Taxol" and "Lactobyl" a new mistletoe preparation for hypertension, "Detensyl."—(117, 118, 138) Crookes' Laboratories, British Colloids, Ltd. (Park Royal, N.W.), drew attention to "Collosol" halibut-liver oil, which they claim to be the only natural preparation of this oil, entirely free from all solvents and ergosterol; also "Karvol," an antiseptic for the upper respiratory tract, which is active in the presence of serum.—(140, 150, 160) Evans Sons Lescher and Webb, Ltd. (56, Hanover-street, Liverpool), showed "Hepatex I-M," a liver extract for intramuscular injection. They also displayed "E.D.P.," a bismuth formic-iodide dusting powder for skin conditions.—(70) Fassett and Johnson, Ltd. (St. John's Gate Buildings, 86, Clerkenwell-road, E.C.), had on view anti-rheumatic seaweed salts for use in the bath at home. They also pointed out that they now supply "Eatan" in an orange-flavoured jelly, each cube containing a full dose.—(11) Genatosan, Ltd. (Loughborough, Leicestershire), selected from among their well-known products, "Sanatogen," "Genasprin," and vaccines, a nasal spray of anti-catarrh vaccine as a preventive of colds.—(95, 96, 109) Glaxo Laboratories (56, Osnaburgh-street, N.W.) drew special attention to their "Adexolin" vitamin capsules, and to an anti-virus preparation which can be applied externally.—(121) C. J. Hewlett and Son, Ltd. (35–42, Charlotte-street, E.C.), showed their useful General Practitioner's, Midwifery, and Surgeon's bags, and also Baron's portable lithotomy support. Their many pharmaceutical preparations, particularly *Pil. digitalis pur.*, were on show. They also showed trusses and appliances in their capacity as makers to the City of London Truss Society.—(71) The Hoffmann-la Roche Chemical Works, Ltd. (The "Roche" Laboratories, 51, Bowes-road, N.), exhibited "Ovobrol," a new compound of their well-known "Sedobrol" sedative with bromide; and "Prostigmin," an intestinal stimulant for use after operations.—(45) Howards and Sons, Ltd. (Ilford), had a charming little green and white replica of an old-fashioned chemist's shop, in which they showed their many preparations, particularly "Quinisan," a new quinine salt, and "Agotan" for rheumatism.—(122) Johnson and Sons, Ltd. (Hendon Way, Hendon, N.W.), showed "Arvitin," a silver preparation; lysol guaranteed to contain 50 per cent. cresols; and "Elixir Casc. Aromat.," a palatable preparation.—(137) J. F. Macfarlan and Co. (32, Bethnal Green-road, London, E.) picked out, from among their anæsthetic agents, "Brisettes," capsules containing 20 mins. of chloroform for use in childbirth.—(99) May and Baker, Ltd. (Battersea, S.W.), exhibited among their preparations "Estriol," a preparation of 40 per cent. iodine in an ester of poppy-seed oil for the radiography of small cavities.—(103) H. R. Napp, Ltd. (3–4, Clement's-inn, W.C.), drew special attention to their "Xorox"; their bromide preparation, "Multibral"; their "Raminal," for anæmia and debility; and also their "Glucator," a simple apparatus for rapid and accurate estimation of sugar in the urine.—(42) National Drug Industries, Ltd. (Emmott-street, E.), the makers of "Petrolax," showed "Peldo," a protective ointment which is proving valuable in cases of industrial dermatitis.—(39) Paines and Byrne, Ltd. (31, Southampton-street, W.), had on view a gland preparation in capsule form for cases of dysmenorrhœa, "Pabryn-a-menotab."—(64) Parke, Davis and Co. (50–54, Beak-street, W.) featured "Haliverol," a preparation of oil of halibut fortified with "Viosterol," an irradiated ergosterol; this oil, they claim, is 60 times as potent in vitamin A as cod-liver oil, and 250 times in vitamin D; they also exhibited "Antuitrin-S," a solution of follicle-stimulating and luteinising hormone of the anterior pituitary.—(57) Pearson's Antiseptic Co., Ltd. (61, Mark-lane, E.C.), in addition to "Iodine-Medol" and Creolin, showed standardised lysol at half the price of the ordinary preparation.—(75) Petrolagar Laboratories, Ltd. (Braydon-road, N.), pointed out that their "Petrolagar" was now cheaper, and their "Neobovinine" pleasanter to the taste.—(46) The

into the tissues. Instead of proceeding to amputation as was originally proposed, an incision was made over the femoral artery. Much clot was removed, and the artery tied at the apex of Scarpa's triangle. The incision was prolonged downwards along Hunter's canal, masses of clot being cleared away, and the artery followed to the foramen in the adductor magnus where a circular perforation about 5 mm. in diameter was found. The artery, which was atheromatous and calcareous in places, was ligatured above and below the perforation and the wound closed. The vein was not interfered with. The patient made an uninterrupted recovery, and was walking about within a few weeks. He died about five years later from pulmonary disease.

I am, Sir, yours faithfully,
HERBERT H. BROWN, F.R.C.S.
Ipswich, Oct. 21st, 1932.

PROTEOLYTIC FERMENT IN AMŒBIC DYSENTERY

To the Editor of THE LANCET

SIR,—In an annotation on the early differential diagnosis between amœbic and bacillary dysentery in your issue of Oct. 15th (p. 853) mention is made of the secretion of a proteolytic ferment in *E. histolytica*, suggested by J. Anderson in 1921 and again by A. Alexieff in the present year. There are to my mind weighty reasons—phylogenetic, systematic, and biological—for doubting that amœbæ give off such a ferment. The sole instance among the protozoa in which digestive ferments are known to be passed out of the body is in the case of the suctorial acinetaria, where (as is always the case) they are secreted by the nucleus, which has finger-like extensions prolonged towards the tentacles. In no entamœba is there any suggestion of extracellular digestion, and the secretion of a proteolytic ferment implies far too great a phylogenetic jump. Even in the intracellular sporozoa there is no evidence of any "external" secretion of digestive ferments. In the malarial parasites, for instance, the resident product of digestion, the pigment is formed only in the cytoplasm of the parasite, never in the more or less used-up red corpuscle.

It must be remembered that the ectoplasm of *E. histolytica* is peculiarly well developed, tough, and mobile. When the penetration, by mobility of relatively delicate things like the germs of coccidia actually into the epithelial cells of the intestine is considered, there is no difficulty about the ectoplasmic pseudopodia of *histolytica* being able to bore or scrape a way inwards. Phylogenetically the extracellular secretion of digestive ferments undoubtedly began in the flagellates where at the base of the stomodæum the endoplasm is for a small area uncovered by the delicate investing cuticle. The different type of histolysis occurring in an amœbic ulcer from that to be seen in the submucosa in bacillary dysentery is probably explainable by the invasion of ordinary intestinal bacteria, which are more or less swept away in heavy infection with dysenteric bacilli.—I am, Sir, yours faithfully,

Walton-on-Thames, Oct. 19th. H. M. WOODCOCK.

RESPIRATORY EFFICIENCY TESTS

To the Editor of THE LANCET

SIR,—In his article of Sept. 24th (p. 665) and letter of Oct. 15th (p. 869) on tests for respiratory function, Dr. Alan Moncrieff attributes the first spirometric experiments to John Hutchinson (1846). Actually, Charles Thackrah, in his book on Industrial Diseases (I will not give its full title which contains 38 words), published in 1831, describes "an apparatus which may be termed a pulmometer," about which he adds:

> "This is a large graduated jar, inserted over and filled with water. The person blows through a tube, the lower end of which is under the jar—making, however, but one expiration at each trial. . . . This mode, it will be observed, does not show the mere capacity of the lungs. The result of the experiment is the compound of the capacity of the air cells and the power of the respiratory muscles."

This apparatus Thackrah used very extensively, not only on workers in dusty trades, but also on such people as clerks in offices and fashionable ladies in tight stays, and suggested it might be of value in assessing recruits for the army, and used among his normals, "19 individuals from the 14th Light Dragoons," including apparently four members of the band.

I have been unable to determine whether Thackrah originated the idea, but his extensive and painstaking observations deserve precedence over those of Hutchinson, to whom is attributed the invention of the spirometer even in such a work as Garrison's History of Medicine.

I am, Sir, yours faithfully,
F. F. HELLIER.
The Medical School, Leeds, Oct. 24th, 1932.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED OCT. 15TH, 1932

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 12 (last week 17); scarlet fever, 2078; diphtheria, 1007; enteric fever, 83; acute pneumonia (primary or influenzal), 833; puerperal fever, 28; puerperal pyrexia, 102; cerebro-spinal fever, 30; acute poliomyelitis, 36; acute polio-encephalitis, 4; encephalitis lethargica, 8; continued fever, 1 (Hampstead); dysentery, 21; ophthalmia neonatorum, 78. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on Oct. 18th–19th was as follows:—Small-pox, 49 under treatment, 0 under observation (last week 44 and 4 respectively); scarlet fever 1764; diphtheria, 1657; enteric fever, 21; measles, 230; whooping-cough, 311; puerperal fever, 24 (plus 8 babies); encephalitis lethargica, 231; poliomyelitis, 6; "other diseases," 161. At St. Margaret's Hospital there were 21 babies (plus 9 mothers) with ophthalmia neonatorum.

Deaths.—In 117 great towns, including London, there was no death from small-pox, 3 (1) from enteric fever, 12 (1) from measles, 5 (3) from scarlet fever, 10 (2) from whooping-cough, 21 (6) from diphtheria, 72 (19) from diarrhœa and enteritis under two years, and 46 (10) from influenza. The figures in parentheses are those for London itself.

Of the deaths from diarrhœa, 6 were reported from Birmingham, 5 from Leeds, 4 each from Gateshead and West Bromwich. Liverpool, Newcastle-on-Tyne, and Wigan each reported 2 deaths from measles. Diphtheria was responsible for 3 deaths at Dewsbury.

The number of stillbirths notified during the week was 276 (corresponding to a rate of 45 per 1000 total births), including 46 in London.

HOSPITAL NEEDS OF SHANGHAI.—The report for 1931 of the Lester Chinese Hospital at Shanghai records the transfer to a new building made possible by a legacy of one million taels from Mr. Henry Lester, a prominent British resident. During the year there were nearly 54,000 out-patients who made over 133,000 attendances. The report points out some of the serious hospital needs of Shanghai.

LONDON MEDICAL EXHIBITION

The exhibition held in the New Hall of the Horticultural Society from Oct. 17th to 21st was one of the largest that has been seen, and testified, it is to be hoped, to a revival of trade. The following account is not exhaustive, but picks out for comment only the more novel products and apparatus from the very large and interesting selection put before the visitors.

Drugs and Pharmaceutical Preparations

(90) Allen and Hanburys, Ltd. (Bethnal Green, E.), showed "Kapsol" halibut-liver oil in 3-minim capsules; and Calcium Lactobionate, for use in place of the less soluble gluconate, in ampoules.—(35) Allnatt and Partners (296, Regent-street, W.) showed "Octozone," a form of oxygen with powerful oxidising and antiseptic properties, for rheumatism and other conditions; and also a portable lithotomy support which folds into a small case.—(14) Anglo-American Pharmaceutical Co., Ltd. (59, Dingwall-road, Croydon), introduced for the first time in this country "Casali-Alpha," a colloidal ferment containing gold, platinum, and palladium, for the correction of premature senility and low metabolism.—(7) Armour and Co., Ltd. (St. Martin's-le-Grand, E.C.), have added to their long list of Glanoid preparations "Ferroglanoid," a combination of liver with iron, and were displaying their new preparation of thyroid in accordance with the 1932 Pharmacopœia.—(44) Bayer Products, Ltd. (19, St. Dunstan's-hill, E.C.), drew special attention to "Serules," containing sera under pressure and sealed with a rubber valve and needle in a sterilised glass tube—a companion to the well-known "Venules."—(13) The Bio-Chemical Laboratories, Ltd. (94, Clerkenwell-road, E.C.), drew attention to "Paraphakin," a preparation to be taken internally for arresting senile cataract.—(37) Boots Pure Drug Co., Ltd. (Nottingham), on their blue and silver stand, showed charts illustrating the uses of "Amyl-Meta-Cresol," an antiseptic supplied in capsules; of "Pepsac," a desiccated stomach powder for use in cases of pernicious anæmia; and the activity of their vitamin D preparation, "Vitamalt"; also their compound preparation of liver and iron, "Livron," of which good clinical results are reported.—(61) British Alkaloids, Ltd. (Winchester House, E.C.), drew attention to their T.C.P.B. 3, a colloidal emulsion of their antiseptic, for gastro-intestinal troubles.—(140) The British Drug Houses, Ltd. (Graham-street, City-road, N.), exhibited crystals of pure vitamin D, as used in "Radiostol" solution and pellets; also a new concentrate of vitamin A of an activity equivalent to 50,000 blue units. Their preparation "Avoleum" is a simple solution of this concentrate in oil, and possesses an activity of 900.—(114) Burroughs Wellcome and Co. (Snow Hill Buildings, E.C.) drew attention to their tabloid "Diginutin" and their "Stipolac" tetraiodophenolphthalein in two tubes, one containing the salt and the other the acid mixture; the freshly precipitated substance is obtained by mixing the two compounds, and is claimed to obviate nausea. (1) G. W. Carnrick and Co. (232-240, Vauxhall Bridge-road, S.W.) had on view a preparation of liver extract for intramuscular injection, "Erythgen"; and also a new ovarian follicular hormone, "Thelestrin," each ampoule containing 25 Allen-Doisy rat units.—(63) Chesebrough Manufacturing Co. (Cons.) (Victoria-road, Willesden, N.W.) have taken over "Listerine," in addition to their well-known "Vaseline Capsicum" and "Pineoleum." The last they now market in a cheaper bottle with a nasal pipette in the cork.—(4) Continental Laboratories, Ltd. (30, Marsham-street, S.W.), have added to their well-known "Taxol" and "Lactobyl" a new mistletoe preparation for hypertension, "Detensyl."—(117, 118, 138) Crookes' Laboratories, British Colloids, Ltd. (Park Royal, N.W.), drew attention to "Collosol" halibut-liver oil, which they claim to be the only natural preparation of this oil, entirely free from all solvents and ergosterol; also "Karvol," an antiseptic for the upper respiratory tract, which is active in the presence of serum.—(140, 150, 160) Evans Sons Lescher and Webb, Ltd. (56, Hanover-street, Liverpool), showed "Hepatex I-M," a liver extract for intramuscular injection. They also displayed "E.D.P.," a bismuth formic-iodide dusting powder for skin conditions.—(70) Fassett and Johnson, Ltd. (St. John's Gate Buildings, 86, Clerkenwell-road, E.C.), had on view anti-rheumatic seaweed salts for use in the bath at home. They also pointed out that they now supply "Eatan" in an orange-flavoured jelly, each cube containing a full dose.—(11) Genatosan, Ltd. (Loughborough, Leicestershire), selected from among their well-known products, "Sanatogen," "Genasprin," and vaccines, a nasal spray of anti-catarrh vaccine as a preventive of colds.—(95, 96, 109) Glaxo Laboratories (56, Osnaburgh-street, N.W.) drew special attention to their "Adexolin" vitamin capsules, and to an anti-virus preparation which can be applied externally.—(121) C. J. Hewlett and Son, Ltd. (35–42, Charlotte-street, E.C.), showed their useful General Practitioner's, Midwifery, and Surgeon's bags, and also Baron's portable lithotomy support. Their many pharmaceutical preparations, particularly *Pil. digitalis pur.*, were on show. They also showed trusses and appliances in their capacity as makers to the City of London Truss Society.—(71) The Hoffmann-La Roche Chemical Works, Ltd. (The "Roche" Laboratories, 51, Bowes-road, N.), exhibited "Ovobrol," a new compound of their well-known "Sedobrol" sedative with bromide; and "Prostigmin," an intestinal stimulant for use after operations.—(45) Howards and Sons, Ltd. (Ilford), had a charming little green and white replica of an old-fashioned chemist's shop, in which they showed their many preparations, particularly "Quinisan," a new quinine salt, and "Agotan" for rheumatism.—(122) Johnson and Sons, Ltd. (Hendon Way, Hendon, N.W.), showed "Arvitin," a silver preparation; lysol guaranteed to contain 50 per cent. cresols; and "Elixir Casc. Aromat.," a palatable preparation.—(137) J. F. Macfarlan and Co. (32, Bethnal Green-road, London, E.) picked out, from among their anæsthetic agents, "Brisettes," capsules containing 20 mins. of chloroform for use in childbirth.—(99) May and Baker, Ltd. (Battersea, S.W.), exhibited among their preparations "Estriol," a preparation of 40 per cent. iodine in an ester of poppy-seed oil for the radiography of small cavities.—(103) H. R. Napp, Ltd. (3–4, Clement's-inn, W.C.), drew special attention to their "Xorox"; their bromide preparation, "Multibral"; their "Raminal," for anæmia and debility; and also their "Glucator," a simple apparatus for rapid and accurate estimation of sugar in the urine.—(42) National Drug Industries, Ltd. (Emmott-street, E.), the makers of "Petrolax," showed "Peldo," a protective ointment which is proving valuable in cases of industrial dermatitis.—(39) Paines and Byrne, Ltd. (31, Southampton-street, W.), had on view a gland preparation in capsule form for cases of dysmenorrhœa, "Pabryn-a-menotab."—(64) Parke, Davis and Co. (50–54, Beak-street, W.) featured "Haliverol," a preparation of oil of halibut fortified with "Viosterol," an irradiated ergosterol; this oil, they claim, is 60 times as potent in vitamin A as cod-liver oil, and 250 times in vitamin D; they also exhibited "Antuitrin-S," a solution of follicle-stimulating and luteinising hormone of the anterior pituitary.—(57) Pearson's Antiseptic Co., Ltd. (61, Mark-lane, E.C.), in addition to "Iodine-Medol" and Creolin, showed standardised lysol at half the price of the ordinary preparation.—(75) Petrolagar Laboratories, Ltd. (Braydon-road, N.), pointed out that their "Petrolagar" was now cheaper, and their "Neobovinine" pleasanter to the taste.—(46) The

Pharmaceutical Corporation, Ltd. (39–40, Aldersgate-street, E.C.), drew attention to "Novaseptic," a powerful germicide containing the bacterial ingredients (quinotoxins and benzoic acid) of their well-known "Novutox" local anæsthetic.—(155) Reed and Carnrick (94, Clerkenwell-road, E.C.) showed their enteric-coated "Thyracoids," containing iodothyroglobulin. They claim that these are the only physiologically standardised thyroid.—(58) Research Products, Ltd. (12–13, Henrietta-street, W.C.), demonstrated mineral vitamin tablets containing copper, iron, iodine, and yeast; and also "Pyrolactin," a standardised and filtered milk for intramuscular injection, with or without vaccines.—(147) Sandoz Chemical Works (5, Wigmore-street, W.), in addition to their well-known preparations, showed "Partagon Bougies," providing a compound of colloidal silver chloride and sodium silver chloride formed in an aqueous medium, for the treatment of venereal disease.—(27, 28) Savory and Moore, Ltd. (143, New Bond-street, W.), among their wide range of preparations, showed "Urotropal," a urinary antiseptic, especially for diseases arising from excess of uric acid; "Laxaloids"—glandular extracts with agar-agar; and "Laxarol," a paraffin emulsion with agar-agar, phenolphthalein, and carminatives.—(47) Schering, Ltd. (3, Lloyds-avenue, E.C.), gave prominence at their stand to their most recent products: "Progynon," for secondary amenorrhœa and climacteric disturbances; "Neotropin," a urinary antiseptic for oral use; "Solganal," gold products and Uroselectan B.—(146) Sharp and Dohme, Ltd. (252, Regent-street, W.), exhibited their "Solution S.T. 37," a new antiseptic of low surface tension, for which they claim exceptional penetration; also a concentrated preparation of Felton's serum for lobar pneumonia.—(125) E. H. Spicer and Co., Ltd. (Endocrines, Ltd., Watford), introduced "Haliver Oil" with ergosterol, a halibut oil with a high percentage of vitamins A and D, manufactured in Montreal.—(85) Vitamins, Ltd. (23, Upper Mall, W.), had on view "Bemax" chocolate, which has been considerably improved in taste. This attractive sweetmeat contains 20 per cent. of "Bemax," and therefore a large proportion of vitamin B.—(10) White's Laboratories, Ltd. (Bush House, W.C.), illustrated cinematographically their method of preparing a tested and standardised preparation of the non-saponifiable fraction of cod-liver oil, which is dispensed in tablets flavoured with oil of wintergreen.

Surgical Instruments and Appliances

(26) Bruce, Green and Co., Ltd. (14–18, Bloomsbury-street, W.C.), directed attention to a new ophthalmological trial frame mounted on a bracket, with full range of adjustment.—(3) Cameron's Surgical Specialities, Ltd. (40, Langham-street, W.), have made their well-known diagnostic sets more durable.—(6) J. and A. Carters, Ltd. (125–129, Great Portland-street, W.), showed an improved dry bed for incontinent patients.—(145) Clement Clarke, Ltd. (16, Wigmore-street, W.), showed their "Synoptophore," a new and accurately calibrated apparatus for curing all degrees of squint.—(141) Stanley Cox, Ltd. (39, Gerrard-street, W.), had on view the "Autogram" portable X ray set, complete with 2½ kw. "Metalix" tube for operation at 70 kv., with a maximum current of 10 ma. It has complete range of adjustment.—(30) C. W. Dixey and Son, Ltd. (19, Old Bond-street, W.), showed a new British slit-lamp apparatus at a price much below that of the cheapest continental lamps.—(18) Theodore Hamblin, Ltd. (15, Wigmore-street, Cavendish-square, W.), had on view a full range of reading glasses; and "Spotlight" spectacles: a small focusing lamp fixed to the bridge of the spectacle frame.—(33) T. Hawksley, Ltd. (351, Oxford-street, W.), among their extremely long range of appliances for the deaf, displayed the new model of the Marconi Otophone, which amplifies by the ordinary wireless methods, giving an exceptionally loud reproduction for very deaf subjects.—(2) Holborn Surgical Instrument Co., Ltd. (26, Thavies-inn, Holborn Circus, E.C.), in addition to their instruments, drew attention to "Armour-plate" unbreakable glass for tables and shelves.—(110) The Inhaling Drug and Apparatus Co., Ltd. (87, Eccleston-square, S.W.), drew attention to their British-made "Apneu" Collison inhaler, an improved and simplified form of their original Spiess-Dräger inhalation apparatus.—(142) C. Davis Keeler (47, Wigmore-street, W.) drew special attention to the "Decagon," which they claim is the only automatic refraction unit in existence. It gives an automatic reading of the points of refraction error. It is British made, and provides a quick and entirely new and convenient method of diagnosing and measuring astigmatism.—(156) Medical Surgical Sundries, Ltd. (97, Swinderby-road, Wembley), exhibited their "Esseff" inhaling apparatus; also an oiled-canvas first-aid wallet in a red metal cylinder, for the car.—(24) W. H. Pettifor (11, Victoria-street, S.W.), among his various aids for the deaf, showed a hearing-tube with a stethoscope microphone which is placed over the speaker's trachea while the earpiece goes in the deaf person's ear; the sound is amplified, while at the same time the speaker's lips are left perfectly visible.—(86) Radium Electric, Ltd. (24, Grosvenor-gardens, S.W.), exhibited their "Q-Ray" Electro-Radium-Compress. These pads are now obtainable in different radio-active strengths up to 0·092 mg. radium element.—(23) Rayner and Keeler, Ltd. (100, New Bond-street, W.), showed a transparent protractor in the form of a roller blind for rapidly and accurately transferring the boundaries of a scotoma from the Bjerrum screen to a chart.—(12) W. J. Rendell, Ltd. (161–165, Rosebery-avenue, E.C.), by means of an analytical quartz lamp, showed the perfect distribution of quinine throughout their pessaries.—(62) A. G. Sheldon and Co., Ltd. (59, Weymouth-street, W.), have added to their useful range of drums an assortment of sterilised dressings done up in cardboard cartons and costing only 2*s*. 6*d*. and 1*s*. 6*d*.—(157) Sparklets, Ltd. (London, N.18), showed a resuscitator for the administration of carbon dioxide, oxygen, or both; Sparklet bulbs are inserted into a light metal holder, and each bulb gives six minutes' supply of gas at an optimim rate of 2 litres per minute. They also showed an apparatus for producing solid carbon dioxide.—(101) The Surgical Manufacturing Co., Ltd. (83–85, Mortimer-street, W.), emphasised a smaller and cheaper sphygmomanometer, and a diagnostic set which can be connected to the main supply.—(16) The Wilson Rubber Co., Ltd. (85, Buckingham-avenue, Slough, Bucks), has been formed to meet the demand for British-made rubber gloves. It was founded under the supervision of the American Wilson Rubber Co., the largest manufacturers of rubber gloves in the world, and is now importing highly skilled workmen to turn out the gloves and employing British potters to make the forms on which the gloves are stretched. It makes a specialty of gloves for hands which have lost fingers.

Books and Periodicals

(21, 22) Baillière, Tindall and Cox (7–8, Henrietta-street, Covent Garden, W.C.), among other important works, had on view Strümpell's "Practice of Medicine" (thirtieth German edition). and Lipscomb's "Diseases of Old Age."—(20) William Heinemann (Medical Books), Ltd. (99, Great Russell-street, W.C.), exhibited their latest works on medicine and surgery, including L. S. T. Burrell's "Artificial Pneumothorax," A. Cannon and E. D. T. Hayes' "Principles and Practice of Psychiatry," also T. H. van de Velde's trilogy of books on sex life.—(32, 40, 41) H. K. Lewis and Co., Ltd. (136 and 140, Gower-street, W.C.), showed the office equipment of a consulting-room, including a roll-top cabinet for panel records; a series of hand-painted coats of arms; also the

"Bedford Doll," a full-sized female figure for training nurses. Among their medical books were Martindale and Westcott's "The Extra Pharmacopœia (20th edition, brought up to date to conform with the 1932 Pharmacopœia), and H. Bailey and R. J. M. Love's "A Short Practice of Surgery."—(25) OXFORD UNIVERSITY PRESS (Warwick-square, E.C.) pointed out particularly V. Meisen's "Varicose Veins and Hæmorrhoids"; Sicard and Forestier's "Lipiodol"; von Economo's "Encephalitis Lethargica"; Nattrass's "Commoner Nervous Diseases"; and the fourth edition of Harrison's "Diagnosis and Treatment of Veneral Diseases."—(76) "THE MEDICAL PRESS AND CIRCULAR" (8, Henrietta-street, W.C.) showed interesting relics of their long history, including the first volume of the Amalgamated Journal published in Dublin in 1886.—(29) "THE PRACTITIONER" (6-8, Bouverie-street, E.C.) displayed recent special numbers, including that on common ailments, and drew attention to future issues, which will contain symposia on influenza, diseases of ear, nose, and throat, and mental disease.—(98) JOHN WRIGHT AND SONS, LTD. (Bristol), had on view a number of books and periodicals, including "Cancer of the Lung," by Maurice Davidson: "Emergency Surgery," by Bailey; "Chronic Otorrhœa," by Friel; and the "Synopsis" series.

Foods and Drinks

(100) CADBURY BROS., LTD. (Bournville, Birmingham), dispensed "Bourn-Vita," their new food drink, composed of British malt, eggs, milk, and cocoa, with a high content of vitamins A, B, and D. —(144) CORN PRODUCTS CO., LTD. (Bush House, W.C.), showed "Dextrosol Brand," a very pure form of dextrose, conforming with the requirements of the 1932 Pharmacopœia, and also "Karo Syrup," an infant food containing a mixture of sugars in which the first difficult step in the digestive process has been accomplished so that no one type of fermentation prevails, and digestion and absorption proceed simultaneously.—(77) COW AND GATE, LTD. (Cow and Gate House, Guildford), showed their well-known preparations, and introduced "Caprolac," the only British preparation of goat's milk, for babies who are sensitive to cow's milk.—(115) ENERGEN FOODS CO., LTD. (Willesden, N.W.), invited visitors to taste their jams and marmalade for diabetic patients.—(73) OXO, LTD. (Thames House, Queen Street-place, E.C.), in addition to their well-known food and gland preparations, had on view a liver substance for injection in the critical stages of pernicious anæmia.—(126, 130) TRUFOOD, LTD. (Wrenbury, Cheshire), had a large stand to remind visitors of the value of their humanised and full-cream dried milk and "Secway" whey powder.

Miscellaneous

(60) BATH. A representative of Bath explained the new thermal vapour treatment now available at the Spa.—(9) THE GAS LIGHT AND COKE CO. (Horseferry-road, S.W.) had on view a new model gas fire raised from the ground and let into the wall, called the "Sun-Square" fire, and a gas infra-red treatment lamp. Their gas stoves are now made in six colours.—(143) JOHNSON AND JOHNSON (Slough, Bucks) emphasised the value of their "Tek" toothbrush.—(72) THE NATIONAL OPHTHALMIC TREATMENT BOARD (1, High-street, Marylebone, W.) presented their system of providing ophthalmic service at a very low inclusive charge, which has now been reduced.

Finally, at one of the most interesting stands in the show (17), INDEX, LTD. (Thames House, Millbank, S.W.), demonstrated an admirable and ingenious card-index system. The records are built up unit by unit, and an inexpensive cabinet may be purchased for a start. All the names are visible as soon as the drawer is pulled out, and the cards can be written on without removal from the file.

LONDON MEDICAL SOCIETIES

AT the opening of a new session we are again giving for the convenience of our readers the names of presidents and hon. secretaries of London medical societies, with the addresses at which they can be approached.

Royal Society of Medicine.—President: Mr. V. Warren Low, F.R.C.S.; Hon. Secretaries: Dr. George Riddoch and Mr. C. W. Gordon-Bryan, F.R.C.S. Address: 1, Wimpole-street, W.1.

Royal Society of Tropical Medicine and Hygiene.—President: Dr. G. Carmichael Low; Hon. Secretaries: Dr. C. M. Wenyon and Dr. N. Hamilton Fairley. Address: Manson House, 26, Portland-place, W.1.

Medical Society of London.—President: Sir John Broadbent, F.R.C.P.; Hon. Secretaries: Dr. T. Jenner Hoskin and Mr. Neil Sinclair, F.R.C.S. Address: 11, Chandos-street, W.1.

Hunterian Society.—President: Dr. Nathan Raw; Hon. Secretaries: Mr. Andrew McAllister, F.R.C.S., and Mr. M. H. Oldershaw, F.R.C.S. Address: 26, Upper Wimpole-street, W.1.

Harveian Society.—President: Mr. Cecil P. G. Wakeley, F.R.C.S.; Hon. Secretaries: Dr. R. Cove-Smith and Prof. Tom Hare. Address: 2, Burwood-place, W.2.

Medico-Legal Society.—President: Lord Riddell; Hon. Secretaries: Mr. Ernest Goddard and Dr. W. G. Barnard. Address: 3, South-square, Gray's Inn, London, W.C.1.

London Association of the Medical Women's Federation.—President: Prof. Mary Lucas Keene, M.B.; Hon. Secretary: Dr. Annis Gillie. Address: 86, Porchester-terrace, W.2.

West London Medico-Chirurgical Society.—President: Dr. H. H. Mills; Hon. Secretaries: Dr. W. S. C. Copeman and Mr. G. B. Woodd-Walker, F.R.C.S. Address: 15, Harley-street, W.1.

Chelsea Clinical Society.—President: Mr. Ivor Back, F.R.C.S.; Hon. Secretaries: Mr. A. Rugg-Gunn, F.R.C.S., and Mr. H. P. Bayliss, L.D.S. Address: 49, Harley-street, W.1.

West Kent Medico-Chirurgical Society.—President: Dr. Harold Pritchard; Hon. Secretary: Dr. C. J. B. Buchan. Address: 267, Baring-road, S.E.12.

Royal Medico-Psychological Association.—President: Dr. R. B. Campbell; Hon. General Secretary, Dr. Reginald Worth. Secretary's office: 11, Chandos-street, W.1.

Society of Medical Officers of Health.—President: Dr. G. H. Pearce; Hon. Secretary: Mr. G. L. C. Elliston. Address: 1, Upper Montague-street, Russell-square, W.C.1.

Tuberculosis Association.—President: Dr. Jane Walker; Hon. Secretary: Dr. G. T. Hebert. Address: St. Thomas's Hospital.

Paddington Medical Society.—President: Dr. G. de Swietochowski; Hon. Secretary: Dr. A. Baldie. Address: 7, Warwick-gardens, W.2.

South-West London Medical Society.—President: Dr. H. C. Sturdy; Hon. Secretaries: Dr. E. G. Housden and Dr. A. W. Wells. Address: 51, Longley-road, S.W.17.

Medical Society of Individual Psychology.—Chairman: Prof. W. Langdon Brown; Hon. Secretary: Dr. F. G. Crookshank. Address: 57A, Wimpole-street, W.1.

British Institute of Radiology.—President: Prof. F. L. Hopwood; Hon. Secretaries: Dr. W. M. Levitt and Mr. G. E. Bell. Address: 32, Welbeck-street, W.1.

St. John's Hospital Dermatological Society.—President: Dr. J. M. H. MacLeod; Hon. Secretary: Dr. J. M. Spencer Scovell. Address: 49, Leicester-square, W.C.2.

Society for the Study of Inebriety.—President: Lady Barrett, M.S.; Hon. Secretary: Dr. T. N. Kelynack. Address: 19, Park-crescent, Portland-place, London, W.1.

MEDICAL NEWS

University of Oxford

Exeter College.—Mr. John Carew Eccles, D.Phil., formerly junior research Fellow, has been elected to a senior research Fellowship in medicine. This is the first appointment to the Fellowship, which is entitled the Staines Fellowship, and was founded by the late Amelia Jackson in memory of her father.

University of Cambridge

On Oct. 21st the following degrees were conferred:—

M.D.—*F. H. McCay, *E. A. H. Grylls, and T. S. Goodwin.

M.B. & B. Chir.—*F. H. King, *R. B. Pringle, *J. H. Bentley, W. McO. Macgregor, V. T. Thorne, C. S. Lewis, W. McN. Niblock, and C. E. Taylor.

M.B.—*E. B. Murrell, B. C. Nicholson, R. A. Jones, and D. J. R. Steen.

B.Chir.—*J. L. S. Scott, *Matthew Westwood, and W. W. Sargant.

* By proxy.

Dr. A. N. Drury has been appointed Huddersfield lecturer in special pathology.

Mr. Geoffrey Keynes, assistant surgeon to St. Bartholomew's Hospital, has been appointed to the Sandars readership in bibliography for 1933.

Royal College of Surgeons of Edinburgh

At a recent meeting of the College, with Mr. John Wheeler Dowden, the president, in the chair, the following 29 successful candidates (out of 97 entered) who passed the requisite examinations between July 7th and 15th were admitted as Fellows:—

Deborah M. Alcock, M.B. Edin.; N. J. Bakhru, M.B. Bomb.; W. S. Brindle, M.B. Liverp.; J. H. Casewell, M.B. Cape Town; C. G. Crawford, M.B. Sydney; Robert Everett, M.B. Edin; J. A. C. Fleming, M.B. Edin.; Isabella Forshall, M.B. Lond.; Isaac Goldberg, M.B. Edin.; J. I. R. Gray, M.B. N.Z.; T. E. Holland, M.D. Manitoba; R. McK. Honey, M.B. Edin.; J. J. Jennings, M.B. Irel.; Phyllis I. Kaufmann, M.B. Manch.; Herbert Kaye, M.R.C.S. Eng.; Kenneth Knowles, M.R.C.S. Eng.; R. B. Lumsden, M.B. Edin.; H. I. McClure, M.B. Belfast; H. M. Martin, M.B. Dub.; C. F. Mayne, M.R.C.S. Eng.; J. J. O'Reilly, M.B. Dub.; R. J. Parry, M.B. Lond.; C. O. F. Rieger, M.B. Adelaide; Eugene Sandner, M.B. Melb.; D. P. Settna, M.R.C.S. Eng.; L. A. H. Snowball, M.B. Lond.; J. S. Sutherland, M.B. Edin.; Ba Than, M.B. Calcutta; and G. E. Waterworth, M.D. N.Z.

Scottish Conjoint Board

At recent examinations by the conjoint board of the Royal Colleges of Physicians and Surgeons of Edinburgh and the Royal Faculty of Physicians and Surgeons of Glasgow, the following candidates were successful:—

L.R.C.P., L.R.C.S., & L.R.F.P. & S.

M. D. S. Jayawardana, K. W. Harcourt, D. McN. Beaugie, A. McN. Aitken, A. B. Morrison, R. D. Johnston, R. L. Sutton, V. T. Naidu, Donald Cameron, S. D. Senapathi, T. D. L. Bolan, Andrew Muir, M. G. Naidoo, Julius Ossip, Alastair Macdonald, M. A. Abdalla, and G. R. Tissoveresinghe.

D.P.H.

D. M. Alston, Elizabeth R. Jamieson, Jessie M. Jamieson, J. L. Hunter, John Comrie, Jessie R. Wilson, and A. St. J. Moffat.

Part. I.—T. K. Kuruvila, Henry Caplan, R. A. Read, Barbara C. Welsh, A. C. Scott, Jean W. R. Paton, Rachel B. Nelson, M. D. Macqueen, W. M. P. McDonald, and J. L. Smith.

Part II.—J. F. Hamilton.

Royal College of Physicians of Ireland

At the annual stated meeting of the College, held on St. Luke's Day, Dr. Thomas Gillman Moorhead, Regius professor of physic in the University of Dublin, was re-elected president for a third year of office. He nominated Dr. F. C. Purser vice-president. The censors appointed were: In medicine, Drs. F. C. Purser and C. Murphy; in medical jurisprudence, Dr. E. T. Freeman; in midwifery, Dr. J. S. Quin. In the evening the President and Fellows dined in the College Hall, and entertained, among other guests, the Lord Mayor of Dublin, the President of the Royal College of Surgeons in Ireland, the President of University College, Dublin, the Bishop of Limerick, and the Dean of the School of Physic.

Royal Opening of Hospital Extensions

On Monday last week Prince George opened a new casualty department at King Edward Memorial Hospital, Ealing, of which he is patron. The cost has been £10,000. Two days later he opened an extension of the Royal Victoria and West Hants Hospital at Boscombe upon which £120,000 has been expended, of which £87,000 has been obtained. The additions, which have more than doubled the size of the hospital, include new out-patients' blocks, extensive improvements of the specialist departments, and a large number of wards for private patients. The board room has been entirely decorated and furnished as a memorial to the late Colonel Heygate Vernon, F.R.C.S., who rendered great services to the hospital.

National Association for the Prevention of Tuberculosis

The verbatim report of the annual conference held in London in July last has now been published. Copies may be had from the secretary, N.A.P.T., Tavistock House North, Tavistock-square, London, W.C.1, price 7*s.* 6*d.*, post free.

Royal Institution

The first of the Friday evening discourses, delivered at 9 P.M., will be given on Nov. 18th by Dr. R. G. Canti, who will demonstrate a film showing the cultivation of living tissue cells. At 5.15 P.M. on Tuesdays, from Nov. 1st to 22nd, Prof. E. N. da C. Andrade will speak on Rays and Radiation, and at the same hour on Nov. 29th and Dec. 6th and 13th, Prof. Lancelot Hogben is to lecture on Colour Changes in the Animal Kingdom. The 107th course of six lectures "adapted to a juvenile auditory" will be given by Prof. A. O. Rankine, beginning on Dec. 27th. The address of the Royal Institution is 21, Albemarle-street, London, W.1.

An International Congress on Biliary Lithiasis.

This Congress was held at Vichy from Sept. 19th to Sept. 24th, when delegates attended from Germany, Cuba, Spain, Japan, United States, Nicaragua, Venezuela, Argentine, Austria, Belgium, Bolivia, Brazil, Bulgaria, Canada, Chile, Ecuador, Egypt, Greece, Guatemala, Holland, Hungary, Iceland, Italy, Mexico, Norway, Peru, Portugal, Poland, Roumania, Sweden, Switzerland, Turkey, Uruguay, and Great Britain. The principal papers read were on (1) The Sequelæ of Cholecystectomy; (2) The Medical Hydrotherapeutic Treatment of Biliary Lithiasis; and (3) The Lithiasistic Liver.

Prof. D. P. D. Wilkie, of Edinburgh, reviewed the subject of cholecystectomy. The type with remote effects of chronic cholecystitis, he said, were either thin people with myocardial lesions due to toxins from the gall-bladder or very fat females with similar toxic effects in a fat-laden heart; the former gave good results, but the latter only if medical treatment was given for the obesity. In this type he included cases of rheumatism and nephritis, which had improved by cholecystectomy.—Dr. Victor Donnet (New York) pointed out that cholecystectomy should not be performed unless medical treatment failed and the gall-bladder function grossly impaired because of the dyspepsia which followed the passive dilatation of the whole of the biliary system.—Dr. A. Gosset and Dr. Petit-Dutaillis (Paris) mentioned jaundice due to obstruction of the common bile duct by calculi left at the operation, stenosis of the duct, adhesions causing extensive compression.—Dr. C. Giraud (Montpellier) stated that many of the sequelæ were due to a residue of the liver disturbances present before the operation which react to medical treatment only after operation.—Dr. H. Béclère (Paris) showed the value of X ray diagnosis in revealing post-operative fistula, calculi, in the biliary system or by combined radiography of stomach and duodenum, sequelæ due to kinking of the duodenal cap.—Dr. P. Abrami mentioned the experimental work on ionic antisepsis moving the pH of bile to the alkaline side, and thus rendering it unsuitable for many bacteria. He also mentioned the value of urotropine intravenous injections in association with medical drainage.—Prof. F. Umber (Berlin) stressed the effect on the liver cells of biliary obstruction producing a picture like subacute yellow atrophy (hepatosis), and the value of glycogen to the liver cell, and suggested a diet rich in lævulose and glucose, with insulin injections in association with biliary antisepsis and hydrotherapy.—Dr. L. Delherm and Dr. H. Dausset (Paris) showed that true hepatic stones contained less cholesterol than the gall-bladder stones, and felt that both occurred in people with a calculous diathesis.—Dr. M. Brulé (Paris) mentioned the obstructive jaundice of hepatitis and its differentiation from common duct obstruction by the marked enlargement of the liver in the second case; of the differential diagnosis of jaundice due to cancer and stone in the common duct. He pointed out that in the latter bile can be obtained by duodenal drainage.—Dr. J. Dieryck (Louvain) considered the only reliable liver function test depended upon a measure of the glycogenic function, for which purpose he used galactose and measured the total and partial concentrations in the urine, differentiating jaundice due to obstruction of the bile ducts from that due to hepatic cellular disease.—Dr. R. Gilbert (Geneva) mentioned the value of tetraiodophenolphthalein by the mouth in radiography, especially in association with X ray examination of the stomach and duodenum, and suggested its possible value as a liver function test. The proceedings of the Congress, with abstracts of papers in six languages, have been issued in volume form. (Paris: G. Doin et Cie. Fr.50.)

Sir Henry Dale, M.D., secretary of the Royal Society and director of the National Institute of Medical Research, has been elected a member of the Swedish Academy of Science.

World League for Sexual Reform

On Thursday, Nov. 3rd, at 8 P.M., at the London School of Hygiene, Keppel-street, London, W.C., the British section of this league will hold a meeting to discuss the Laws concerning Abortion.

National Institute for the Blind

Mr. C. C. G. Nock and Mr. John May, the first blind candidates to sit for the Society of Apothecaries' examination in diathermy, have successfully qualified in that subject. Both are chartered masseurs, having been trained at the National Institute's school.

Royal Sanitary Institute

A discussion on Modern Ideas on the Construction and Administration of Infectious Diseases Hospitals will be opened by Dr. J. A. Charles, at the Town Hall, Durham, at 4 P.M. on Friday, Nov. 4th. At the house of the Institute, 90, Buckingham Palace-road, London, S.W., at 5.30 P.M., on Tuesday, Nov. 8th, there will be discussions on the Cyanide Fumigation of Ships and on the Control of Insects on Foodstuffs and other Raw Materials by Fumigation. At 5.30 P.M. on Tuesday, Nov. 29th, also at the Institute, Dr. James Fenton will open a discussion on Clearance Areas and Improvement Areas.

Chelsea Clinical Society

The annual dinner of this society was held at Claridge's Hotel on Oct. 18th and was attended by 95 members and guests. Mr. Ivor Back took the chair and replied to the toast of the Chelsea Clinical Society, proposed in a humorous speech by Mr. Sidney Dark. "The Guests" was proposed by Dr. Rivers Pollock, and replies were made by Mr. Ralph Straus, Mr. George Belcher, Mr. Warren Low, and Sir Henry Curtis-Bennett. Mr. Warren Low, as president of the Royal Society of Medicine, laid stress on the important part, social as well as educational, played by the smaller medical societies in the progress of medicine.

Fellowship of Medicine and Post-Graduate Medical Association

Arrangements for the coming week will be found in the Medical Diary in another column. There will be a course in practical pathology at the Hospital for Consumption, Brompton, S.W., from Nov. 10th to Dec. 1st, on Thursdays, from 11-45 A.M. to 1 P.M. A demonstration of selected cases of general interest will begin at the Lambeth Hospital, Brook-street, S.E.11, on Friday, Nov. 18th, at 2 P.M. A course consisting of six lecture-demonstrations on Diagnosis and Treatment of Chronic Rheumatism will be held at the British Red Cross Clinic for Rheumatism, Peto-place, N.W., from Nov. 22nd to Dec. 8th, on Tuesdays and Thursdays, at 8.30 P.M. A course in medicine, surgery and gynæcology will be held at the Royal Waterloo Hospital, from Nov. 7th to 26th (afternoons and some mornings). Further particulars may be had from the Secretary of the Fellowship at 1, Wimpole-street, London, W.1.

The Place of Biology in Education

Under the auspices of the British Social Hygiene Council a conference on the place of biology in education will be held at the house of the British Medical Association, Tavistock-square, London, W.C.1, on Nov. 30th and Dec. 3rd. Lord Irwin, President of the Board of Education, will be honorary president of the conference, over which Lord Chelmsford will preside.

A preliminary agenda has been issued from which it appears that on the morning of Nov. 30th Sir Michael Sadler and Sir William Hardy will open a discussion on the National and Imperial Need for a Biological Outlook. In the afternoon two concurrent sessions will be held. At one of these Prof. A. V. Hill, Sir Walter Fletcher, Prof. J. Strong, Mr. F. Herbert Toyne, and Mr. F. Mander will speak on How Local Authorities can promote the teaching of Biology. At the other session Biology in the Training Colleges will be discussed. On Dec. 3rd, the morning session will be devoted to a discussion on Biology in the Central, Senior Elementary, and Junior Elementary Schools, with Prof. Winifred Cullis in the chair, and the afternoon session to a discussion on Biology in the Public, Secondary, and Preparatory Schools. Among the speakers will be Dr. Ralph H. Crowley, senior medical officer, Board of Education, and Mr. G. S. M. Ellis, educational secretary, National Union of Teachers. At this session Mr. W. W. Vaughan, lately headmaster of Rugby, will take the chair and the speakers will include Prof. H. A. S. Wortley, Mr. D. Ward Cutler, and the Rev. Stewart A. McDowall.

Neurological Institute at McGill University

A new neurological institute is to be built at McGill University, Montreal, containing public, private, and semi-private wards, together with the necessary equipment for investigation and research. Its erection is made possible by the grant of over 1,232,000 dollars by the Rockefeller Foundation. The director will be Dr. Wilder G. Penfield, who is at present in charge of the department of neurology and neurosurgery of the University. He will be assisted by Dr. Colin Russel, Dr. F. K. MacKay, and Dr. W. V. Cone.

Freedom Conferred on a Medical Man

After 40 years' service as medical officer of health and school medical officer, the *honorary freedom of the borough* of Morecambe and Heysham was, on Thursday last, bestowed upon Dr. John William Watterson, who is also an alderman of the county of Lancaster and a county and borough magistrate. Dr. Watterson is a native of Burnley, and is the senior partner in the firm of Drs. Watterson, Hogarth, and McFadzean, of Morecambe. Over 2000 people attended the statutory meeting of the Corporation at which the distinction was conferred.

Red Cross Clinic for Rheumatism

Attendances at this clinic in Peto-place, London, N.W., numbered 6091 last month, compared with 5770 in September of last year, and 2684 in September, 1930. The total number of treatments given on the general floor during the month were 4449 to women and 3344 to men, and nearly 1000 treatments were given on the private floor. Provision is now made for remedial exercises in a gymnasium. The equipment was provided by the staff themselves as a contribution to the more effective carrying-out of the work.

Société Médicale du Littoral Méditerranéen

The annual tour organised by this society on the Côte d'Azur will take place this year soon after Christmas. Cannes will be the starting point, and most of the principal towns on this coast will be included in the itinerary. The tour will be under the scientific direction of Prof. Forgue, Prof. Marcel Labbé, and Prof. Laignel-Lavastine; demonstrations and meetings will be held at the various stopping places, and hospitals and other scientific institutions will be visited. Further particulars may be had from the secretary of the society, 24, rue Verdi, Nice. A second tour will be held at Easter.

Portsmouth Mental Hospital

Last week the Lord Mayor of Portsmouth, Alderman F. G. Foster, opened two new villas, to accommodate 124 patients, which have been added to this hospital. One has been named after Dr. H. Devine, formerly medical superintendent, and the other after Alderman W. Gleave, the deputy Lord Mayor. The buildings, which face due south, are planned on three sides of a rectangle, have cost over £27,000. At the opening ceremony last week Dr. T. Beaton, the medical superintendent, stated that during the last four years patients had increased by 200. This "extraordinary increase" was, he said, partly because "patients did not die as they used to," and partly because mental disease is now recognised at a much earlier stage.

New Orthopædic Clinic at Glasgow

The Orthopædic and Rheumatic Clinic of Glasgow is to have new premises in Bath-street. Six years ago the clinic started with five patients; at present 165 are treated daily. The clinic is for people who cannot afford private treatment and who do not wish to receive free treatment in the city hospitals. In its short career it has been run free of debt. In 1931 49,950 patients were given treatment, and as this figure represents an increase of 17,523 on the previous year, more commodious premises were necessary. The clinic is to be opened by the Earl of Home.

Institute of Medical Psychology

A fortnight's course on Functional Nervous Disorders, for members and students of the medical profession only, will open at this institute (formerly the Tavistock-square Clinic) on Nov. 7th. There will be three lectures daily, at 4.45, 5.45, and 8.15 P.M., and they will be given at the new premises in Torrington-place, London, W.C. The lecturers during the first week will be Dr. H. Crichton-Miller (director of the institute), Dr. J. R. Rees (deputy director), Dr. R. G. Gordon, Dr. H. Gardiner-Hill, Dr. Russell Brain, Dr. Alice Hutchison, Dr. E. A. Hamilton-Pearson, and Dr. J. Barrie Murray. Tickets may be had from the hon. lecture secretary, at 51, Tavistock-square, W.C.1, which will be the address of the institute until the end of October. A year's post-graduate course in Psychotherapeutic Theory and Method, for medical practitioners, and also a year's course in the children's department, for psychological students, are now in progress. Particulars of these and subsequent courses may be had on application.

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS

Ottawa Agreements

ON Thursday, October 20th, the House of Commons agreed in Committee to the resolutions dealing with the agreements arrived at between the British Government and the delegates from the Dominions and India at the Imperial Economic Conference at Ottawa. The resolutions were agreed to on Report on the following day.

Ottawa and Cod-liver Oil

On Monday, Oct. 24th, the House of Commons discussed on Report the resolutions agreed to in Committee of Ways and Means in reference to the Bill for the ratification of the trade agreements reached between the British, Dominion, and Indian Governments at Ottawa.

Mr. RHYS DAVIES moved an amendment to omit from the scope of the proposed agreements the duties on oil, castor oil, linseed oil, coconut oil, ground-nut oil, rape oil, and sesamum oil. He said that in 1930 the imports of Norwegian cod-liver oil were approximately 16,000 barrels, and in 1931 approximately 16,500. We imported cod-liver oil from Newfoundland in the ratio of one to 30 compared with Norway, and those who understood the problem said that it did not matter what preference we gave to Newfoundland, we would never be able to supply our market from within the British Empire with this commodity. Why, therefore, were the Government so very drastic in putting 1*s.* 4*d.* per gallon on cod-liver oil? The people affected by cod-liver oil were very largely consumptives. Local authorities spent enormous sums of money in buying cod-liver oil in bulk for use in sanatoria, and they were very apprehensive that their expenses would be considerably increased by the new duties. Cod-liver oil was supplied in very large quantities under the National Health Insurance scheme, and a great deal of the money spent by approved societies for the medicine in respect of 17,000,000 insured persons was expended on cod-liver oil.

Mr. MCKEAG, in supporting the amendment, said that many a child in the north of this country owed its life to being able to obtain cod-liver oil. The current copy of THE LANCET contained two letters by eminent medical authorities. In one case a doctor wrote: "The possibility of a rise in the price of cod-liver oil, as a result of the Ottawa proposals, must arouse some anxiety in the minds of all who are concerned with the welfare of little children, especially those of the poorer class. Cod-liver oil has a value in early life which cannot easily be replaced, unless indeed any adequate supply can be obtained of other fish-liver oils with similar properties." The letter wound up as follows:—

> "For those whose circumstances make a liberal use of eggs, milk, and cream a simple matter, cod-liver oil is unnecessary, but for the poorly fed who cannot obtain these foods in any adequate quantity, cod-liver oil is of very great value, and it would be a bad day for the children when the price of cod-liver oil rose sufficiently to prevent its use for every child who is needing it."

A lady doctor, of the Lister Institute of Preventive Medicine, also writing in THE LANCET, said: "It is evident that any steps which may raise the price and lower the consumption of cod-liver oil, especially in winter, would have a deleterious effect upon the health of the population, involving particularly the well-being of the children of the poorer classes." The proposed tax, Mr. McKeag continued, could have no other result but to increase the price of cod-liver oil to the poorer people. Of the annual consumption of 500,000 gallons of cod-liver oil, only 25,000 gallons were obtained from Newfoundland, and therefore 475,000 gallons were to be taxed in order to give Newfoundland an increased price.

Mr. H. G. WILLIAMS said that this country was a large cod-liver oil producing country, and last year 5,000,000 cwts. of cod-fish were landed on our shores. These fish were cleaned when caught and the livers taken apart. If the livers were boiled immediately they would give cod-liver oil of medicinal quality, and in some cases boilers for that purpose were provided on the trawlers. The practice in this country in the past had been, to a large extent, in the case of the trawlers going long distances to wait until they reached shore before boiling the livers, which were then rather stale. That produced oil of an industrial quality, which had high medical qualities but was not pleasant to the palate and was therefore mainly used for cattle, and was not given to children. The amount of the duty was 4*d.* a quart, and to the consumer the duty would be not more than 4 or 5 per cent. All that was wrong with our own production was that we were producing relatively too much industrial and not enough medicinal cod-liver oil. We could increase our total production to a substantial extent, and Newfoundland and the United Kingdom could supply all the oil that was needed in admirable qualities at reasonable prices.

Mr. MALLALIEU said that in its issue of Oct. 15th THE LANCET said:—

> "A leading newspaper last Sunday, in dismissing opposition to the Ottawa Agreements, remarked that even the dissenting Liberals 'cannot be exactly stirred to the depths by the reflection that their cod-liver oil will cost them more.'"

and THE LANCET went on to say:—

> "The medical profession is hardly likely to share this light-hearted view of the proposed duties. Year by year it is made clearer that the diet of the poorer classes, if not the richer, is not the 'balanced diet' advised by the text-books. Report after report on rickets, dental caries, maternal mortality, or infectious disease, emphasises the importance of plenty of fresh foods, or, if these are too expensive, of cod-liver oil."

Continuing, Mr. Mallalieu said that the reason why we had been buying cod-liver oil from Norway in the past was because cod-liver oil was produced in Norway under conditions which were most suitable. It was an acknowledged fact that for medicinal purposes cod-liver oil must be produced from fresh livers. It was of no use for medicinal purposes when the livers had become even slightly decomposed. In Newfoundland the fishing was in two of the hottest months of the year, whereas in Norway the fishing was conducted in March and February. In Norway there were admirable factories, some of them owned by British people, whose products the Government proposed to tax on entry into this country. The whole production was concentrated in a very small area, whereas in Newfoundland the production was carried on by small scattered producers whose transport costs were naturally very much more than those of the Norwegians.

Dr. BURGIN (Under-Secretary for the Dominions) said that there were two points with regard to cod-liver oil which the Government had to meet. The first was with regard to the retail price of the ordinary quantity of cod-liver oil required for consumption by children and patients in hospitals. The normal method of selling cod-liver oil was in an 8-oz. bottle or some other regular standard bottle. There was no evidence in the possession of the Government that would lead one to think that the price was going to be increased. They were also advised that the increase in price to any individual farmer for oil for cattle feeding was likely to be quite insignificant. Those two comments broadly disposed of the whole of the case that was made either in THE LANCET or elsewhere with regard to cod-liver oil. The real truth was that there were only certain things that Newfoundland could produce. The cod fisheries and cod-liver oil production were one of Newfoundland's greatest assets. It was tragic that, owing to lack of demand, something like a third only of the total possibilities of cod-liver oil had been produced in Newfoundland in recent years. It was the hope of the Government that by this method something might be done to encourage that great industry without appreciable extra cost to the consumer.

The amendment was rejected by 264 votes to 64—majority 200.

The Need Test

On Friday, Oct. 21st, Mr. MACDONALD (*Prime Minister*), replying to Mr. CROOKE, stated that the Government proposed to introduce and pass through all its stages before the end of the present session legislation to deal with certain aspects of the administration of the Need Test. (Cheers.)

HOUSE OF COMMONS

THURSDAY, OCT. 20TH

Dangerous Driving

Mr. ROBINSON asked the Home Secretary whether he was aware that the regulations as to dangerous driving were not being adequately enforced in many areas; and whether he would give instructions to police forces throughout the country to take special notice of the speeds at which heavy commercial vehicles were driven through small towns and villages.—Mr. STANLEY replied: The attention of chief officers of police was specially directed to this matter by my right hon. friend's predecessor a few months ago, and there is no reason to doubt that all practicable steps are taken by the police to check excessive speeding on the part of drivers of heavy vehicles. As at present advised, my right hon. friend does not think that any further instructions on the subject are called for.

Water Pollution Research

Sir COOPER RAWSON asked the Lord President of the Council whether he could furnish any information on the result of the investigations of the microbiology laboratory at the Rothampsted station at Harpenden with regard to the suffocation of fish owing to the discharge into rivers of the residue of fats in water in which churns and other equipment from milk factories and large dairies were cleansed.—Mr. BALDWIN replied: The investigations referred to, which are being carried out at Rothamsted under the auspices of the Department of Scientific and Industrial Research as part of the programme of the Water Pollution Research Board, are not yet complete, though important results have been obtained. There is good reason to expect that milk effluents can be rendered innocuous by filtration methods, and the main problem remaining is to discover an economical method of getting rid of fatty film which accumulates on top of the filter bed.

The Umckaloabo Treatment

Sir COOPER RAWSON asked the Minister of Health whether he had further considered the treatment for tuberculosis known as umckaloabo, and the cases in which it was claimed cures had been effected: and if he would institute an official inquiry into the merits of the system.—Sir E. HILTON YOUNG replied: The evidence available in regard to the efficacy of this preparation has been carefully considered on several occasions. I am advised that the claims made on its behalf in regard to tuberculosis do not appear to differ in character or degree from those made for many other so-called "remedies" which have been advertised from time to time and afterwards found to be valueless. The answer to the second part of the question is in the negative.

Assistance to Deaf and Dumb Persons

Mr. ROBINSON asked the Minister of Health whether he was aware of the discrepancy which existed between the provisions made for the treatment of blind persons and those who were deaf and dumb: and whether he would consider taking steps which would ensure that deaf and dumb persons were placed on a level with the blind in respect of assistance given from public sources.—Sir E. HILTON YOUNG replied: The report recently made to my department and the Board of Education on an investigation into the conditions of the deaf and dumb in this country will shortly be published. In the meantime it is not possible to contemplate the introduction of legislation on this subject.

Psittacosis

Mr. TURTON asked the Minister of Health how many cases of psittacosis had been reported in this country before the present restrictions upon the importation of parrots were imposed four years ago, and how many cases had been reported since the restrictions were imposed; and whether, in view of the inconvenience the restrictions caused, he could relax or abolish them.—Sir E. HILTON YOUNG replied: Some 125 cases of psittacosis were reported in this country before the present restrictions came into force, and four cases have been reported since. In view of the fact that further cases of this disease have recently occurred in the United States of America and on the Continent of Europe, and that the Office International d'Hygiène Publique have recommended the maintenance of existing prohibitions, I cannot see my way at present to relax or revoke the Regulations in force in this country.

Children in Poor-law Institutions

Mr. LOVAT-FRASER asked the Minister of Health how many children over the age of 3 were living in poor-law institutions in the county of Cornwall and within the area of the Isle of Ely county council respectively.—Sir E. HILTON YOUNG replied: I am informed in a recent report of my general inspector that there are 60 children over 3 in poor-law institutions (as distinguished from children's homes) in the county of Cornwall, and that there are 32 such children in poor-law institutions in the Isle of Ely.

Infantile Mortality

Mr. RHYS DAVIES asked the Minister of Health if he could give the infantile mortality-rates for London, New York, Chicago, Paris, Berlin, Vienna, and Moscow for the last year for which statistics were available.—Sir E. HILTON YOUNG replied: The latest year for which comparative statistics are available for all these cities is 1929. The infantile mortality-rates (number of deaths under one year per 1000 live births) in that year were as follow: London, 71; New York, 59; Chicago, 60; Paris, 101; Berlin, 86; Vienna, 79; and Moscow, 129. These figures are given in the League of Nations publication, "Statistics of Notifiable Diseases, 1929."

MONDAY, OCT. 24TH

Milk Reorganisation Report

Captain PETER MACDONALD asked the Minister of Agriculture by what date the report of the Milk Reorganisation Committee would be available.—Major ELLIOT replied: The Milk Reorganisation Commission is, I understand, now considering its recommendations, and its report is expected to be available before the end of this year.

Employment of Juveniles

Viscountess ASTOR asked the Home Secretary whether it was the intention of the Government to bring before Parliament at an early date a resolution authorising local authorities to make by-laws relating to the hours and conditions of employment of juveniles.—Sir JOHN GILMOUR replied: I presume that the noble lady refers to Section 51 of the Children and Young Persons Act, 1932, which confers powers upon local authorities to regulate by by-laws the employment in certain occupations of persons between 14 and 18 years of age. Subsection (4) of that section provides that an order of the Secretary of State appointing a date for these powers to come into operation shall not become effective until it has been approved by resolutions passed in the same session of Parliament by both Houses of Parliament. I would refer the noble lady to the statements made by the Government spokesman when this provision was under discussion in this House. The Government spokesman stated that it was not the intention of the Government that this question should be dealt with merely by bringing into operation Section 51 of the Children and Young Persons Act, 1932. He made it clear that it was the intention of the Government, when they came to deal with this question, to bring it before Parliament in the form of a Bill.

NEW WING AT PORT TALBOT HOSPITAL.—Last week the Bishop of Llandaff dedicated a new children's wing as a memorial to the late Sir Sidney Byass at the Port Talbot Memorial Hospital.

HULL ROYAL INFIRMARY.—Mr. R. J. Lowson has compiled an account of "The Hull Royal Infirmary, 1782–1932," to which have been added biographical notes of the hon. medical staff by Dr. Robert Grieve. This admirable little addition to hospital historical literature contains many interesting details, especially in regard to the early days of the institution. One of its benefactors in the beginning was Sir Henry Etherington, who disapproved of the maintenance of an honorary staff, suggesting that only one physician and one surgeon should be employed and that they should be paid. "I suppose," he wrote, "the physician would not expect more than two guineas per week, that being the usual fee for twice attendance every day." There were originally 60 beds: there are now 397.

OBITUARY

ATWOOD THORNE, M.B.Lond.

Dr. Atwood Thorne, who died at Caerleon on Oct. 6th, was born in 1867 in Shanghai, the son of Mr. J. Thorne, and received his general education at Brighton College, proceeding to St. Mary's Hospital for his medical training. A successful student, he held the appointments of house surgeon and obstetric officer at the hospital, and was assistant in the laryngological department for two years. This determined his later special work: he was elected surgeon to the London Throat Hospital, was a vice-president of the British Laryngological, Rhinological, and Otological Association, and for a period was secretary of the Laryngological Section of the R.S.M. He was also the author of a small book dealing with the education of the deaf in the metropolitan area.

Atwood Thorne was known prominently as a medico-military volunteer. He had been a volunteer as a lad, and when he served as a surgeon-captain C.I.V. in the South African War, where he was mentioned in despatches, he was already in receipt of the V.D. In the late war he was appointed honorary Colonel R.A.M.C., held two responsible administrative posts, and received the Queen's medal and three clasps.

Apart from his medical and military interests, Atwood Thorne was a considerable archæologist, and, when on retirement he decided to live at Caerleon, he took an active interest in the excavation of Roman remains in the neighbourhood, some of them on his own property. He also made a valuable collection of pink lustre pottery, which he described in a beautifully illustrated book. He was for two years master of the Cutlers Company.

In the many different and important contacts which he made with life Atwood Thorne earned deservedly the high regard of his fellows.

AFTER more than a year of ill-health Dr. GEORGE BLAKE MASSON died on Oct. 11th, at Litlington, near Alfriston, in Sussex. A son of Colonel Masson, and grandson of General George Blake, he was born at Darjeeling 72 years ago. He got his medical education at Cork and Dublin and in Edinburgh where he qualified in 1883. Most of his professional life was spent in Norfolk, first at Saxlingham, near Norwich, and later at Fincham, Downham Market. Here Dr. Masson practised until the war, acting as medical officer and public vaccinator of his district. When war broke out he already held a major's commission in the Territorials, being attached to the 2nd East Anglian Field Ambulance, and on service in France he was promoted Lieut.-Colonel. In 1920 he went to practise at Alfriston and he remained in active work there until his illness last year. A good shot and a rider to hounds, he was popular in the district and made many friends. He is survived by his widow.

Dr. HENRY JAMES BAILEY, who died on Oct. 10th at the age of 67, was one of the senior medical practitioners of Brighton. He graduated at Edinburgh in 1887 and after holding a house appointment at the Royal Albert Hospital, Devonport, came to London to work as assistant medical officer in the London Medical Mission Dispensary. Thence he went out to Palestine, where his father was engaged in mission work, and became medical superintendent of the Church Missionary Society's hospital and dispensary at Nablus. He spent several years there, and when he returned to England lived at Southport before settling down finally at Brighton. Here he acquired a large practice, and a few years ago was joined in partnership by Dr. Ivor Kinsley. Dr. Bailey leaves a widow and one son, Mr. Hamilton Bailey, who is surgeon to the Royal Northern Hospital.

ON Oct. 8th Dr. SAMUEL WELLESLEY COOMBS died at Poole in Dorset, aged 76. For many years he was one of the leading practitioners of Worcester, where he was associated with the Dispensary for over 40 years. Son of the late Harold Coombs, of Worcester, he was educated at the local grammar school, and qualified from Glasgow in 1878, gaining the Richardsonian prize. After holding house appointments at the Glasgow Royal Infirmary he returned to Worcester and became medical officer to the Dispensary. In 1881 he became F.R.C.S. Edin., and later he was appointed anæsthetist to the Infirmary. When in 1919 he relinquished his post as district medical officer he told the Board that he had kept records of his professional mileage during 40 years, and found that during this time he had cycled 110,000 miles, driven horses 90,000 miles, and motored 40,000, making 240,000 miles in all—or once round the world in every four years. On his retirement in 1919, when he went to live at Poole, Dr. Coombs was succeeded by his partner, Dr. F. L. Spalding. He married in 1883, and leaves a son and two daughters.

Dr. MATTHEW LOVELL MACKINTOSH, who died in London on Sept. 26th, followed his father as a practitioner in the Crowborough district. After taking the Scottish conjoint diploma in 1890 he served as a ship's surgeon with the Clan line, and returned to practise for a time at Barrow-in-Furness, before finding his permanent home in Sussex. He was on the staff of the Crowborough Cottage Hospital, and was a keen supporter and follower of many kinds of sport.

Births, Marriages, and Deaths

BIRTHS

BRODIE.—On Oct. 24th, at Melbourne, Australia, the wife of Dr. C. E. Brodie, of a son.

FRASER.—On Oct. 18th, at Lima House, Reading, the wife of Dr. H. D. Forbes Fraser, of a daughter.

JAMES.—On Oct. 22nd, at The Lawn, Hillingdon, Middlesex, the wife of Dr. G. W. B. James, of a son.

McCORMICK.—On Oct. 20th, at Welbeck-street, W., the wife of Dr. Edward William McCormick, of a son.

MARRIAGES

WOODD-WALKER—TROILI.—On [illegible] Sweden, Geoffrey Basil Woodd-Walk[illegible] en [illegible] Anne-street, W.1, and 6, Da[illegible] ll, of Uddeholm, Sweden.

DEATHS

BULCOCK.—On Oct. 16th, suddenly, at Foxley-lane, Purley, Dr. Joseph Henderson Bulcock.

McLAREN.—On Oct. 21st, Dr. Thomas McLaren, of 27, Bruce-grove, Tottenham, London, N.17.

MURPHY.—On Oct. 14th, suddenly, at Dangan Cottage, Thomastown, of acute gastro-enteritis, Patrick Joseph Murphy, F.R.C.S.

POPE.—On Oct. 19th, 1932, at Southend, Percy Pope, M.R.C.S., L.R.C.P., M.D.

SMITH.—On Oct. 17th, John Salmon Smith, M.R.C.S., L.R.C.P. Lond., D.P.H, Camb., of West Road, Old Colwyn, late West African Medical Service.

WEISS.—On Oct. 15th, Major Willoughby Gaspard Weiss, V.D., T.D., Dental Surgeon, aged 75.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical Diary

SOCIETIES

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

Tuesday, Nov. 1st.—5.30 P.M., Orthopædics (Cases at 4.30 P.M.) Cases: Mr. E. P. Brockman: 1. Osteitis of the Os Calcis. 2. Ewing's Tumour. Mr. R. Brooke: 3. Localised Decalcification of the Knee-joint. 4. X Ray Pictures of a Similar Case. Mr. Alan Todd: 5. Syringomyelia with Scoliosis. 6 Scoliosis with Paraplegia (Recovered). Further report of a case shown in 1930. Other cases will be shown.—8.30 P.M., Pathology. Laboratory Meeting at the Pathological Institute, London Hospital, E 1. Demonstrations: Dr. S P. Bedson and Dr. J. O. Bland: Developmental Forms of Psittacosis Virus. Dr. J. O Bland and Dr. D. S. Russell: Tissue Cultures of Various Types of Glioma. Dr. D. T. Harris: A Continuous Kataphoresis Apparatus suitable for Bacteriology. Dr. T. Lumsden: Some Effects of Radiation on Tissues. Dr. E. P. Stibbe: Some Congenital Abnormalities. Dr. H. M. Turnbull: Bony Changes in Cœliac Disease and Renal Rickets Dr. F. C. O. Valentine: A Modification of the Direct Method of Typing Pneumococci Dr. J. Vaughan: Erythroblastic Anæmia Associated with Cœliac Disease. Dr. W. W. Woods and Dr. A. B. Bratton: Pathological Specimens.

Wednesday.—5 P.M., History of Medicine. Papers: Dr. Vincent Dickinson: The Outbreak of Plague at Milan in 1630. Dr Aubrey Lewis: Melancholia. 8.30 P.M., Medicine and Surgery. Special Discussion on the Treatment of Acute Appendicitis. Openers: Dr. J. A. Ryle (Medicine) and Mr. H. H. Rayner (Surgery).

Thursday.—Semon Lecture. 8.30 P.M., Tropical Diseases and Parasitology. Symposium on the Pathology of Bucco-pharyngeal and Skin Ulcers. Mr. T. Pomfret Kilner: The Surgical Aspects of Certain Skin Ulcers. Dr F. C. Smith: The Pathology of Tropical Ulcer with Especial Reference to the Distribution in the Lesion of *B. fusiformis* and *Spirochæte schaudinni*. Sir Aldo Castellani: Blastomycetic Ulcers. Dr. W. Broughton-Alcock: Spirochætal Ulcers of the Mouth and Skin. Dr. J. G. Thomson: The Pathology of Dermal Leishmaniasis. Members of these Sections of ([illegible] Dermatology, and Pathology a [illegible] attend and to take part in the subsequent discussion.

Friday.—10.30 A.M., Otology (Cases at 9.30 A.M.) Discussion: The Treatment of Lateral Sinus Thrombosis. Openers: Mr A. E. Peters and Mr. F. Wilson. Cases and specimens will be shown. 5 P.M., Laryngology. (Cases at 4 P.M.) Presentation of portrait to Sir StClair Thomson. Presidential address by Mr E. Musgrave Woodman. Cases and specimens will be shown by Mr E. Broughton Barnes, Mr Herbert Tilley, Mr E. D. D. Davis, and others. 8.30 P.M., Anæsthetics. Dr C. F. Hadfield: Modern Aids to Anæsthesia (Presidential address.) Members of the Section of Comparative Medicine are specially invited to attend.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

Friday, Nov. 4th.—8.30 P.M. (at the West London Hospital), Mr. O. L. Addison: Chronic Pyuria in Children.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, S.W.

Tuesday, Nov. 1st.—5 P.M., Dr. Dugald Baird: The Upper Urinary Tract in Pregnancy. (Bradshaw lecture.)

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's inn Fields.

Monday, Oct. 31st.—5 P.M., Mr. R. Davies-Colley: Intestinal Cysts and Diverticula.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

Monday, Oct. 31st, to Saturday, Nov. 5th.—Medical Society of London, 11, Chandos-street, Cavendish-square, W.1. Tues., 4 P.M., Series of Lectures on Renal Disease by Dr. A. Arnold Osman: Nephritis and Nephrosis. (Free to Members.)—Hospital for Sick Children, Great Ormond-street, W.C. Diseases of Children. Mornings only.—West End Hospital for Nervous Diseases, 73, Welbeck-street, W. A Course in Neurology, daily at 5 P.M., Oct. 31st to Nov. 26th.—Royal Westminster Ophthalmic Hospital, Broad-street, W.C. A Course in Ophthalmology. Afternoons: Oct. 31st to Nov. 19th.—10, Bedford-square, W.C. Dr. A. Knyvett Gordon will give a demonstration on Clinical Pathology (Epidiascope and Laboratory) on Wed. at 8.30 P.M. (Specially suitable for M.R.C.P. Candidates.)

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE, Hammersmith-road, W.

Monday, Oct. 31st.—10 A.M., Skin Department, Surgical Wards. 2 P.M., Eye and Gynæcological Out-patients.

Tuesday, Nov. 1st.—10 A.M., Medical and Surgical Demonstrations. 2 P.M., Throat, Nose, and Ear Out-patients. 4.15 P.M., Lecture, Dr Owen: The New-born Child.

Wednesday.—10 A.M., Medical Wards, Children's Out-patients. 2 P.M., Eye Out-patients. 4.45 P.M., Venereal Diseases Demonstration.

Thursday.—10 A.M., Neurological Out-patients, Fracture Demonstration. 2 P.M., Eye and Genito-Urinary Out-patients. 4.15 P.M., Lecture, Dr. Shaw: Jaundice.

Friday.—10 A.M., Medical Wards, Skin Department. 2 P.M., Throat, Nose, and Ear Out-patients. 4.15 P.M., Lecture, Dr. R. Ironside: The Nervous System.

Saturday.—10 A.M., Medical Wards, Children's Out-patients, Surgical Wards.

Daily, 2 P.M., Operations. Medical and Surgical Out-patient Departments.

The lectures at 4.15 P.M. are open to all medical practitioners without fee.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 49, Leicester-square, W.C.

Monday, Oct. 31st.—5 P.M., Dr. G. B. Dowling: Mycotic Diseases.

Tuesday, Nov. 1st.—5 P.M., Dr. H. MacCormac: Diseases Due to Animal Parasites.

Thursday.—5 P.M., Dr. W. J. O'Donovan: Occupational Dermatitis.

NATIONAL HOSPITAL, Queen-square, W.C.

Monday, Oct. 31st.—2 P.M., Dr. Riddoch: Out-patient Clinic. 3.30 P.M., Dr. Kinnier Wilson: The Motor System.

Tuesday, Nov. 1st.—2 P.M., Dr. Walshe: Out-patient Clinic. 3.30 P.M., Dr. Martin: Intercranial Pressure.

Wednesday.—2 P.M., Dr. Martin: Out-patient Clinic. 3.30 P.M., Dr. Collier: Clinical Demonstration.

Thursday.—2 P.M., Dr. Kinnier Wilson: Out-patient Clinic. 3.30 P.M., Dr. Kinnier Wilson: The Motor System.

Friday.—2 P.M., Dr. Adie: Out-patient Clinic. 3.30 P.M., Dr. Bernard Hart: Psychoneuroses.

HAMPSTEAD GENERAL AND NORTH-WEST LONDON HOSPITAL POST-GRADUATE SCHOOL.

Wednesday, Nov. 2nd.—4 P.M., Dr. H. V. Morlock: Recent Advances in the Diagnosis of Pulmonary Disease.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn-road, W.C.

Friday, Nov. 4th.—4 P.M., Mr. C. Gill-Carey: Foreign Bodies in the Food and Air-passages.

ST. PETER'S HOSPITAL FOR STONE, POST-GRADUATE COURSE, Henrietta-street, Covent Garden, W.C.

Wednesday, Nov. 2nd.—3 P.M., Mr. J. Swift Joly: Vesical Calculus.

ST. PAUL'S HOSPITAL, Endell-street, W.C.

Wednesday, Nov. 2nd.—4.30 P.M., Mr. R. H. Jocelyn Swan: Hæmaturia.

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL, Denmark-hill, S.E.

Thursday, Nov. 3rd.—9 P.M., Mr. St. J. D. Buxton: *Injuries of the Hand.*

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION, St. James' Hospital, Ouseley-road, Balham, S.W.

Wednesday, Nov. 2nd.—4 P.M., Dr. Stanley Wyard: Medical Progress 1932.

ROYAL INSTITUTE OF PUBLIC HEALTH, Queen-square, W.C.

Wednesday, Nov. 2nd.—4 P.M., Mr. M. Donaldson: The Cancer Problem in Relation to the General Practitioner.

Thursday.—4 P.M., Dr. R. M. Stewart: Causation of Mental Deficiency.

CHADWICK PUBLIC LECTURES.

Tuesday, Nov. 1st.—5.15 P.M., (at the Royal Society of Tropical Medicine and Hygiene, 26, Portland place, W.), Prof. Keilstra (Leyden): Hygiene in the Far East.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE LECTURES.

Tuesday, Nov. 1st.—4.15 P.M., Dr. A. Ramsbottom: Treatment of Indigestion.

Friday.—4.15 P.M., Mr. J. P. Buckley: Demonstration of Surgical Cases.

ANCOATS HOSPITAL, Manchester.

Thursday, Nov. 3rd.—4.15 P.M., Mr. P. G. McEvedy: Infection Treatment.

GLASGOW POST-GRADUATE MEDICAL ASSOCIATION.

Wednesday, Nov. 2nd.—4.15 P.M. (at the Royal Hospital for Sick Children), Prof. G. B. Fleming: Pneumonia in Infancy and Childhood.

Appointments

Beresford, A. L., M.B., Ch.B. Liverp., has been appointed Certifying Surgeon, under the Factory and Workshop Acts, for the Glyn Ceiriog District, Denbigh.

Condy, E. M., M.B., B.Ch. Belf., D.P.H., Medical Officer, Caledon Dispensary District, Tyrone.

Gemmell, A. A., M.D. Camb., F.R.C.S. Edin., Gynæcological and Obstetrical Surgeon, David Lewis Northern Hospital, Liverpool.

Reid, Margaret S. M., M.D., Ch.B., D.P.H., Resident Medical Officer, Isolation Block, Queen Charlotte's Hospital, Hammersmith.

London County Council: Gunn, A. L., F.R.C.S. Edin., M.D. Wales, Senior Assistant Medical Officer, Grade II., St. Leonard's; Harley, H. C., B.M., B.Ch. Oxf., Assistant Medical Officer, Grade I., Lewisham; Leiper, E. J. R., M.B., Ch.B. Aberd., Assistant Medical Officer, Grade II., St. Stephen's; Madel, G. A. M., L.R.C.P., M.R.C.S., House Physician, St. James's; and Weinstein, Celia, L.R.C.P., M.R.C.S., House Physician, Lewisham.

NOTES, COMMENTS, AND ABSTRACTS

A GRUESOME FAMILY

THERE recently appeared at the Clerkenwell police-court, on a charge of larceny, a lad of 18, accompanied by a younger lad whom he was said to have led into trouble. The magistrate, Mr. Claud Mullins, instituted inquiry into the family history of the elder boy, whose low mentality was apparent to him. He asked the boy's father how many other children he had, a question which the father was unable to answer promptly; but he made calculations on his fingers, eventually arriving, with the help of the magistrate, at a total which proved to be wrong. The father was out of work, and could not read the words of the oath. On the boy coming before the court later, on remand, the magistrate read out some of the information which he had received, to the following effect. The father, aged 62, was living with the mother and 11 of his children and grandchildren in two rooms. Certain of his children were adults, and six adults with four children were sleeping in one room. The father's family had been made up as follows: (1) Daughter, 32, attended mental deficiency school as a child, married, with children, one of whom is at M.D. school. (2) Daughter, 31, married; one child at M.D. school. (3) Daughter, 30, married. (4) Son, 28, attended M.D. school, married, and wife deserted him; three children, two stammerers, and one with very bow legs. (5) Daughter, 26, attended M.D. school, married. (6) Daughter, 24, attended M.D. school. (7) and (8) Twin boys, died in infancy. (9) Son, 22, attended M.D. school, on dole. (10) Boy, died of scarlet fever in infancy. (11) Son, 18—the prisoner. He attended M.D. school and left "able to read two-syllable words with difficulty." Said to be "lazy, self-willed, and subject to occasional violent outbursts of temper." Was constantly truanting or late. Prison doctor now certified him as feeble-minded. (12) Boy, died at five days of "hæmorrhage." (13) Boy, 16, out of work; has exhausted his dole. (14) Daughter, 13, a diphtheria-carrier, and now in the fever hospital. The mother stated that so far she had 19 grandchildren.

MATERNITY IN THE AUSTRALIAN BUSH

IT may be recalled that, at the end of 1927, after a two years' inquiry into the causes of maternal mortality and morbidity in the State of Victoria, Dr. R. Marshall Allan published the surprising fact that 2273 confinements had been conducted between the years 1922 and 1927 by members of the Bush Nursing Association without a single maternal death. In an outline of the Association, recently written by the hon. secretary, Sir James Barrett, vital statistics for the years 1931–32 show that, though a mortality-rate of none per thousand has not been maintained, as indeed could hardly be expected, the rates, not only of maternal deaths, but also of neonatal deaths and stillbirths are far lower than those for the State as a whole, the figures per 1000 live births being:—

	B.N.A.	*State.*
Maternal death-rate.. ..	1·9	4·9
Neonatal death-rate.. ..	14·9	30·1
Stillbirth rate..	17·0	29·7

Actually there was one maternal death out of 948 deliveries. Bush nurses have always worked in close association with the medical profession, and the establishment of additional Bush nursing hospitals, and their popularity, have led to an increasing number of confinements taking place in these institutions. The percentage of patients receiving antenatal care is exceptionally high; in the year ended June, 1931, bush nurses attended 1044 maternity patients and gave antenatal advice to 893 of them. These nurses hold a threefold certificate—for general nursing, midwifery, and infant welfare. They are also skilful in gaining the confidence of their patients and persuading them to visit a doctor for antenatal examination. This team-work results in timely recognition of abnormality or a risk of it, followed by prompt treatment.

A STAFF OFFICER'S TRAVELS.

Dr. J. Johnstone Redmond sends us some interesting particulars taken from the diary of his grandfather, Gabriel Redmond, M.D., a former inspector-general of military hospitals. In 1812 this officer was ordered to Canada to inspect and report on the military hospitals, England then being at war with the United States. He left Spithead on August 27th and arrived at Quebec on Oct. 10th after a stormy voyage during which they were attacked by an armed privateer. In those days officers supplied their own rations to a large extent, and Redmond for his own party—consisting of wife, child, maid, and manservant—took on board the following provisions: one dozen port wine, two dozen Madeira, five dozen porter, one goat, three sheep, and three dozen and nine fowls, together with salt beef, salt pork, biscuit, oatmeal, pease, flour, sugar, coco, and two quarts of rum. During his tour of Canada he covered in open wagons, open boats, on sloops of war, in sledges, carriages, and stage coaches, but mostly on horseback, a total of 1354 miles.

Vacancies

For further information refer to the advertisment columns

[illegible] *ty Borough.*—Asst. M.O. £500.
[illegible]—Second H.S. At rate of £140.
[illegible] *Monk's Orchard, Beckenham, Kent.*—[illegible]nologist.
Birmingham and Midland Ear and Throat Hospital.—Asst. Surg. O. £200.
Birmingham, Dudley-road Hospital.—Jun. Asst. M.O.'s. All at rate of £200.
Blackpool C[illegible]—Asst. School M.O. £550.

The Chief Inspector of Factories announces vacancies for Certifying Factory Surgeons at Exmouth (Devon); Southminster (Essex); and at Wantage (Berks.)

ADDRESSES AND ORIGINAL ARTICLES

THE UPPER URINARY TRACT IN PREGNANCY*

BY DUGALD BAIRD, B.Sc., M.B. GLASG., M.C.O.G.

ASSISTANT TO THE MUIRHEAD PROFESSOR OF OBSTETRICS AND GYNÆCOLOGY IN THE UNIVERSITY OF GLASGOW; ASSISTANT PHYSICIAN TO THE GLASGOW ROYAL MATERNITY AND WOMEN'S HOSPITAL; AND ASSISTANT GYNÆCOLOGIST TO THE GLASGOW ROYAL INFIRMARY

IT has been long recognised that dilatation and stasis of the upper urinary tract occur frequently in pregnancy, but although much information about the nature of the change has been gained recently through the development of urological methods, its significance and cause are not yet fully understood. One of the earliest workers on the subject was Opitz,[1] who came to the conclusion from the examination of post-mortem material that the condition was due to compression of the ureter, especially the right, between the uterus and the structures at the pelvic brim. The work of Carson [2] and others supports this view. The observation that the dilatation in some cases extends throughout the whole length of the ureter led Stoeckel [3] and others to believe that it was due to a general atony of the urinary tract. Hofbauer [4] found a definite hyperplasia of the wall and sheath of the ureter at its lower end and believes that this constitutes an obstruction to outflow at the bladder, causing the dilatation of the ureter throughout its whole length. More recently by the application of urological methods much interesting work has been done, especially in Germany, on the relationship of this anatomical change to disorders of function. Gremme [5] comparing the views of the various workers comes to the conclusion that there is atony of the upper urinary tract in pregnancy which makes it possible for the ureter, especially the right, to be compressed between the uterus and the psoas muscle, that dilatation of the urinary tract does not necessarily mean the presence of stasis, and that there may be delay in emptying the upper urinary tract without the kidney function being affected.

The problems we are confronted with are, the cause of the primary atony which appears to be the chief factor in the production of the dilatation, what effect these changes which occur in pregnancy have on ureter and kidney function, and what bearing they have on the occurrence of infection, with particular reference to pyelitis of pregnancy. Towards their solution I have attempted an investigation from every aspect, and in this lecture I wish to correlate the results obtained by post-mortem, clinical, and urological examinations.

Post-mortem Examination

NAKED-EYE APPEARANCES

The ureters in 102 women, who have died during pregnancy or within a few days of delivery, have been examined. Eighteen were less than seven months pregnant and are not included in the first analysis.

From Table I. we see that 85 per cent. of these cases show some dilatation of the right urinary tract and 72 per cent. some dilatation of the left. Dilatation, as is generally recognised, is more marked on the right side but, contrary to what has often been stated, is more marked in primigravidæ than in multiparæ. The right ureter shows a one-plus dilatation or more in 69 per cent. of the primigravidæ and in only 25 per cent. of the multiparæ. The same thing is seen on the left side.

In 48 cases the distortion was of the type which I consider to be characteristic of pregnancy. It is asymmetrical. On the right side the ureter is dilated from the pelvic brim upwards and is markedly elongated and kinked. The kinks vary in number and distribution, but the most common site is the junction of the upper and middle thirds. They may be very acute and cause marked narrowing of the lumen. They are sufficiently permanent to remain after removal of the tract from the body, but histologically the trabeculæ keeping the loops in position are seen to be very slender. The dilatation also affects the kidney pelvis and calyces. Below the pelvic brim there is often no dilatation of the ureter or, if present it is seldom marked, so that at this level an abrupt narrowing of the lumen usually occurs. On the left side some dilatation is usually present but it is more uniform throughout the length of the ureter, extending down to the bladder so that there is no abrupt demarcation at the pelvic brim, such as is present on the right side, and the left ureter may actually be more dilated than the right just below the pelvic brim. Occasionally the dilatation of the left urinary tract also is marked, in which case the deformity on the left side resembles that typical of the right side. As a general rule where the dilatation was marked on the right side, it was pronounced also on the left to a less degree, but occasionally, where the right urinary tract was enormously dilated, the left showed only a very slight dilatation. This point is illustrated in Fig. 1.

TABLE I

Dilatation.	Primigravidæ (32).			Multiparæ (52).		
	Right.	Left.		Right.	Left.	
None.	2	5		10	18	
± − −	2	7		4	13	
± −	6	7		24	12	
+	12	10		7	6	
+ +	8	1		5	2	
+ + +	1	2		2	1	
+ + + +	1	0		0	0	
+ to + + + +	69 %	40·6 %		25 7 %	17·3 %	

Dilatation of + indicates a urinary tract with a total capacity kidney and ureter of 20–30 c.cm.; + + 30–50 c.cm.; + + + 50–70 c.cm., and + + + + over 70 c.cm. One + therefore represents a fairly marked dilatation.

In six cases the dilatation was more marked on the left than on the right.

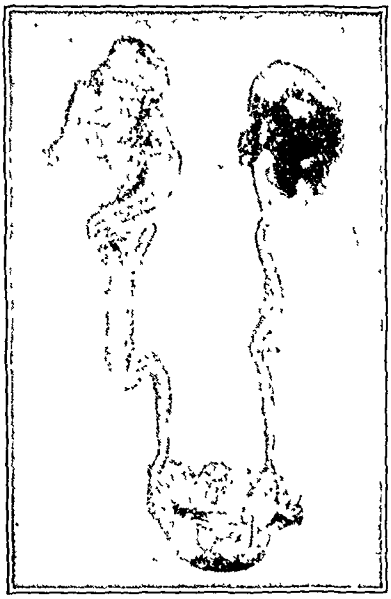
In the 18 patients who died at or before the sixth month 27 per cent. showed a one-plus dilatation of the right ureter and 11 per cent. a one-plus dilatation of the left. The primigravidæ had greater degrees of dilatation than the multiparæ. Minor degrees of dilatation are not easily assessed by this method.

The cause of death did not appear to bear any relationship to the amount of dilatation present except in cases of toxæmia, where it was consistently very slight. There were 14 multiparæ who died of toxæmia, including eclampsia, albuminuria, and ante-partum hæmorrhage. None of these showed a one-plus dilatation, most showing very little at all. For the rest of the multiparæ in this series, the incidence of one-plus dilatation was 40 per cent. This corresponds with the urological finding that there is an absence of delay in excretion in the toxæmic cases. Anselmino, Hoffman, and Kennedy[6] have shown that, in the toxic albuminuria of pregnancy and eclampsia, there is an over-production of the hormones of the posterior pituitary gland. It is probable that this is the factor which prevents atony of the urinary tract in these cases.

---

* The Bradshaw lecture delivered before the Royal College of Physicians of London on Nov. 1st.

FIG. 1



Urinary tracts in a 5-para, who died undelivered of placenta prævia at term, and in whom the urine was sterile.

MICROSCOPICAL EXAMINATION

The striking microscopical feature in the lower part of the ureter during pregnancy, as was first demonstrated by Hofbauer, is the excessive hypertrophy of the ureteral sheath, which in the non-pregnant state is a very thin structure. The individual muscle bundles are hypertrophied and there is a proliferation of fibrous tissue between them, converting the ureter into a rigid tube. The same changes are also seen in the wall of the ureter. They are found to the most marked degree in the juxtavesical portion but also to a less extent higher up the ureter. Both ureters are affected and primigravidæ as much as multiparæ. The amount of hypertrophy varies greatly in different cases and does not always correspond to the amount of dilatation present. It was absent in the cases who had died in the early months of pregnancy. Transverse sections of dilated ureters at the widest part show little evidence of hypertrophy, the wall being thinned out and the muscle-fibres stretched.

Even where there is marked dilatation of the kidney pelvis and calyces on one side only, no microscopic difference has been detected between the two kidneys, although from tests on the living a similar degree of dilatation appears to have a definite effect on function.

It appears therefore that, in the later months of pregnancy, the right ureter is frequently obstructed at the pelvic brim. A careful examination in women who have died undelivered or in the living before performing Cæsarean section shows that the ureter can be compressed between the uterus and the psoas muscle on the right side. In some cases the compression seems to be between the uterus and the common iliac artery which on the right side, as it has to cross the vertebral column, lies more anteriorly than on the left and pushes the ureter forwards. At Cæsarean section, flexing the thigh to relax the psoas muscle relieves the compression of the ureter to some extent. This may explain the partial relief of pain experienced by some pregnant women on flexing the thigh. On the left side the ureter is less exposed to pressure for several reasons. In the first place, because of the difference in the course of the common iliac vessels on the two sides, it lies more posteriorly on the left and, instead of crossing the vessels almost at right angles as on the right side, it runs almost parallel to them. It is therefore partly protected from pressure at the pelvic brim by the promontory of the sacrum. Secondly, the left ureter at the pelvic brim passes behind the sigmoid colon and its mesentery. The peristalsis of the bowel makes any pressure on the left ureter intermittent and may directly stimulate ureteral peristalsis. I think these anatomical observations explain the difference on the two sides in the second half of pregnancy. Hofbauer is of the opinion that the hyperplasia of the lower ends of the ureters causes the dilatation and, in support of this, he states that pyelograms taken post partum show that the dilatation does not stop short at the pelvic brim but extends down to the bladder. He explains the difference on the two sides as due to the dextro-rotation of the uterus during pregnancy, kinking the rigid lower end of the right ureter while the left is merely put on the stretch. I have found at Cæsarean section that the uterus is sometimes twisted to the left and that in these patients the dilatation is not more marked on the left side. Considerable dilatation of the urinary tract may be present between the fourth and fifth months, when the proliferative changes are very slight. It seems more likely that the changes described are in the nature of a protective mechanism to prevent undue compression of the lumen of the ureter by the descending head. Further, in the non-pregnant state ovarian cysts can be shown to cause dilatation of the ureters. Comparing the dilatation in the later months of pregnancy with that produced by an ovarian cyst of the same size and in the same position, we find that it is much less in the latter and accompanied by very little atony. As the cyst is usually situated to one side, it causes dilatation of the ureter on that side. If the cyst is so large as to cause uniform pressure in all directions, the right ureter is always more affected than the left. This is illustrated in Fig. 2, which is an intravenous pyelogram from such a case. The right urinary tract will be seen to be dilated from the pelvic brim upwards but there is complete absence of kinks of the ureter and chromocystoscopy shows very little atony, although there is delay in the appearance of the indigo-carmine. The right ureter is therefore more liable to pressure than the left in both the non-pregnant and pregnant states. This is due, in all probability, to the different course of the two ureters as they cross the pelvic brim and not to the uterus twisting to the right.

Urological Examination

The *methods* employed comprise cystoscopy, chromocystoscopy, pyelography, and separate kidney function tests.

Chromocystoscopy is particularly useful in pregnancy, for generally there is an absence of vigour in the ureteral peristalsis which makes the efflux difficult to see unless stained by dye. Delay in appearance of the dye, which is in good concentration when it does appear, suggests atony of the ureter without dilatation or kidney damage. Poor concentration of the dye suggests either kidney damage or marked dilution of the dye in a dilated urinary tract. If due to kidney damage alone the indigo-carmine excretion time will be within normal limits, but the dye will not reach satisfactory concentration. If due to dilution alone, there will be a steady improvement in the concentration of the indigo-carmine after its first appearance, and there will be a characteristic variability in the size of the efflux. If dilatation is accompanied by atony, as is common during pregnancy, the ureteral action is much more irregular. There is great variation in the size of the efflux, and long periods of rest are followed by periods of great activity when contractions follow one another at very short intervals; so that there may be great variation in the same case in the indigo-carmine excretion time, depending on whether the dye is given during a period of rest or one of activity.

Intravenous pyelography has great advantages over the older one of retrograde pyelography. Firstly, artificial distortion of the urinary tract and any risk which may be attached to ureteral catheterisation are avoided. Secondly, the time of appearance of the shadow of the renal pelvis gives us valuable information about kidney function and the relative efficiency of the two sides. In the normal non-pregnant state it is difficult to obtain satisfactory shadows of the ureters by this method but during pregnancy the stasis in the ureter is usually sufficient to obviate this difficulty. Intravenous pyeloscopy is unsatisfactory during pregnancy, owing to the thick abdominal wall and to the relatively faint shadow obtained, but by combining the results of chromocystoscopy and pyelography, the various changes in the structure and function of the urinary tract in pregnancy can be deduced. Pyelograms are taken at intervals after the intravenous injection of uroselectan or abrodil.

Kidney function tests.—A complete urea-concentration test on separate kidneys is not possible during pregnancy, because catheters cannot be left in during the whole course of such a test, as if inserted above the pelvic brim the natural state of the urinary tract is interfered with and if below they cannot cope with the intermittent emptying of the dilated tract so that urine escapes past them. Information regarding the kidney's power to concentrate urea has to be obtained from isolated specimens.

An analysis of 100 cases (including normal pregnancies and various complications except infection) examined once during the pregnancy and 66 cases (all normal pregnancies) examined at monthly intervals during pregnancy shows that from the fourth month onwards, especially in primigravidæ, there is a definite delay in excretion, due either to atony alone or to atony accompanied by dilatation. Table II. is an analysis of the 66 cases examined at monthly intervals.

TABLE II

Months pregnant.	Primigravidæ.		Multiparæ.	
	Right.	Left.	Right.	Left.
Over 2 ..	5 mins.	4·3 mins.	4·1 mins.	4·0 mins.
„ 3 ..	4 „	4·6 „	5·4 „	4·5 „
„ 4 ..	8 „	6·0 „	6·8 „	4·2 „
„ 5 ..	11·4 + „	6·0 „	6·7 „	4·3 „
„ 6 ..	11·4 + „	6·5 „	5·7 „	4·5 „
„ 7 ..	10·4 + „	6·3 „	7·0 „	5·0 „
„ 8 ..	7·6 + „	5·0 „	6·7 „	5·0 „

The numbers represent the indigo-carmine time in minutes. + indicates that in several of the cases the dye had not appeared at the end of the observation period.

As already stated, the indigo-carmine excretion time alone may be misleading, so that the actual times shown on the Table must not be taken literally. It will be seen that in primigravidæ the delay in excretion begins at the fourth month, reaches a maximum at the fifth and sixth months, and diminishes towards term. The delay is more marked on the right side. In multiparæ, this Table shows slight delay at the right side but no definite maximum period, and on the left side there is a striking absence of delay in excretion at any stage of pregnancy.

Table III. is an analysis of 37 cases, 16 primigravidæ and 21 multiparæ, selected because of excellent general health and past history, who were examined at monthly intervals during pregnancy. There was some degree of dilatation in 62·5 per cent. of the primigravidæ as compared with 42·8 per cent. of the multiparæ, in whom the dilatation was usually slight. Delay in excretion, like dilatation of the urinary tract, is more frequent and more pronounced in primigravidæ.

TABLE III

Delay.	Primigravidæ.	Multiparæ.
Marked	3 }	3 }
Moderate ..	5 } 62·5 %	0 } 42·8 %
Slight	2 }	6 }
None	6	12

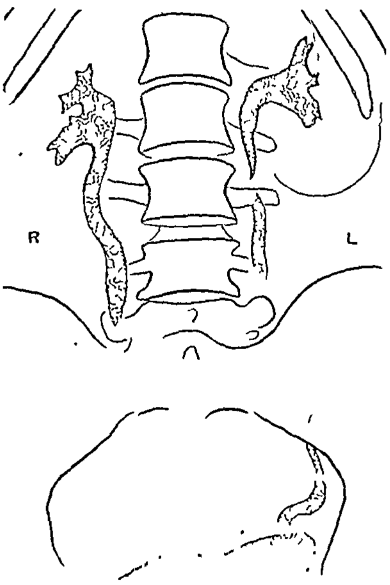
Where the delay in excretion is moderate, a catheter passed into the right ureter after the dye has appeared from the left ureteral orifice will tap the dye as soon as it passes the pelvic brim. Where the delay in excretion is very marked, a catheter passed into the right kidney pelvis will drain urine still unstained by indigo-carmine. If the upper urinary tract is drained by introducing a catheter to a point above the pelvic brim for some minutes before injecting the dye, the excretion time is markedly improved. The site of the obstruction to outflow, which is the cause of the back-pressure on the kidney susbtance, is therefore at the pelvic brim.

As has been pointed out in the examination of post-mortem specimens, the dilatation usually affects, on the right side, the kidney pelvis and calyces as well as the ureter, whereas, on the left side, it is more often confined to the ureter. Intravenous pyelograms show this to be the case in the living. Where there is considerable dilatation of the calyces, there is also delay in appearance of the shadow, indicating delay in excretion through the kidney substance, that is, interference with kidney function. In such a case there is usually also a further delay in appearance of the shadow of the kidney pelvis and ureter, indicating stasis in the urinary tract. The left urinary tract may show right down to the pelvic brim, while on the right side the calyces are only beginning to appear. In the absence of infection, there may be marked dilatation of the calyces with only slight delay in excretion through the kidney substance, whereas, in cases of pyelitis of pregnancy, there may be little dilatation of the calyces present with very marked delay in excretion through the kidney substance. Many of those cases then are probably pyelonephritis and not simply pyelitis.

The urea-concentration test adds information regarding the effect of this dilatation on kidney function. If during a urea-concentration test urine is taken during the second hour from either kidney, the concentration of urea on the left, relatively undilated side, is always higher than on the dilated right side, while one hour later the urea concentration on the left side has fallen and is lower than that on the right side which has increased, although it usually will not reach the maximum attained on the left side. In individual cases the results vary a great deal according to the time at which the specimens are taken and need care in interpretation. The delay in the concentration of urea by the right kidney in pregnancy is demonstrated in the examination of separate kidney specimens in 21 out-patients, in whom, although the indigo-carmine test showed the left kidney to be more efficient than the right, the urea concentration was higher on the right side than on the left in seven cases.

The usual sequence of events in pregnancy is as follows. At the beginning of pregnancy a primary atony of the ureters occurs. In some this is very slight and may be scarcely appreciable. In others it affects both ureters, equally in primigravidæ but in multiparæ it may be more pronounced on one side, usually the right, where presumably there has been a previous dilatation of a marked degree. At the third month the primary atony disappears. At the fourth to the fifth month delay in excretion occurs, usually most marked on the right side. At this stage the delay may be due to atony without dilatation but, more commonly, dilatation of the ureter above the pelvic brim can be demonstrated. The degree of stasis is not in proportion to the amount of dilatation present, as considerable *dilatation may be present* without any stasis. In some cases spasm of the ureter at the pelvic brim can be demonstrated at this stage, causing severe spasmodic pain over McBurney's point. In such cases there is marked activity of the urinary tract but delay in excretion occurs due to the spasm, and there is dilatation and kinking of the ureter above the site of the spasm. Where dilatation is accompanied by atony, pain is usually absent but, if present, is slight and of a dull aching character. The spasm of the ureter is probably the result of the pressure of the uterus, as it can be produced by an ovarian tumour of the same size. The stasis and dilatation become more pronounced until they reach a maximum usually at the sixth month. *From then until term elimination slowly* improves. On the left side, where the delay usually has been less marked, this improvement, which may be accompanied by a decrease in the amount of dilatation, is easily seen, but on the right side, when there has been very marked stasis and dilatation, there are technical difficulties in the way of *appreciating* moderate degrees of improvement. Within a very short time after delivery the ureters again show atony, although the excretion time may be improved. The following cases illustrate the various changes occurring in the *urinary tract*, *in* pregnancy which have been discussed above.

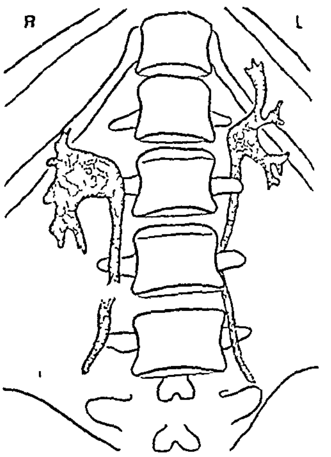
FIG. 3



CASE 1.—Mrs. A., a primigravida. At two and a half months delay in excretion of dye and evidence
of atony. Intravenous pyel
both ureters. At three and
culty in obtaining a pyelogr
function. At four and a
and a similar pyelogram obtained as at two and a half months. At six months developed a right-sided pyelitis, pain only slight. At seven months on left side indigo-carmine excretion time is now normal, although in pyelogram the left ureter is still dilated; right urinary tract more dilated from pelvic brim upwards (see Fig. 4).

CASE 2.—Mrs. B., 2-para. At three and a half months atony of ureters, but very little delay in excretion of dye. *At five and a half months marked delay in excretion of* dye with irregular action of ureters due to atopy. Intravenous pyelograms, taken at 5 and 20 minutes after injection, are seen in Figs. 5 and 6. Fig. 5 shows both renal tracts apparently normal, whereas Fig. 6 shows them markedly dilated. *The second plate was taken just before the ureters* emptied. The indigo-carmine excretion tests had previously shown that the quiescent period on each side was about 20 minutes. At term indigo-carmine excretion time at the left side normal, but marked delay at the right. Intravenous pyelogram (Fig. 7) *shows the left urinary* tract to be much less dilated than it was at five and a half months (Fig. 6), while the right is more dilated, with delay in excretion through the kidney which was not present at five and a half months.

FIG. 5



CASE 3.—Mrs. C., 3-para. At six and a half months indigo-carmine excretion time on both sides was six minutes and the action of the right ureter is regular although, as is seen in Fig. 8, it is markedly dilated and kinked.

CASE 4.—Mrs. D., primigravida. At three and a half months sudden severe pain over appendix region. Fig 9 shows the intravenous pyelogram taken *50 minutes after* injection. There is spasm of the right ureter at the pelvic brim. The ureteral catheter could not be inserted beyond this point. In the previous plate at 30 minutes the uroselectan had not reached the ureter on the right side, while the left ureter showed distinctly on the plate taken at seven minutes.

Infection

Although stasis can occur in the urinary tract in pregnancy without infection, a clinical study shows that there is a close relationship between the time of onset of stasis and the time of onset of infection, the so-called pyelitis of pregnancy. This is well illustrated in Table IV. In primigravidæ the time

TABLE IV

—	Under 3 mths.	3–4 mths.	4–5 mths.	5–6 mths.	6–7 mths.	7 + mths.	No definite time of onset.
			70 %				
Primigravidæ	8	1	50	33	9	13	4
Multiparæ ..	30	17	28	34	36	28	23
			31 %				

of onset of infection is remarkably constant, 70 per *cent. occurring* between the fourth and sixth months of pregnancy, whereas in multiparæ the time of onset is much more variable. As has already been shown, this is also the case for the time of onset of stasis. In 6 of the 8 primigravidæ and 17 of the 30 multiparæ, in whom the symptoms of infection appeared at or before the third month, a history of previous infection was obtained. In these cases the primary atony, described above, was probably responsible for the lighting-up of the previous infection at this early stage of the pregnancy.

As *the stasis is more* marked in primigravidæ one would expect the infection to be more severe, and this is found to be the case. In a large series the incidence of premature delivery, either spontaneous or induced, was twice as high in primigravidæ.

INCIDENCE OF INFECTION

It is difficult to obtain figures to determine the risk of infection of the urinary tract in pregnancy in previously healthy women. Of 135 women who had a catheter specimen of urine examined at monthly intervals during the pregnancy, 96 had sterile urines at the first visit in the second month of pregnancy and of these, 14, or 14·5 per cent., developed pus and organisms in the urine at one time or another during the pregnancy, 6 of these had symptoms suggesting pyelitis, 2 cystitis, and the rest, in whom infection was slight and transient, had no symptoms. The relative frequency of pyelitis of pregnancy in the antenatal wards of a maternity hospital can be readily determined and is shown in Table V. The first column represents the incidence of the various complications in 1000 consecutive cases, admitted over a period of three years to the antenatal wards of one unit of the Glasgow Royal Maternity Hospital, representing a third of the total admissions to the antenatal department, so that numerically it corresponds to a single year for the whole hospital. The figures for my series indicate that pyelitis is one of the most frequent complications of pregnancy, reaching the high figure of 15·6 per cent., whereas the official report estimates the incidence at half this figure, and indeed before 1928 it was diagnosed so infrequently as to be classed with the miscellaneous group of complications. The figures for the other complications, except albuminuria, agree fairly closely in the two series and the explanation of the disparity is probably faulty diagnosis. In my series only 63, or 40 per cent., of the pyelitis cases were correctly diagnosed before admission. The various diagnoses were as follows:—

TABLE V

—	My series of 1000 cases.	Annual hospital reports.				
	1928–29–30	1926	1927	1928	1929	1930

FIGS. 2 4 6

CLINICAL FEATURES OF INFECTION

In the absence of urinary symptoms and where the toxæmic symptoms are predominant, the condition is very liable to be wrongly diagnosed as albuminuria or hyperemesis. A microscopical examination of the urine should always be done as a routine measure in the diagnosis of any toxæmia of pregnancy. It is difficult to see why pyelitis should be wrongly diagnosed so often as albuminuria, as the latter is characterised by œdema, rise in blood pressure, and albumin in the urine and no pus, while in pyelitis there is never any œdema or rise of blood pressure (which may, in fact, be lowered), and seldom more than a faint trace of albumin.

Pain and tenderness referable to the urinary tract may be very misleading, as severe infection may be present without either, or both without infection. Classifying the 156 cases of pyelitis in the 1000 series accurately according to the pain distribution, the incidence of infection on the two sides is found to be right side 76, left side 25, bilateral 36, while 19 were toxic or latent. As a test 30 cases were examined urologically to compare the clinical diagnosis with the urological findings, with the following results. Thirteen were diagnosed clinically as right-sided, but urologically only four were right-sided, the rest being bilateral. Six were clinically left-sided, and urologically all were bilateral. Eleven were clinically bilateral, and urologically only eight of these were bilateral, the other three having right-sided infection only, pain and tenderness being present on the left side without infection. Clinically, then, the infection is diagnosed as bilateral in only 36 per cent. of cases, whereas actually, as proved by urological examination, it was bilateral in 76 per cent. Pyelograms of infected cases offer a possible explanation of the variable clinical findings.

In a typical attack of acute pyelitis of pregnancy with marked pain and tenderness there is only a moderate degree of dilatation of the ureters and kidney pelves. Kinks of the ureter are found either at the junction of the ureter and kidney pelvis, in which case the ureter may not open into the most dependent part of the kidney pelvis or at the junction of the upper and middle thirds of the ureter. The distribution of the pain corresponds to the situation of the kinks, and the pain is probably due to spasm set up at these points by the partial blockage. As the pain is instantly relieved by passing a catheter to a point immediately above the pelvic brim, the blockage and spasm in the upper part of the ureter must be dependent on obstruction at the pelvic brim. This is illustrated in Fig. 10.

This is an intravenous pyelogram of a 3-para, five and a half months pregnant, suffering from acute pyelitis. Although her severe pain was confined to the right kidney region, the insertion of a catheter to a point just above the pelvic brim caused the pain to disappear almost at once, and leaving the catheter in this position for two days was followed by rapid improvement in the patient's general condition and by an immediate fall in the temperature and pulse-rate.

Besides relieving the pain and acute blockage in the urinary tract in such a case, drainage by a catheter in this position also improves the function of the kidney, as is illustrated by the following experiment.

Mrs. E., 3-para, a case of bilateral pyelitis, had an intravenous pyelogram taken at four months, when a five-minute plate showed no shadow on either side. A 20-minute plate showed gross dilatation of both urinary tracts with delay more marked on the left side (Fig. 11). The X ray examination was repeated, and on this occasion the kidney pelves were drained for two hours by ureteral catheters before injecting the uroselectan. As will be seen in Fig. 12, a dense shadow of the calyces on the right side and a faint shadow on the left side showed in a five-minute plate.

If infection supervenes in a urinary tract which is already markedly dilated, the symptoms are seldom acute, although there may be a remittent fever. The pain is transitory and dull and aching in character. In this type of case lack of drainage due to stasis leads to toxic absorption with symptoms of nausea and vomiting, emaciation, and anæmia. This is the type of case which is often undiagnosed. Fig. 13 is an intravenous pyelogram from such a case.

This is a case of bilateral pyelitis in a multipara, who on admission had no symptoms referable to the urinary tract and showed marked toxæmia. This pyelogram was taken one and a half hours after the injection of uroselectan, as it was only then that a satisfactory picture of the left urinary tract could be obtained. The kidney function on the right side was so poor that no shadow was obtained, even after this long interval.

Where the urinary tract is completely atonic, pain is absent although infection may be so severe that there is almost complete interruption of kidney function. Cases have been encountered which, although the pain and tenderness were present only on the left side, the condition on that side was much *less severe than on the right,* where solid pus was evacuated from the kidney pelvis.

A careful history usually elicits the fact that earlier in the illness pain and tenderness were present on the right side also. Presumably the pain has disappeared as the tone of the urinary tract has been destroyed, for the pus lodging in the urinary tract aggravates the existing atony and if it is not evacuated by some means or other, the tract quickly beco quite atonic. Infection can exist where there is very little stasis, as often happens on the left side. The greater degree of stasis on the right side explains why, although the infection is usually bilateral, it is more severe on that side.

The condition is probably a pyelonephritis in th cases where the toxæmia is profound, with sickn jaundice, and prostration the prominent features, at post-mortem examination abscesses have b found in the kidney substance of patients who a history of this type. How far the kidney substa is involved in the less severe cases is difficult to

re is ly marked interference with ki

e infection is confined to the ri

of urea on that side is alw

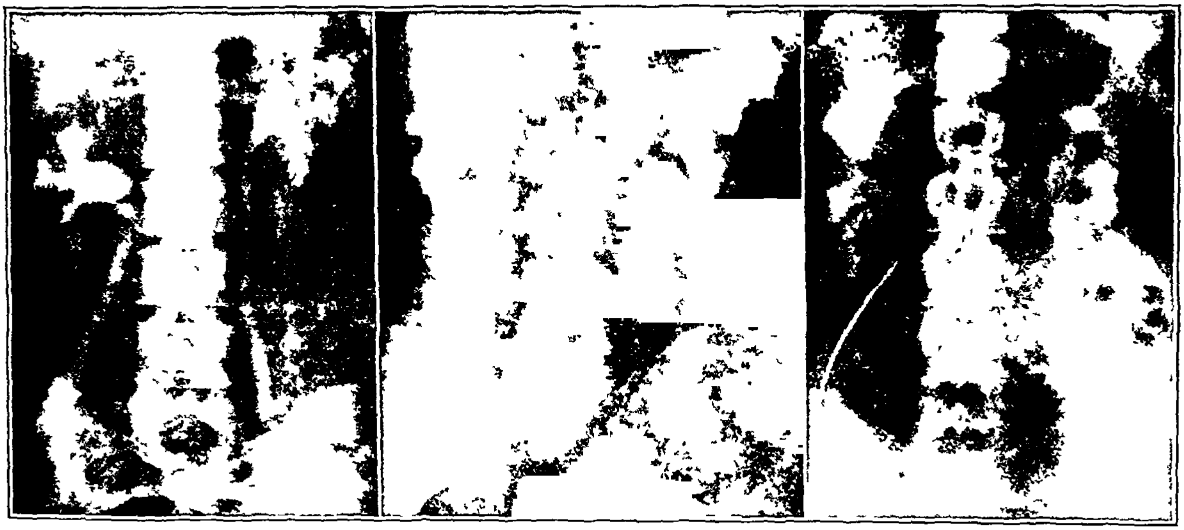
FIGS. 7

8

9

very much lower than on the non-infected side, but a total bladder urea-concentration test is within normal limits. In 19 cases with moderately severe bilateral infection, a MacLean's urea-concentration test was done. The maximum concentration of urea, which was always delayed until at least the third hour, was under 2 per cent. except in one case. These points have a definite bearing on prognosis and treatment.

FIGS. 10 11 12



Treatment

The routine treatment of pyelitis of pregnancy in hospital consists of confining the patient to bed and giving if possible at least five pints of fluid in 24 hours, along with large doses of alkalis, until the urine is alkaline. In most cases under this treatment the acute symptoms subside. Light diet is then allowed and the patient is given urinary antiseptics till the end of pregnancy. Under this treatment however the urine practically never becomes sterile before the end of pregnancy and of 104 cases who were traced to the end of pregnancy out of 156 consecutive cases of pyelitis admitted, 34, or 32·6 per cent., did not go to term. Apart altogether from any consideration of after-results this treatment is only partly successful from the point of view of the pregnancy. Of the 34 patients who did not go to term 3 died (in one cardiac disease was probably the primary cause of death). In 5 cases labour was induced and 11 went into labour spontaneously before the seventh month. Eleven went into labour between the seventh and eighth months and 7 in the last month of pregnancy. It will be seen therefore that there is urgent need of earlier and more efficient treatment. Recently Crabtree and Prather [7] in an experience of treatment of pyelitis extending over ten years have found that raising the fluid intake to a maximum is the most important single factor and, if efficiently carried out, enables the patient to go to term without hospital treatment. The value of this treatment can be demonstrated by withholding fluids, when within a few hours an exacerbation of the symptoms will occur.

Posture plays a part. As already stated, at Cæsarean section operations it has been observed that flexion of the thigh causes relaxation of the psoas muscle, thereby diminishing the pressure on the ureter at the pelvic brim. Many patients suffering from pyelitis state that they feel much more comfortable when they draw up the knees and that they do not like the dorsal decubitus. Improvement in many cases, occasionally striking, has been observed by placing the patient on the hands and knees at frequent intervals, especially if this is accompanied by massage over the kidney regions and along the course of the ureters. As seen in chromocystoscopy, the massage stimulates the atonic ureters to contract. Elevation of the foot of the bed so that the ureters are acting against gravity has been found to cause an exacerbation of the symptoms where the tone is poor.

In certain cases a high fluid intake is impossible owing to persistent vomiting, brought about either by the very severe pain of an acute attack or by toxæmia in a neglected or inefficiently treated case. In such cases the improvement in the patient's condition can be most speedily brought about by renal lavage. A careful urological examination is made, including chromocystoscopy and catheterisation of the ureters, to arrive at an exact diagnosis and prognosis. (There seems to be little danger in this procedure. In 80 cases of pyelitis where catheters were passed to one or both kidneys only 2 showed any reactionary rise of temperature.) Renal lavage can be carried out at the same time. In *seriously* ill patients it has been found that a single renal lavage is not sufficient to bring down the temperature and pulse-rate, and in such cases indwelling catheters are much more effective. If the acute symptoms do not subside on the routine treatment of fluids and alkalis within a few days, or in a less acute case, if the pain and sickness persist so that the patient cannot rest or take sufficient fluid, then an indwelling catheter is inserted. If in a more chronic case there is debility, lack of appetite, loss of weight, and low fever an indwelling catheter is used. In an analysis of the results of treatment by indwelling catheter, in 38 cases improvement is assessed as being very marked, when it was so striking as completely to alter both the clinical picture and the prognosis. Twenty-three cases come into this category. Two of these were untraced and the remaining 21 patients were all able to carry on the pregnancy beyond the thirty-sixth week and were delivered of live children. They all made good recoveries. This is very satisfactory as clinically bilateral, and urologically only eight of these were bilateral, the other three having right-sided infection only, pain and tenderness being present on the left side without infection. Clinically, then, the infection is diagnosed as bilateral in only 36 per cent. of cases, whereas actually, as proved by urological examination, it was bilateral in 76 per cent. Pyelograms of infected cases offer a possible explanation of the variable clinical findings.

In a typical attack of acute pyelitis of pregnancy with marked pain and tenderness there is only a moderate degree of dilatation of the ureters and kidney pelves. Kinks of the ureter are found either at the junction of the ureter and kidney pelvis, in which case the ureter may not open into the most dependent part of the kidney pelvis or at the junction of the upper and middle thirds of the ureter. The distribution of the pain corresponds to the situation of the kinks, and the pain is probably due to spasm set up at these points by the partial blockage. As the pain is instantly relieved by passing a catheter to a point immediately above the pelvic brim, the blockage and spasm in the upper part of the ureter must be dependent on obstruction at the pelvic brim. This is illustrated in Fig. 10.

This is an intravenous pyelogram of a 3-para, five and a half months pregnant, suffering from acute pyelitis. Although her severe pain was confined to the right kidney region, the insertion of a catheter to a point just above the pelvic brim caused the pain to disappear almost at once, and leaving the catheter in this position for two days was followed by rapid improvement in the patient's general condition and by an immediate fall in the temperature and pulse-rate.

Besides relieving the pain and acute blockage in the urinary tract in such a case, drainage by a catheter in this position also improves the function of the kidney, as is illustrated by the following experiment.

Mrs. E., 3-para, a case of bilateral pyelitis, had an intravenous pyelogram taken at four months, when a five-minute plate showed no shadow on either side. A 20-minute plate showed gross dilatation of both urinary tracts with delay more marked on the left side (Fig. 11). The X ray examination was repeated, and on this occasion the kidney pelves were drained for two hours by ureteral catheters before injecting the uroselectan. As will be seen in Fig. 12, a dense shadow of the calyces on the right side and a faint shadow on the left side showed in a five-minute plate.

If infection supervenes in a urinary tract which is already markedly dilated, the symptoms are seldom acute, although there may be a remittent fever. The pain is transitory and dull and aching in character. In this type of case lack of drainage due to stasis leads to toxic absorption with symptoms of nausea and vomiting, emaciation, and anæmia. This is the type of case which is often undiagnosed. Fig. 13 is an intravenous pyelogram from such a case.

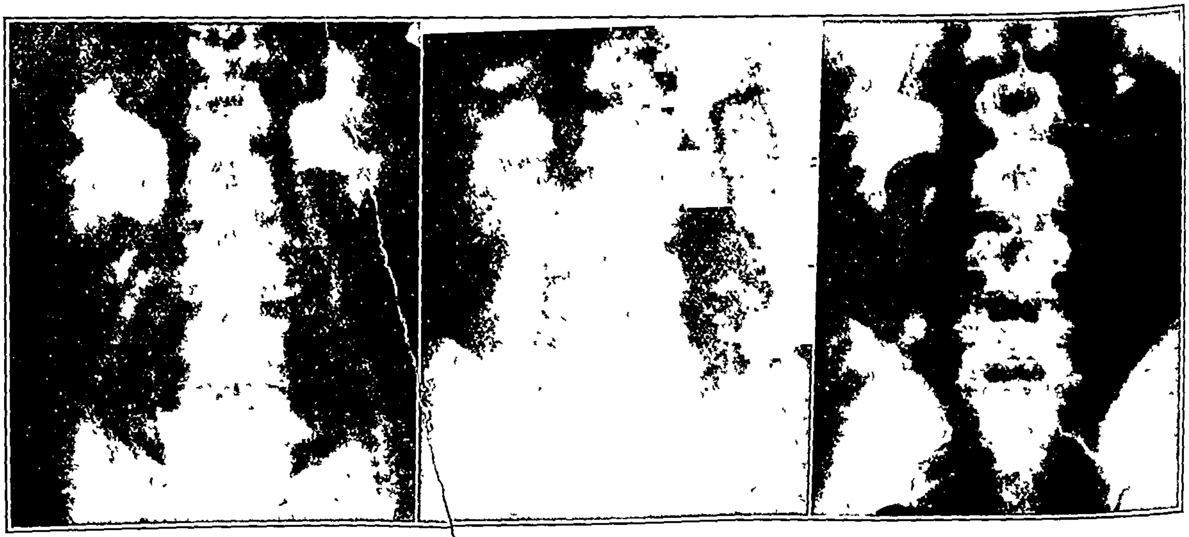
This is a case of bilateral pyelitis in a multipara, who on admission had no symptoms referable to the urinary tract and showed marked toxæmia. This pyelogram was taken one and a half hours after the injection of uroselectan, as it was only then that a satisfactory picture of the left urinary tract could be obtained. The kidney function on the right side was so poor that no shadow was obtained, even after this long interval.

Where the urinary tract is completely atonic, pain is absent although infection may be so severe that there is almost complete interruption of kidney function. Cases have been encountered where, although the pain and tenderness were present only on the left side, the condition on that side was much less severe than on the right, where solid pus was evacuated from the kidney pelvis.

A careful history usually elicits the fact that earlier in the illness pain and tenderness were present on the right side also. Presumably the pain has disappeared as the tone of the urinary tract has been destroyed, for the pus lodging in the urinary tract aggravates the existing atony and if it is not evacuated by some means or other, the tract quickly becomes quite atonic. Infection can exist where there is very little stasis, as often happens on the left side. The greater degree of stasis on the right side explains why, although the infection is usually bilateral, it is more severe on that side.

The condition is probably a pyelonephritis in those cases where the toxæmia is profound, with sickness, jaundice, and prostration the prominent features, as at post-mortem examination abscesses have been found in the kidney substance of patients who had a history of this type. How far the kidney substance is involved in the less severe cases is difficult to say, but there is certainly marked interference with kidney function. Where the infection is confined to the right side, the concentration of urea on that side is always

FIGS. 7 8 9



diet which contained C. 250 g., P. 70 g., F. 50 g., ls. 1577. Adlersberg[8] has used a similar diet, but sometimes gave a high protein ration in addition. In this country, at a meeting of the Royal Society Medicine (Section of Therapeutics and Pharma- logy) in 1931,[9] Poulton, Hunt, Lawrence, Nixon, hompson, Graham, Cammidge, and Weiss all agreed at patients did better with an increased rbohydrate ration, and Nixon, Graham, d Cammidge laid stress on the importance reducing the amount of fat in the diet. cently Nixon[10] and Dyke[11] have pub- hed papers on the same subject. Very ferent diets are being used, apparently th excellent results, the only common tor being the high carbohydrate.

At the meeting referred to above, one us (G. G.) gave the results of observa- n on 15 "pedigree" patients, who had been in St. Bartholomew's Hospital ore the end of 1924. They had, with exception, attended the "follow-up" partment regularly monthly or three- nthly, and had adhered fairly closely the authorised diet of about C. 40–50 g., 70 g., F. 125–150 g., Cals. 1613–1846. ey were examined again before Decem- , 1929; during the six years since their charge from hospital they had kept well l were earning their living, although a inite increase in the insulin require- nts had occurred. In January, 1930, amount of fat was reduced to about g. and the carbohydrate was dually increased by 10 or 15 g. to g., the protein being left unchanged at about g. The insulin dosage was at first increased in proportion of 1 unit of insulin to 2 g. of carbo- rate, but as definite signs of overdose often urred the later increases were made in the propor- of 1 unit to 4 g. of carbohydrate. A year after increase in the carbohydrate was begun, four of the 15 patients needed 2 or 3 units less, in e of the increase of 40 to 60 g. in the carbohydrate on; two required the same amount of insulin; r required 6 or 8 more units; two required 11 12, while three required 18 and 20 more units. ring the year 1931 the carbohydrate was increased a further 10 to 40 g., except in three cases where was kept unchanged. At the end of 1931 all the four patients who had reduced their insulin in the first year had made further decreases in the insulin; and three others were also taking less insulin than in 1929. The actual decreases varied from 6 to 32 units (Table I., see Figure). The two patients who had not altered their dose in 1930 were still taking the same amount of insulin, although the carbohydrate had been increased by 10 and 15 g. One patient, a boy of 19, had reduced his insulin by 20 units, and was therefore taking the same amount of insulin as in 1929, although the carbohydrate consumed was 84 g. more; two other patients had made no change, and two patients had increased their insulin by 8 and 9 units respectively. The results were so striking that another 40 patients, whose diets are fairly accurately known, have been examined. The carbohydrate had been increased by 46 to 99 g., and varied between 100 and 145 g. This batch of patients has now been under observation between eight and 28 months; 14 take less insulin than before the increase of carbohydrate; two take the same amount of insulin; seven take 2 to 8 more units; ten take 10 to 19 more units; and seven take 20 to 30 more units (Table II.). Many of these patients seem to be still improving.

This Figure indicates the change in the number of units of insulin needed for each of the cases mentioned in Table I. in December, 1930 and 1931, showing the increase or decrease following initiation of a higher carbohydrate diet in December, 1929.

An attempt was made in this series to discover whether the severe or the mild cases improved most. The severity of the disease was measured by the C/I ratio, described by one of us (H. E. W. R.).[12] The total amount of carbohydrate in the diet, together with 60 per cent. of the protein and 10 per cent. of the fat was added together, and the sum divided by the units of insulin—e.g., a diet consisting of C. 100, P. 70, F. 100 has a total carbohydrate value of $100+42+10=152$. If the insulin dosage was 50 units, the C/I ratio would be $152/50=3{\cdot}04$.

One defect of this method is the difficulty of ascertaining in out-patients whether the dose of insulin is adequate. If the insulin dosage is inadequate to keep the urine sugar-free, the C/I ratio will convey the impression that the diabetic condition is less severe than *it actually* is. The blood-sugar in our cases is estimated every 4 to 12 weeks, between the hours of 10.30 and 12 noon, after the usual breakfast and insulin. The dose of insulin is assumed they are all patients who did not respond to the routine treatment. Eleven cases showed *partial improvement*. Of these, seven were improving in any case and the process was only accelerated by the drainage. Two were very ill and the improvement was not considered sufficiently dramatic to allow of delay in terminating the pregnancy. Two went into labour within a few hours of the insertion of the catheter. In four cases there was *no improvement*. In two of these it was probably due to abscess formation in the kidney before treatment was adopted. Both died and in one this was substantiated at post-mortem examination. Permission for post-mortem examination was refused in the other case. Two were definitely worse after catheterisation, but as these were among the first cases to be treated by me by this method, the failure may have been due to faulty technique.

FIG. 13

The two patients who went into labour following catheterisation were both in the last month of pregnancy, at which stage of pregnancy I have found that distension of the renal pelvis sufficient to cause colic is associated with the onset of uterine contractions. Similarly, in acute pyelitis, renal colic may be so severe as to initiate uterine contractions and cause a miscarriage even as early as the sixth month. If the renal colic in such a case is relieved by the passage of a ureteral catheter, the uterine contractions subside.

Termination of the pregnancy, either induced or spontaneous, is followed by a rapid improvement. As the passage of a catheter to a point above the pelvic brim has the same effect, the cause of the improvement in both instances is probably the relief of the compression of the ureter at the pelvic brim. The beneficial effect of the catheter remains after its withdrawal as the relief of tension probably enables the ureter to regain its tone and the increased intake of fluid made possible by the improved general condition of the patient stimulates ureteral peristalsis.

Summary

(1) Pregnant women show varying degrees of atony of the upper urinary tract. In some this is very slight so that no appreciable stasis is produced. In others it is very marked and can be shown to occur at the very beginning of pregnancy. (2) In the second half of pregnancy, dilatation and stasis frequently result and are due to pressure of the uterus on the atonic ureters at the pelvic brim. (3) Dilatation and stasis from the pelvic brim upwards can be produced in the non-pregnant by ovarian cysts. In these the dilatation is less and there is an absence of the marked elongation and kinking of the ureter which is characteristic of pregnancy, even although the pressure exerted by the cyst may be greater than could possibly be exerted by the pregnant uterus. The atony peculiar to pregnancy is therefore the primary factor. (4) In normal pregnancy the tone of the ureters has been shown to improve near term, and in cases of albuminuric toxæmia there is a minimum of atony and stasis. In both instances there is believed to be an excess of posterior pituitary hormone in the blood. The primary factor in the production of the changes in the upper urinary tract in pregnancy is probably, therefore, a disturbance of the endocrines. (5) Infection of the urinary tract is common during pregnancy and is often unrecognised. (6) Infection is always preceded by stasis and seldom clears up completely until the stasis is relieved by termination of the pregnancy. (7) Early diagnosis is most important, as if instituted early, simple treatment by abundant fluids and alkalis is sufficient to enable the patient to go to term. (8) Ureteral catheterisation has a definite place in the treatment of serious cases for the relief of pain and the promotion of drainage.

THE HIGH CARBOHYDRATE DIET IN THE TREATMENT OF DIABETES MELLITUS

By GEORGE GRAHAM, M.D. CAMB., F.R.C.P. LOND.
PHYSICIAN TO OUT-PATIENTS, ST. BARTHOLOMEW'S HOSPITAL

A. CLARK, M.D., M.R.C.P. LOND.
CHIEF ASSISTANT TO A MEDICAL UNIT OF THE HOSPITAL

AND

H. E. W. ROBERTON, M.B. CAMB.
LATE HOUSE PHYSICIAN TO THE HOSPITAL

AN important change has taken place in the last few years in the dietetic treatment of diabetes mellitus. Before the discovery of insulin the diet for a severe case was an extremely restricted one. The carbohydrate ration was very small (30–50 g.); the protein ration was about the same as at present (70 g.); the fat ration was often very large (150–200 g.). Even larger amounts of fat (200–250 g.), with small amounts of protein (20–50 g.) and of carbohydrate (30–40 g.), were advocated by Petren,[1] and Newburgh and Marsh.[2] The diet used by one of us (G. G.)[3] was approximately C. 42 g., P. 65 g., F. 123 g., Cals. 1581.

In 1923, when insulin was still very expensive—25*s*. for 100 units—the diet was at first little altered. The insulin improved the health of the patients to such an extent that there was a tendency to maintain the diet at the same level, even after the cost of insulin had been much reduced. Some workers began to increase the carbohydrate slightly, and in 1926 Sansum, Blatherwick, and Bowden,[5] and in 1929 Geyelin and Mackie,[4] published papers showing that much better results could be obtained if the carbohydrate was very considerably increased and the fat decreased. In 1930 Rabinowitch[6 7] advocated a diet which contained C. 250 g., P. 70 g., F. 50 g., Cals. 1577. Adlersberg [8] has used a similar diet, but he sometimes gave a high protein ration in addition.

In this country, at a meeting of the Royal Society of Medicine (Section of Therapeutics and Pharmacology) in 1931,[9] Poulton, Hunt, Lawrence, Nixon, Thompson, Graham, Cammidge, and Weiss all agreed that patients did better with an increased carbohydrate ration, and Nixon, Graham, and Cammidge laid stress on the importance of reducing the amount of fat in the diet. Recently Nixon [10] and Dyke [11] have published papers on the same subject. Very different diets are being used, apparently with excellent results, the only common factor being the high carbohydrate.

At the meeting referred to above, one of us (G. G.) gave the results of observation on 15 "pedigree" patients, who had all been in St. Bartholomew's Hospital before the end of 1924. They had, with one exception, attended the "follow-up" department regularly monthly or three-monthly, and had adhered fairly closely to the authorised diet of about C. 40–50 g., P. 70 g., F. 125–150 g., Cals. 1613–1846. They were examined again before December, 1929; during the six years since their discharge from hospital they had kept well and were earning their living, although a definite increase in the insulin requirements had occurred. In January, 1930, the amount of fat was reduced to about 100 g. and the carbohydrate was gradually increased by 10 or 15 g. to 100 g., the protein being left unchanged at about 70 g. The insulin dosage was at first increased in the proportion of 1 unit of insulin to 2 g. of carbohydrate, but as definite signs of overdose often occurred the later increases were made in the proportion of 1 unit to 4 g. of carbohydrate. A year after the increase in the carbohydrate was begun, four out of the 15 patients needed 2 or 3 units less, in spite of the increase of 40 to 60 g. in the carbohydrate ration; two required the same amount of insulin; four required 6 or 8 more units; two required 11 and 12, while three required 18 and 20 more units. During the year 1931 the carbohydrate was increased by a further 10 to 40 g., except in three cases where it was kept unchanged. At the end of 1931 all the four patients who had reduced their insulin in the first year had made further decreases in the insulin; and three others were also taking less insulin than in 1929. The actual decreases varied from 6 to 32 units (Table I., see Figure). The two patients who had not altered their dose in 1930 were still taking the same amount of insulin, although the carbohydrate had been increased by 10 and 15 g. One patient, a boy of 19, had reduced his insulin by 20 units, and was therefore taking the same amount of insulin as in 1929, although the carbohydrate consumed was 84 g. more; two other patients had made no change, and two patients had increased their insulin by 8 and 9 units respectively. The results were so striking that another 40 patients, whose diets are fairly accurately known, have been examined. The carbohydrate had been increased by 46 to 99 g., and varied between 100 and 145 g. This batch of patients has now been under observation between eight and 28 months; 14 take less insulin than before the increase of carbohydrate; two take the same amount of insulin; seven take 2 to 8 more units; ten take 10 to 19 more units; and seven take 20 to 30 more units (Table II.). Many of these patients seem to be still improving.

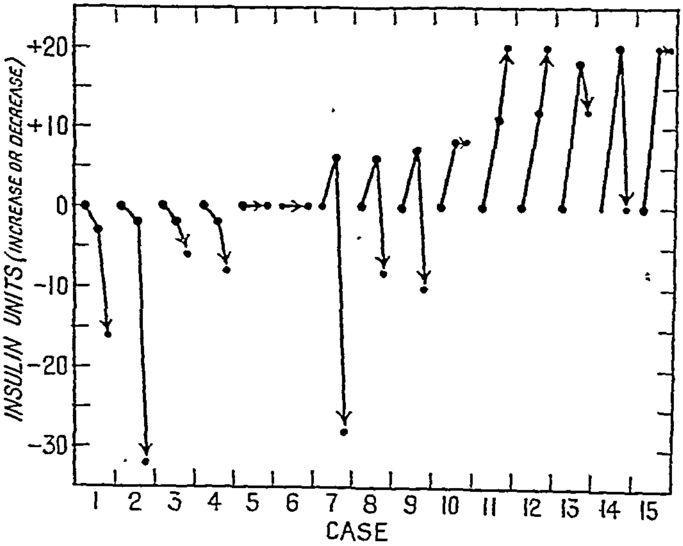
15	17	40	80	120	36	36	44	64	64	−20	−20

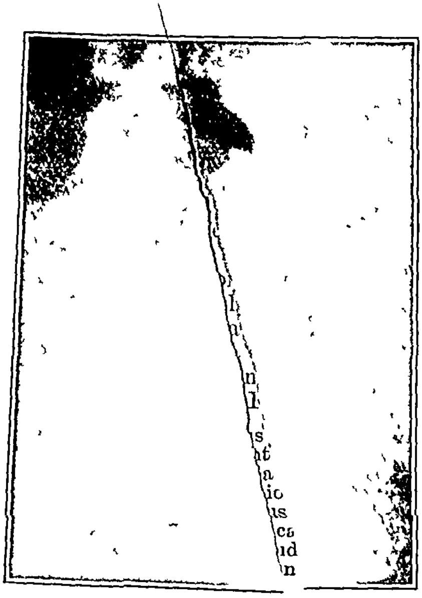


This Figure indicates the change in the number of units of insulin needed for each of the cases mentioned in Table I. in December, 1930 and 1931, showing the increase or decrease following initiation of a higher carbohydrate diet in December, 1929.

An attempt was made in this series to discover whether the severe or the mild cases improved most. The severity of the disease was measured by the C/I ratio, described by one of us (H. E. W. R.).[12] The total amount of carbohydrate in the diet, together with 60 per cent. of the protein and 10 per cent. of the fat was added together, and the sum divided by the units of insulin—e.g., a diet consisting of C. 100, P. 70, F. 100 has a total carbohydrate value of 100+42+10=152. If the insulin dosage was 50 units, the C/I ratio would be 152/50=3·04.

One defect of this method is the difficulty of ascertaining in out-patients whether the dose of insulin is adequate. If the insulin dosage is inadequate to keep the urine sugar-free, the C/I ratio will convey the impression that the diabetic condition is less severe than it actually is. The blood-sugar in our cases is estimated every 4 to 12 weeks, between the hours of 10.30 and 12 noon, after the usual breakfast and insulin. The dose of insulin is assumed they are all patients who did not respond to the routine treatment. Eleven cases showed partial improvement. Of these, seven were improving in any case and the process was only accelerated by the drainage. Two were very ill and the improvement was not considered sufficiently dramatic to allow of delay in terminating the pregnancy. Two went into labour within a few hours of the insertion of the catheter. In four cases there was no improvement. In two of these it was probably due to abscess formation in the kidney before treatment was adopted. Both died and in one this was substantiated at post-mortem examination. Permission for post-mortem examination was refused in the other case. Two were definitely worse after catheterisation, but as these were among the first cases to be treated by me by this method, the failure may have been due to faulty technique.

FIG. 13



The two patients who went into labour following catheterisation were both in the last month of pregnancy, at which stage of pregnancy I have found that distension of the renal pelvis sufficient to cause colic is associated with the onset of uterine contractions. Similarly, in acute pyelitis, renal colic may be so severe as to initiate uterine contractions and cause a miscarriage even as early as the sixth month. If the renal colic in such a case is relieved by the passage of a ureteral catheter, the uterine contractions subside.

Termination of the pregnancy, either induced or spontaneous, is followed by a rapid improvement. As the passage of a catheter to a point above the pelvic brim has the same effect, the cause of the improvement in both instances is probably the relief of the compression of the ureter at the pelvic brim. The beneficial effect of the catheter remains after its withdrawal as the relief of tension probably enables the ureter to regain its tone and the increased intake of fluid made possible by the improved general condition of the patient stimulates ureteral peristalsis.

Summary

(1) Pregnant women show varying degrees of atony of the upper urinary tract. In some this is very slight so that no appreciable stasis is produced. In others it is very marked and can be shown to occur at the very beginning of pregnancy. (2) In the second half of pregnancy, dilatation and stasis frequently result and are due to pressure of the uterus on the atonic ureters at the pelvic brim. (3) Dilatation and stasis from the pelvic brim upwards can be produced in the non-pregnant by ovarian cysts.

of the marked elongation and kinking of the uret which is characteristic of pregnancy, even although the pressure exerted by the cyst may be greater than could possibly be exerted by the pregnant uterus. The atony peculiar to pregnancy is therefore the primary factor. (4) In normal pregnancy the tone of the ureters has been shown to improve nea term, and in cases of albuminuric toxæmia there is minimum of atony and stasis. In both instance there is believed to be an excess of posterior pituitar hormone in the blood. The primary factor in th production of the changes in the upper urinary trac in pregnancy is probably, therefore, a disturbance the endocrines. (5) Infection of the urinary tract common during pregnancy and is often unrecognised (6) Infection is always preceded by stasis and seldo clears up completely until the stasis is relieved termination of the pregnancy. (7) Early diagnosis most important, as if instituted early, simple trea ment by abundant fluids and alkalis is sufficient enable the patient to go to term. (8) Ureter catheterisation has a definite place in the treatment serious cases for the relief of pain and the promoti of drainage.

THE HIGH CARBOHYDRATE DIET IN TH TREATMENT OF DIABETES MELLITUS

BY GEORGE GRAHAM, M.D. CAMB., F.R.C.P. LON
PHYSICIAN TO OUT-PATIENTS, ST. BARTHOLOMEW'S HOSPIT

A. CLARK, M.D., M.R.C.P. LOND.
CHIEF ASSISTANT TO A MEDICAL UNIT OF THE HOSPITAL

AND

H. E. W. ROBERTON, M.B. CAMB.
LATE HOUSE PHYSICIAN TO THE HOSPITAL

AN important change has taken place in the l few years in the dietetic treatment of diabetes mellit Before the discovery of insulin the diet for a seve case was an extremely restricted one. The carb hydrate ration was very small (30–50 g.); the prote ration was about the same as at present (70 g the fat ration was often very large (150–200 g.). Ev larger amounts of fat (200–250 g.), with small amou of protein (20–50 g.) and of carbohydrate (30–40 g were advocated by Petren,[1] and Newburgh a Marsh.[2] The diet used by one of us (G. G.)[3] w approximately C. 42 g., P. 65 g., F. 123 g., Cals. 15

In 1923, when insulin was still very expensive 25s. for 100 units—the diet was at first little alter The insulin improved the health of the patients such an extent that there was a tendency to mainta the diet at the same level, even after the cost insulin had been much reduced. Some workers beg to increase the carbohydrate slightly, and in 19 Sansum, Blatherwick, and Bowden,[5] and in 19 Geyelin and Mackie,[4] published papers showing th much better results could be obtained if the carb hydrate was very considerably increased and t fat decreased. In 1930 Rabinowitch[6] [7] advocat has been responsible for arranging for the patients to attend the follow-up department of the hospital.

SYMPATHETIC CONTROL OF TISSUE CHANGE

AND ITS SURGICAL SIGNIFICANCE

BY R. CUNLIFFE SHAW, F.R.C.S. ENG.

HON. ASSISTANT SURGEON, PRESTON AND COUNTY OF LANCASTER ROYAL INFIRMARY

IT has been proved in many clinics that the ablation of the sympathetic nerve-supply to tissues that show pathological change results in a restoration of cell balance. It is my object to give the salient facts, derived from experimental inquiry, which help towards the elucidation of the nature of the relationship between the sympathetic nerve apparatus and the tissue cell, and to indicate the manner in which surgery acts in the restitution of the tissue change.

It is conceivable that those conditions for which surgery offers a beneficial line of treatment are due to one or other or both of the following disturbances :—

(*a*) Over-stimulation of the vasoconstrictor fibres might produce prolonged vascular spasm, causing impoverishment of the nutrient supply to the tissue cells, which undergo degenerative changes.

(*b*) Stimulation of the sympathetic fibres might directly produce abnormal metabolic changes resulting in pathological sequence.

In 1924 I showed[1] that stimulation of certain mixed nerves results in the variation of the threshold values for pressure pain ; later it was found that these changes were independent of the associated vascular response, and moreover they were prolonged by arresting the circulation, showing that the alteration of sensory perception was due to the accumulation of metabolites in the tissues, the direct result of physiochemical change produced by the nerve stimulus. Then followed the discovery of a comparable alteration in the pressure pain threshold after peri-arterial sympathectomy and ganglionectomy. Moreover, it was found that stimulation of the peri-arterial plexus during novocain block of the surrounding tissues resulted in a similar sensory phase.

The observation of Auguste Tournay[2] on the lowering of the threshold of sensory perception in the hind limb of dogs by sympathectomy, was demonstrated by the return of the nociceptive reflexes after their disappearance following division of the sciatic nerves. These results suggested confirmatory evidence, and, furthermore, it is to be recalled that Claude Bernard noted augmented sensitivity in animals after ganglionectomy. The work of Orbeli[3] has shown that sympathetic stimulation causes an increased muscle tissue and delays the onset of fatigue phenomena. He epitomised his conclusions in the statement that the sympathetic system exerts a profound influence over the physio-chemical changes of skeletal muscle and its functional ability. Maibach,[4] in 1928, confirmed the foregoing observations, and found that sympathetic stimulation delayed muscle fatigue in bloodless preparations, eliminating the possibility of the results being due to vasomotor response.

FIRST CONCLUSIONS

The results of the foregoing work may be conveniently stated as follows. Firstly, stimulation of the sympathetic system results in—

(1) Exaltation or depression of the sensory thresholds (for pressure pain in particular).

(*a*) This variable threshold potential is associated with vasomotor change, and it has been found that the diphasic mechanism might play an important part in the adjustment of the animal organism to external stimuli.

(*b*) The threshold changes were shown to be associated with the accumulation of metabolites in the tissue spaces, which prolong the new threshold phase.

(*c*) The threshold changes were shown to be independent of the vascular response.

(2) Increase of the motor response of muscle tissue during the onset of the fatigue phase. The sympathetic exerts a profound influence on the physiochemical changes in muscle tissue, modifying its functional ability ; this change is associated with—

(*a*) Increased consumption of oxygen by the muscle tissue.

(*b*) It is independent of vasomotor control.

In the second place it was shown that ablation of the sympathetic supply results in—

(1) The assumption of the minimum sensory threshold phase and the associated vasodilatation. In this state further electrical stimulation does not appear to produce any change in the new threshold value.

(2) Tournay has demonstrated that sympathectomy exalts the residual somatic sensation in a limb that has been deprived of its principle somatic innervations by division of the sciatic nerve. This hypersensitivity is shown by the return of the nociceptive reflexes.

FURTHER OBSERVATIONS

The next stage in the inquiry was a study of the effects of the irritation or ablation of the sympathetic pathway to a selected area of distribution ; for this purpose a series of experiments were carried out in which the sympathetic nerve-supply to the thyroid gland was either severed above the ganglion stellatum or subjected to chronic fibrotic irritation by surrounding the cervical sympathetic chain with slowly cicatrising autogenous muscle grafts. As a result of this work it was found that lesions developed in the thyroid gland and the superior cervical ganglion, those in the gland were initially of the nature of a cell hyperplasia followed secondarily by cell degeneration. In the ganglia there was a proliferation of the connective tissue and degeneration of the ganglion cells. It was observed that although these changes occurred both after nerve section and nerve irritation, they were more advanced in the irritative experiments, where masses of rapidly proliferating thyroid parenchyma entirely obliterated the normal acinic structure. A somewhat similar pathological change was observed to follow electrical stimulation of the cervical sympathetic in goats, as shown by the work of Wilson.[5] The conclusion was that removal of a normal sympathetic central control of the superior cervical ganglion resulted in nerve-cell changes in that ganglion, which in turn removed the restraint on cell growth and permitted hyperplasia, and, furthermore, that in those cases where an irritant element was to be adequate if the blood-sugar is below 130 mg. per cent. at this time of the day. No case has been included which did not fulfil these conditions. If the C/I ratio is below 2, the diabetic condition is very severe; 10 of our cases had a ratio between 1·2 and 1·8, and 11 between 2·2 and 3·9.

DISCUSSION

The explanation of the improvement in the diabetic condition is not easy. Rabinowitch suggested in 1930 that the improvement was due to the decrease in the caloric value of the diet, as a result of the decrease in the fat; but as the outcome of further experiences in 1931 he found that the same improvement might take place, although the caloric value of the diet was kept constant. Adlersberg, who uses different diets, according to the severity of the disease, was also inclined to ascribe the improvement to the lower caloric value. Our experience shows that the improvement cannot be due to a decrease in the caloric value, because it was slightly increased by the substitution of 60 to 80 g. of carbohydrate for 25 g. of fat. It seems more probable that the improvement is due to the alteration in the balance of the carbohydrate and fat. With a low carbohydrate diet, although the breath of the patients did not smell of acetone, the urine usually gave a definite reaction for aceto-acetic acid with Rothera's reagent; under the new régime it never gives any reaction.

This observation suggests that the presence of aceto-acetic acid or beta-oxybutyric acid in the blood may cause the increased demand for insulin, just as, for instance, the presence of a staphylococcal infection causes a great increase in the insulin demands. It is possible that some other intermediate product of metabolism, besides the acetone bodies, may be responsible for the change. This hypothesis is supported by the observations of Bainbridge,[13] on the diets given to the rats and mice used for testing the strength of insulin. She found that a diet containing much fat but no carbohydrate rendered the animals less sensitive to insulin than they were when having a mixed diet. She also thought that a diet of the same caloric value, containing no fat but much carbohydrate, rendered animals slightly more sensitive to insulin.

The fact that an improvement occurs, even though the fat ration is 100 g., is of great importance to the patients who have had diabetes for many years. They have got accustomed to a high fat ration, and when the bacon is reduced to 1 oz. a day, and the butter to 1 oz., they usually feel the privation. To reduce the fat to 50 g. makes the diet almost as intolerable for many patients as is the old diet of 40 g. of carbohydrate. Partly for this reason, and partly because the patients are doing so well, we are loth to recommend, for regular use, a diet of less than 100 g. of fat, but it should be reduced below 100 g. if acetone bodies are present in the urine at any time of the day. Children should be given a lower fat diet, because they form acetone bodies much more easily than adults.

Another possible explanation for the decrease in the insulin dosage is the actual improvement in the beta cells of the islands of Langerhans. So far there is no evidence available on this point.

It is difficult to conduct these experiments, which have to be done without adequate controls, and the search for the most suitable diet must be continued for many years. Some of the 15 "pedigree" patients are still improving, and require less insulin than they did in January, 1932. If in January, 1933, the fat in the diet is reduced by 20 g., and the carbohydrate increased by 45 g., it may be difficult to say whether any subsequent improvement is due to this last alteration in the diet, or would have taken place independently. Another difficulty is the occurrence of secondary infections, which may increase the insulin requirements. These do not seem to have disturbed the 15 "pedigree" patients in the last two years, and their general condition is certainly much better than it used to be.

The task of supervising the change in the diets has been made possible by the assistance of the hospital dietitian, Miss Abrahams, and our thanks are due to Miss Ball, who

The first two clinical entities that fall into this category are radio-dermatitis and leucoplakic vulvitis; in both cases there is an early stage of vascular dilatation associated with a hyperplasia of fibrous and elastic tissue cells, concurrently there is a proliferation of certain layers of the epithelial cells. In the later stages there are retrogressive changes in the connective tissues resulting in the development of hyaline areas and excessive fibrosis, whilst the epidermal layers undergo desquamation. Lastly, there develops a condition of cell imbalance in which the epithelial cells develop on dysgenetic lines and ultimately may invade the connective tissues at focal points. In both these conditions, surgical intervention upon the sympathetic system has resulted in complete cure or considerable improvement. In a series of 27 cases where the peri-arterial operation had been performed for radio-dermatitis, there were 12 complete cures and 7 considerably improved; these results were obtained from various continental clinics, and, moreover, the peri-arterial operation only was performed. Again, Leriche[9] completely cured a case of leucoplakic vulvitis that had advanced as far as the kraurotic stage by hypogastric sympathectomy.

It was therefore evident that ablation of the sympathetic innervation in either of these conditions causes (*a*) a cessation of the abnormal proliferative activity of epithelial and connective tissue cells; (*b*) an absorption of the excess of abnormal tissue; (*c*) permits the regeneration of normal tissue elements.

It follows that the sympathetic nervous system must be intimately concerned in the production of the earlier stages of these lesions, and that removal of the dyscontrol before the onset of epithelial invasion will restore cell balance. A comparison between these conditions and the sequence of pathological changes that precede the development of coal-tar cancer of the skin and carcinoma of the breast, as described by Sir Lenthal Cheatle, suggests that a similar mechanism is involved in the initial stages. In both these conditions there is early hyperplasia of elastic and fibrous tissues, together with an epithelial proliferation. In this association some very suggestive work has been accomplished by Rémond, Bernardberg, and Sendrail[10]; they found that the production of tar cancer in rabbits was more rapid in its development and precocious in its onset in an area of skin that had been deprived of its sympathetic supply. These results are also comparable to those obtained by Dobrzaniecki[11] and Magliulo,[12] who found that grafts of all types are more successful when applied over areas that have been deprived of their sympathetic innervation. Moreover, the first-named observed that wounds healed more readily after sympathectomy, and he concluded that the regeneration of epithelium, connective tissue, bone, and muscle, is accelerated by extirpation of the sympathetic control.

These facts harmonise with the view that the normal function of the sympathetic system is to act as a brake over cell growth, and that removal of the normal influence or its replacement by irritation produces physio-chemical changes that determine irregular cell hyperplasia.[11] Willy Meyer[13] has suggested that in cases of malignant disease there is a parasympathetic hypertonus which is associated with a definite alkalosis and the predominance of potassium ions. It is known that section of the splanchnic nerves causes a fall in the blood calcium, and therefore a deficiency of calcium ions or an excess of potassium ions would mean a deficiency of the sympathetic nervous influence; in other words, it would imply a loss of normal sympathetic control of the tissue cells. In this connexion it is interesting to observe that Fontaine and Jung,[14] studying the effects of wound healing after the removal of the superior cervical ganglion, have found that healing was more rapid on the sympathectomised side, and that the hydrogen-ion concentration of the exudate was found to vary very slightly from the alkaline to the acid side on the operated side, but that on the unoperated side the reaction was always distinctly acid.

CONCLUSIONS

1. That the sympathetic nerve control of the tissue cells is normally of the nature of a brake, preventing irregular and uneconomic proliferation. In this respect its activity may be compared to its inhibitory influence upon the sensory threshold, and the production of the brake phenomenon in muscle tissue.
2. That certain non-specific irritants act on the autonomic nerve mechanism, associated with the dermis and epidermis, and produce a definite sequence of pathological change characterised primarily by hyperplasia of fibrous elastic and epithelial tissue cells.
3. It is suggested that the derangement of the sympathetic-hormonic apparatus determines the initial development of neoplasms.
4. The surgical removal of the sympathetic nerve-supply acts essentially through extirpation of those factors that disturb the physio-chemical balance of the tissue cells, and that the passive effects of vasodilatation are of a secondary importance.

ACTUATION OF THE INERT DIAPHRAGM

BY A GRAVITY METHOD

BY FRANK C. EVE, M.D. CAMB., F.R.C.P. LOND.
CONSULTING PHYSICIAN, ROYAL INFIRMARY, HULL

FORMERLY I regarded the breathing thorax as a *concertina-bellows*; my present work suggests that it resembles rather a cylinder and piston. In older men the cylinder wall is often rigid and is scarcely used in respiration at rest. Hence in artificial respiration it seems much better to exploit the piston action of the diaphragm rather than to try to compress the rigid walls of the cylinder—leaving the piston flapping passively up or down and thus frustrating much of one's efforts to squeeze air in and out of the trachea.

The efficacy of the following method—simple but apparently novel—is illustrated by my first two cases: (1) post-diphtheritic paralysis of the diaphragm (successful); (2) Landry's paralysis, dying of failure of the heart, not of respiration.

Essentially the method consists of laying the patient on a stretcher, which is pivoted about its superadded there was a more profound degree of cell hyperplasia.

In another series of experiments[6] the sympathetic supply to an area of the arch of the aorta was subjected to chronic irritation and division, and at graded intervals after operation the animals were examined for evidence of pathological change. Allowing for intercurrent arterio-sclerosis, and taking into consideration the control animals, it was proved that a series of pathological changes occurred in the aorta of those animals that were irritated, whereas no results followed simple division of the sympathetic fibres at a distance from their distribution. In those cases where there were positive results the earliest change consisted in the proliferation of the connective tissue cells in the *intima, followed by a hyperplasia of the elastic tissue.* Here again it is to be strongly emphasised that the first result of sympathetic irritation on the tissue cells is one of increased and irregular growth, and similar to the previous experiments the proliferated tissue underwent a progressive sequence of degenerative changes, followed in the most advanced cases by calcification and the formation of atheromatous abscesses.

From the foregoing group of experiments it was concluded that irritation of the sympathetic supply produced a condition of cell imbalance allowing irregular hyperplasia, and therefore it suggested that the normal control was one of restraint towards cell growth. It is interesting to compare this conception of sympathetic function with the similar type of control which it has been shown is exercised over the sensory threshold, and, furthermore, it will be remembered that the brake phenomenon of Reiger in muscle tissue has been shown to be *dependent on the* sympathetic innervation.

The next question that arose involved the nature of the elemental disturbances which produced the tissue cell change observed in the foregoing experiments. As the result of a study of the conditions, the following factors give a definite balance in favour of the cell changes being due to direct interference with the metabolism of the tissue cells, relegating the part played by vasospasticity to a secondary position. These considerations are as follows:—

(1) *It was found that division of the cervical sympathetic* above the stellate ganglion caused cell hyperplasia in the superior pole of the thyroid gland; since the entire vaso-*constrictor pathway to this portion of the gland* had been severed, it follows that the hyperplastic changes in the thyroid must have been independent of vasopressor reactions.

(2) From a study of the effects of peri-arterial sympathectomy upon dermo-epidermal lesions, it has been proved in many surgical clinics that no inconsiderable percentage of cases are definitely improved or cured as the result of this procedure. It therefore follows that if we are to presume that the success of the operation is dependent upon the removal of a vasoconstrictor element, or conversely, that the ulcers persist on account of vascular spasm, one is faced with the difficulty of an uninterrupted vasoconstrictor supply through the principal mixed nerves of the limb, and it is incredible that the mere proximal interruption of the peri-arterial plexus could nullify the constrictor element if this were the *predominative factor.* In my experience the thermal effects of a peri-arterial operation are quite insignificant, and yet, despite this poor response, I have found *in my own small series of* cases there has been a definite progress from the date of operation up to a complete cure. It is interesting to note that Lewis has suggested *that* in some cases such operations as peri-arterial sympathectomy may produce beneficial results by the effects of trauma, bandaging, &c. In a case of bilateral ulceration on the legs I studied in detail the effect of the periarterial operation, and found that no change whatever occurred in the ulcers before sympathectomy, despite bandaging, dressings, &c., and yet these ulcers progressively healed, although the thermal response was also negligible after the first week.

(3) Polettini and Josué[7] produced intravascular tissue *hyperplasia by the fractional* dosage of animals with adrenaline over long periods. In a similar series of experiments I found that only one out of four animals *developed lesions. This observation* serves as a corollary to the experiments where irritation was found to produce aortic change. If adrenaline produced its action through the *induction of* vasomotor spasm, pathological change might be expected in all these cases.

(4) It will be recalled that the changes in the pressure *pain threshold* were produced during the stoppage of the circulation, and that the recovery period was considerably protracted owing to the accumulation of metabolites in the *tissue spaces. This suggests a comparison* with the cutaneous phenomena ascribed by Lewis to the antidromic reflexes through the sensory nerves and their vascular colateral. *He concluded that such impulses influenced* metabolism in the cells of the skin, releasing in the tissue spaces a vasodilator substance, especially in the epidermis, which is *plentifully and intimately supplied by nerve-*fibres belonging to the sensory nervous system. It might be added that the skin is equally well supplied with fibres [illegible] c system. In this association [illegible] Lewis has drawn a comparison [illegible] nknown vasodilator substance in the skin; and, further, the *proliferative* reactions following the injection of histamine into the muscle coat of the stomach of cats, as studied by O'Shaughnessy,[8] advances this hypothesis. The close chemical affinity between histamine and *adrenaline will be recalled in this association; these facts* suggest that certain of the hyperplastic reactions may result from stimulation of the tissue cells and the liberation of histamine or an allied substance, exciting hyperplastic conditions.

(5) It is to be noted that the researches of Y. Manouélian (1913) revealed that in many cases where arterio-sclerotic changes had advanced to a profound degree there were still perfectly normal vasa vasorum containing normal blood corpuscles in the wall of the diseased vessel. It would seem reasonable to suppose that if the changes in the main vessel were due to vascular spasm, then the minute nutrient vessels would be first affected, and become obliterated long before the gross changes in the intima of the main vessel. The contrary being the case suggests that the lesions were *due to alteration* of the cell metabolism through abnormal impulses descending to the terminals of the vascular innervation.

(6) The researches of Orbeli and his collaborators indicate that in muscle tissue there is a direct physio-chemical control through the autonomic apparatus.

The foregoing deductions show that in these conditions of tissue change, produced experimentally, the essential element that is disturbed is the control of the physio-chemical changes in the actual tissue cell, *irrespective of the vasomotor responses.* A study of certain clinical conditions was carried out with a view to obtaining similar evidence, and these observations may be briefly stated to present a complete sequence of evidence.

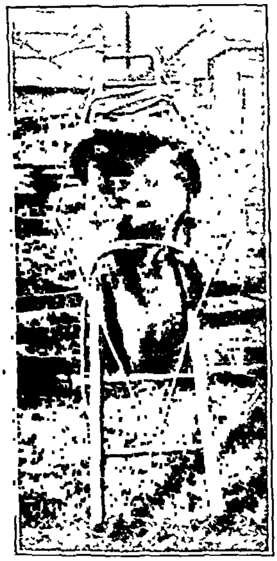
CELL GROWTH AND TISSUE CHANGE

The subject appeared to be intimately associated with the factors controlling cell growth, and suggested as a basis that the stimulus for tissue hyperplasia and its normal inhibition might in some way be partially associated with the autonomic system. The important metabolic changes that are normally affected through the influence of sympathetic nerve stimuli are well recognised, and the intimate coöperation between the autonomic system and the hormonic *secretions* indicate a mechanism for the direct control of physio-chemical change in the tissues, and it is conceivable that this apparatus once disorganised might lead to the most profound cell imbalance. There are certain clinical conditions associated with the *integument* which show a progressive sequence of tissue change, and, if left to develop, culminate in the gross hyperplasia of a dysgenetic type of epithelial cell that may invade the connective tissues and produce metastases. These conditions are further characterised by uniform type of primary pathological process, suggesting a definite tissue response to a non-specific stimulus through the same mechanism.

work for one man, who need not be skilled. This is very different to the skill and exhaustion demanded by the ordinary methods.

Dr. Cooper reported that after 8 P.M. his cyanosis and respiratory difficulty increased. Oxygen alone gave no relief. Although the rocking perhaps accentuated his distress, yet he had to have it every alternate ten minutes, because it promptly relieved the cyanosis, which returned when the apparatus was stopped. In short, "the apparatus did what it was asked to do." On August 9th at 10 A.M. Dr. Muir and I saw him together. He had then been seven hours in coma and his ribs and sternomastoids were paralysed. But a most encouraging feature was that the diaphragm was contracting regularly, though rather spasmodically, at 24 to the minute. However, at 12.30 the heart, which had so far been beating with unnatural strength, rapidly failed and he died at 12.45. This was very disappointing because the stage of respiratory failure (often brief) had apparently been tided over; and if the bulbar cardiac centres had not failed, complete recovery in three months was quite possible.

FIG. 3



Extemporised apparatus for prolonged artificial respiration, consisting of a 6-foot ladder on a low fence. The diamond lashing of the cord prevents the ladder sliding or getting oblique on the fence. Coats or blankets, hot bottles, and a rope to strap the buttocks should be added. Schafer's method is used till the apparatus is rigged up.

ADDENDA

(1) *Four skiagrams* (by Dr. Bannen).—These can be described verbally to save illustrations. The first pair shows the baby (Case 1) in the rocking-chair in the head-up and the head-down positions. The diaphragm is seen to have moved from the ninth to the tenth rib—a considerable change of air content. The other pair shows that my diaphragm was displaced 5 cm. when I was rocked on the apparatus through 50° each way. Voluntary respiratory movement was negligible. My chest measurement is 84 cm. Treating it as a cylinder and piston this excursion indicates roughly 1800 c.cm. of air. The shadow of the heart and large vessels is greatly changed in shape but not in area.

(2) *Measurement of air expired* on the rocking stretcher. This amounted to 1500 c.cm. in my son, aged 18 (chest 29 in., height 69 in.), without voluntary respiration. Schafer's method produced only 1000 c.cm. both in him and myself (chest 33 in., height 60 in.). In my son, seven up and down rockings per minute were ample for comfort without voluntary respiration. This would give more than the 6000 c.cm. of air which are said to be needed per minute. Ordinary tidal air is given as 500 c.cm. The method of measurement I used seemed reliable though rough.

If the method is to be tried for respiratory failure in spinal anæsthesia by the heavier fluids, I suggest that the rockings need be only five or six per minute, of which eight to ten seconds should be in the feet-down position and only two seconds in the head-down posture. Thus gravity should help to keep the heavy fluid away from the medulla. Presumably Schafer's method would be tried first, and the rocking apparatus only if prolonged resuscitation proved necessary.

COMMENT

These two cases, and my experiments on the healthy person, show that this gravity method of actuating the inert diaphragm is effective. If used with the patient face downwards, it offers, in my opinion, many important advantages (which I need not detail here) over the ordinary methods in use for resuscitation after drowning or gassing or anæsthetics and the like. Apparatus can be extemporised, as shown for instance in Fig. 3. I hope later to publish a much fuller paper with cases. As these are hard to come by, I should be glad of collaborators. With the experienced help of Mr. W. Riley, of the Wakefield Mines Rescue Station, and of Messrs. Siebe, Gorman and Co., of London, I am engaged in perfecting the apparatus and the method. I conclude that the method is novel because it was not mentioned in the full discussion at the British Association last year.

My thanks are due to Dr. Muir and Dr. Jacobs for their cases; to Dr. Bannen for the skiagrams; and to Ivor S. Eve for much willing help.

FATAL POLIOMYELITIS IN ADULTS

WITH CASE REPORTS

By Hugh G. Garland, M.D. Leeds, M.R.C.P. Lond.
MEDICAL TUTOR AND REGISTRAR, LEEDS GENERAL INFIRMARY
AND
F. F. Hellier, M.A. Camb., M.D., M.R.C.P. Lond.
RESIDENT MEDICAL OFFICER AT THE INFIRMARY

The death of three patients from acute respiratory failure of bulbar origin within a period of five days is a dramatic event even in a large general hospital. The three cases here recorded, although showing similar terminal symptoms, presented differences in other respects which gave rise to considerable difficulty in diagnosis during life.

THE FIRST CASE

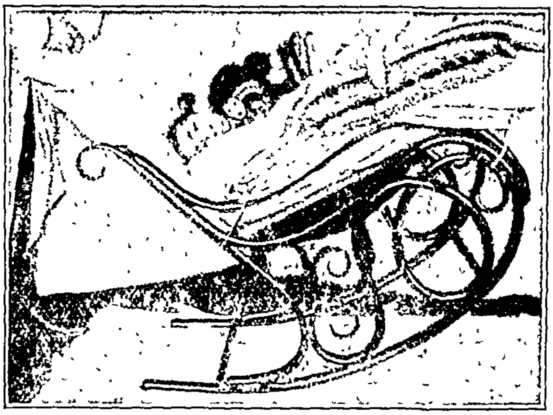
A nurse, aged 21, had suffered from a slight sore-throat for a week before the onset of the acute illness, for which she had not consulted a doctor, and during the last two or three days she had felt "off colour" and was constipated; she had also complained of insomnia. On the evening of August 30th she complained of slight pain in the neck and aching in the legs, but the temperature was normal; she did not however go on duty. The following morning she had a slight rise of temperature and had pain in the back; she was seen by one of us at 8 P.M. (August 31st) when she complained of pain in the neck, back, and legs. Her condition was in no way alarming, but she was rather restless and had difficulty in moving about the bed owing to the pain; the temperature was 100° F.

On examination there was tenderness on pressure over the neck, where there were some palpable lymph nodes, and there was slight neck rigidity. Kernig's sign was not present, though extreme flexion of the extended leg on the trunk was a little painful. The pupil reactions, *fundi, and tendon*-jerks were normal, and the plantar responses flexor. The abdominal reflexes however were absent and there was some disinclination to move her legs, although there was no definite loss of power; there were no sensory changes. No abnormality was discovered in the heart, lungs, or throat.

Course of illness.—She spent a very restless night despite a soporific, and about 5 A.M. she became much worse; at 5.30 she was desperately ill, with shallow breathing and cyanosis and complete absence of diaphragmatic movement. She had very little power in the legs but could move her toes; the pupils reacted sluggishly and the voice was feeble, but the tendon-jerks were still normal; consciousness was fully retained; the pulse-rate was now 98, respiration-rate 32, and temperature 97° F. Lumbar puncture was performed at once and the cerebro-spinal fluid pressure was found to be over 300 mm. At 7 A.M. she was unable to speak though she could recognise people;

middle on a trestle, and rocking up and down rhythmically so that the weight of the viscera pushes the flaccid diaphragm alternately up and down. *Anyone can convince himself that this method of* artificial respiration is adequate by lying on the apparatus in action. He will find that he need not breathe; it is done for him. Oxygen is not required—only air.

FIG. 1



CASE 1.—The child (dressed and convalescent) in the head-down position on the rocking-chair used when the diaphragm was paralysed. The retaining strap for the buttocks is missing.

TWO ILLUSTRATIVE CASES

CASE 1.—*Post-diphtheritic diaphragmatic paralysis* in a healthy child aged 2. Faucial diphtheria had developed five weeks earlier and had been treated with 8000 units of serum by Dr. Maurice Jacobs. A month after the onset he had noted nasal speech, nasal regurgitation, and some weakness *in the legs and neck. But the general* health was good and the child had been out in her pram for a few days. Then suddenly on Jan. 22nd, five weeks from the onset, the child became alarmingly ill. The nearest doctors were hastily summoned and they expected death in a few hours. I was asked to see the child by Dr. Jacobs who was then ill. I found her lying on her back, pale, and apparently drowning in her own gurgling bronchial secretions. The observation that the epigastrium did not rise in inspiration was sufficient, with the history, to give the above diagnosis.

The child was immediately put on her side, on pillows so arranged that the trachea was sloping decidedly downhill. The breathing rapidly became easier and quieter. In a few minutes a quantity of tenacious, frothy mucus could be removed from the mouth, the cheeks became pink, but there was the danger of pneumonia developing. The temperature then was 98° F. and never rose above 100°. Feeding was by egg-spoons of fluid, tipped into the lower cheek. *The same lateral tilted position was retained for* ten hours. It then occurred to me that, though the position was excellent for drainage, the weight of the abdominal contents would push up the diaphragm and cause some collapse of the lungs which would increase the risk of pneumonia. Further, that if a slow seesaw movement were provided the diaphragm would be pushed up and down by the viscera in imitation of its natural movements. Accordingly a rocking-chair was produced and a level bed made on it with several blankets. A towel pinned from arm to arm of the chair prevented *the child slipping* when the chair was tilted through 30° on each side of the horizontal. This was done by the parents about ten times a minute continuously for two days, except at meal times when the head-down position was maintained by a block (Fig. 1). The child appreciated the rocking, which conduced to sleep. No râles were heard, except after feeding owing to some pharyngeal paresis. Next day she was demanding biscuits in a nasal voice.

On the third day spontaneous movements of the diaphragm were to be seen in the epigastrium. It was unfortunate that radiography—by Dr. J. E. Bannen with a portable apparatus—had to be deferred to this day, but it shows the desired excursion of the diaphragm in the head-up and head-down positions.

Over-extension of the paralysed left sternomastoid was prevented by a strip of strapping approximating the mastoid to the sternum. The nurse was instructed to adjust pillows so that this was always kept in wrinkles and never taut. Foot-drop was similarly prevented by elastic. On the sixth day the child was very well, but feeding was still carried out in the head-down position to avoid risk of deglutition pneumonia.

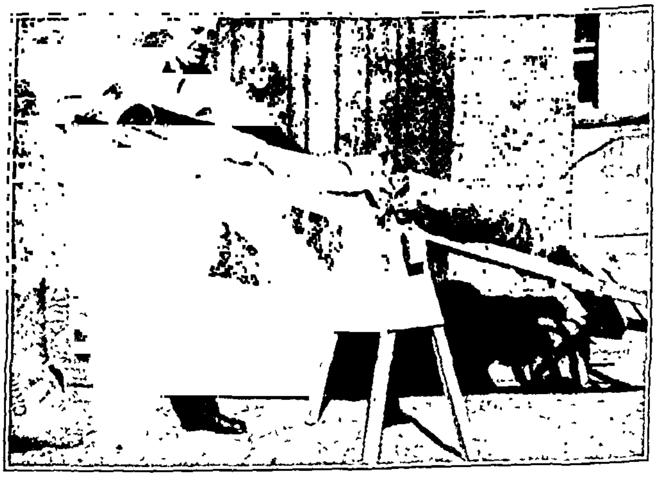
On the tenth day costal respiration ceased for four days. This caused no symptoms, which shows how unimportant *is costal respiration* compared with *diaphragmatic*; at rest it is redundant.

On the twenty-sixth day she could just stand unsupported. The neck muscles had recovered. Eventual recovery was complete.

CASE 2. *Landry's paralysis under artificial respiration.*—The patient was an athlete, aged 24, weighing 14 st. and 6 ft. tall. On August 2nd he was in his usual robust health and doing gymnastics. On the 3rd he was rapidly afflicted with paralysis of the legs and trunk, spreading later (partially) to the arms. After August 4th headache was severe. Respiratory difficulty started on the 6th. On the 7th he was admitted to the Sutton Annexe with marked retention of urine and *fæces. He was under* Dr. D. C. Muir, who very kindly allowed me to try this method of artificial respiration on him. I saw him on the 8th at 3 P.M. His legs were paralysed, arms weak, diaphragm not moving, but the upper ribs could be dragged up by the sternomastoids. Cyanosis slight, headache severe, swallowing normal, reflexes reported all absent. He was talkative; mentality a little abnormal and greatly distressed at his awful situation. Ordinary methods of artificial respiration could not have been tolerated in the state he was in. Accordingly at 6 P.M. a mattress was lashed to the special stretcher and the heavy patient lifted on to it easily by four persons. The stretcher was then lifted on to the trestle with his weight balanced over the pivots. A strong strap over his buttocks prevented his slipping (Fig. 2). Blankets covered him and he lay on his back.

Artificial respiration was started at 6 P.M. by rocking through 50° each way, regulated by a home-made mercury egg-boiler which allowed 4 secs. in the leg-down position and 3 secs. in the head-down. The latter promptly caused a *few ounces of clear* fluid to fall out of the stomach; perhaps the sphincters of the gullet were paralysed. There was some distension from flatus, but not enough to prevent visible excursion of the diaphragm. Evidently he felt relief from the rocking for, in spite of his distress, he demanded it for about five minutes every quarter of an hour.

FIG. 2



Rough apparatus used in Case 2; but here the subject is healthy and the position prone, as if for an unconscious patient.

After helping for three hours I left him in the able hands of our resident, Dr. J. D. Cooper, who spent most of the night with him, aided by two Toc H volunteers. Even with this cheap improvised apparatus artificial respiration was easy in diagnosis in each of them, the first on account of its fulminating course and scanty signs, the second because of the normal cerebro-spinal fluid, and the third on account of its resemblance to poliomyelitis in spite of its pathological distinction.

We wish to express our thanks to Dr. Veale for permission to use the clinical notes of these cases, and to Dr. Greenfield for his advice on the histological appearances.

Clinical and Laboratory Notes

THE TREATMENT OF LARYNGEAL TUBERCULOSIS

TWO PRACTICAL POINTS

BY SIR JAMES DUNDAS-GRANT, K.B.E., M.D. EDIN., F.R.C.S. ENG.

CONSULTING SURGEON TO THE CENTRAL LONDON THROAT AND EAR HOSPITAL AND TO THE BROMPTON HOSPITAL

IN dealing with tuberculosis of the larynx we have to afford relief from pain by every means in our power so as to counteract the steady downward progress which it initiates and maintains. The depressing effect, as much as the interference with nutrition, is from the psychological point of view deplorable. I and others have fully described methods which have found their way into current practice, such as the inhalation of such powders as anæsthesin and orthoform, the application of the galvano-cautery and alcohol injection into the superior laryngeal nerve. I have also pointed out elsewhere that a sudden attack of pain in swallowing, though sometimes due to an outburst of pharyngeal tuberculosis, is sometimes found to be the result of an ordinary acute tonsillitis passing off in a few days.

I wish, however, to indicate a cause of what patients call "pain," the relief from which is anxiously desired. In reality it is a painful "burning" stiffness of the pharynx caused by the drying and inspissation of mucus on the back wall, and is experienced chiefly on waking. Patients have frequently described the discomfort as severe pain and have been delighted to have it removed by gargling with a little bicarbonate of soda in water, warm if possible, otherwise cold. Such a solution can be put into a thermos-flask at night so as to be ready for use when the patient wakes up. I am sure that this condition is overlooked while deeper-lying sources of pain are being sought for. It seems a trifling method of treatment, but it gives great relief and is, of course, available to any practitioner if he only keeps the condition in mind and looks for it.

My second practical point is addressed to experts rather than to practitioners in general. In other places I have dwelt on pain as an indication and the strongest one for the galvano-cautery, and by no means as a contra-indication, as has been suggested. The typical tearing pain is almost invariably caused by a spot of ulceration, and if the exciting spot can be localised the application of a fine galvano-cautery point destroys the exposed nerve-endings and removes the pain. If there is a very small area of ulceration it may be difficult to find, and occasionally it lies concealed by an overhanging infiltrated epiglottis at the place where this joins the ary-epiglottic folds. If, on the other hand, the ulceration is very extensive, it may be only at some localisable spot that the pain is excited, and if the cautery is applied to other parts of the ulcerated area and not to the pain-exciting one, the relief is not forthcoming and disappointment ensues. The practical point that I wish to emphasise is that a laryngeal probe coated with cotton-wool should be applied to various parts of the larynx until the patient makes it known that the pain-producing spot has been touched. After cocainisation of the part the fine point of the galvano-cautery should be stuck into the spot, and in the absence of other sensitive spots pain is usually removed.

I see from time to time an ex-policeman who suffered from chronic pulmonary tuberculosis. When he was first referred to me swallowing was so painful that he was unable to take enough food to fight against the disease. I found a small ulcer on the middle of the margin of the epiglottis. I applied the galvano-cautery to the painful ulcer, and from that moment the excruciating pain disappeared; he was able to take food and make a good recovery, ultimately working hard on a chicken-farm.

Within the last few months I have been treating a man who suffered from fairly advanced tuberculosis. Temperamentally depressed, he was the picture of resentful misery and complained of intense pain in swallowing, especially on the right side. He used anæsthesin and orthoform powder, and had the superior laryngeal nerve injected on two occasions with only slight temporary benefit. I then tested the various parts of his larynx with the probe and found on the right ary-epiglottic fold an area of extreme tenderness. I punctured this spot with the galvano-cautery and hoped for the best, but in view of the patient's temperature I feared he would go rapidly downhill. A fortnight later when I asked to see him I expected to hear that he was confined to bed if, indeed, still alive. On the contrary, however, he had improved from the time of the localised galvano-cautery, took food, lost his depression, and was reported to have gone for an "outing." When next seen, he was fairly strong and quite cheerful. I am convinced that without the relief afforded by the localised galvano-cautery he would not have rallied.

My first "practical point" is addressed to the practitioner as simple and efficacious; the second is naturally more within the scope of the specialist, but with the increased attention to laryngology it may be applied by others. To all those who wish to practise such manipulations I cannot too strongly recommend the use of the left hand for holding the laryngeal mirror, in season and out of season, so as to leave the right one free for the handling of intralaryngeal instruments.

FŒTAL ASCITES

BY RICHARD H. HUNTER, M.D., M.CH., PH.D. BELF.

LECTURER IN ANATOMY, QUEEN'S UNIVERSITY, BELFAST

CASES of fœtal ascites, though rare, have been observed from time to time, and are of considerable interest to the obstetrician because of the difficulty in delivering the child's distended abdomen. The condition has been ascribed to many causes, among them (*a*) obstruction to the portal circulation, due to perihepatitis, syphilitic gumma, or tumours pressing on the portal vein; (*b*) chronic peritonitis due to syphilitis; (*c*) tumours or distended bladder pressing on the large vessels of the abdomen; (*d*) hypoplasia of the urinary organs; and (*e*) defects in the circulatory systems—e.g., absence of the ductus venosus or splenic vein. The present series of cases of fœtal ascites, though a short one, is of sufficient interest to warrant its publication because it includes examples of most of these causes.

CASE 1.—The abdomen of this specimen was enormously enlarged. There was no trace of an anal opening, and male external genital organs were present. The fluid which had caused the distension had been lost during the confinement, owing to the necessary surgical interference, and six pints of fluid were required to re-distend the abdomen to its original condition. An enormous "cyst" was found occupying the about this time she began to make plucking movements with her hands. She died at 8.40 A.M.

The C.S.F. contained 60 polymorph cells per c.mm.; chlorides 0·73 per cent.; no organisms seen; culture sterile. A partial post-mortem was carried out, the brain only being removed; it showed no naked-eye abnormality and was fixed intact.

Histology.—Medulla: There are two zones of acute perivascular softening and infiltration round vessels in the dorsal part of the medulla, probably in relation to the cells of the nucleus gracilis; there is perivascular infiltration with fairly large cells throughout the medulla, most marked in the dorsal part. Pons: There is infiltration by microglia and macrophages in relation to the sixth nucleus and substantia ferruginea; ventrally there are no definite zones of perivascular infiltration, but there is abundant infiltration in the dorsal region. Thalamus: There is slight perivascular infiltration of only a few vessels.

THE SECOND CASE

A female, aged 24, was admitted under the care of Dr. R. A. Veale on Sept. 1st. She had enjoyed good health all her life except for attacks of "influenza," which had occurred frequently during the past few years; these attacks consisted of coryza, slight cough, and pyrexia. Fourteen days before admission (August 18th) she developed an attack of the usual type which lasted about five days, but on the eleventh day (August 29th) she again felt poorly and developed aching pains and severe frontal headache; a diagnosis of "influenza" was again made. The following day, that is about 36 hours after the beginning of the recurrence, she felt some difficulty in getting out of bed and about the same time she noticed a feeling of weakness in the left hand. The next morning (August 30th) she found that the left side of the face was swollen, that she was unable to close her left eye, and that on swallowing fluid dribbled from the left corner of the mouth; the pain had disappeared and there was almost complete paralysis of the left arm. Forty-eight hours later she was admitted to hospital.

On admission she was complaining of diplopia on looking to the right, though there was no demonstrable ocular palsy; there was a complete left facial palsy of infranuclear type, otherwise the cranial nerves showed no abnormality. She was unable to raise her head from the pillow or to sit up. The left arm showed complete flaccid paralysis, and there was marked weakness and hypotonia of the right. The left leg was weak and hypotonic, the right being normal; the tendon-jerks in the arms were sluggish, the left knee-jerk was absent, the other jerks being normal; the left upper abdominal reflex was absent, the left plantar response extensor, and the right equivocal.

Course of illness.—The following day (Sept. 2nd) the right arm and the left leg were much weaker, the left lower and right upper abdominal reflexes had disappeared, both knee- and ankle-jerks were absent, and both plantar responses extensor. There was now some difficulty in coughing. On Sept. 3rd there was complete flaccid paralysis of the left leg with increasing weakness of the right; all the tendon-jerks were now absent, as were the abdominal reflexes; fine nystagmus was noted on looking to the left. During the next 24 hours there was increasing weakness of the right limbs; on the night of Sept. 4th–5th she developed respiratory distress, with numerous adventitious sounds in the chest, and cyanosis; death occurred at 11.50 A.M., consciousness being preserved up to the last.

The C.S.F. taken on Sept. 2nd showed four lymphocytes per c.mm.; protein 50 mg. per 100 c.cm.; chlorides 0·72 per cent. Blood Wassermann reaction negative.

Throughout the illness the fundus oculi was normal, there were no sensory phenomena, and no cerebral symptoms. There was neither sphincter disturbance nor insomnia. The temperature was subnormal throughout (97° to 98° F.), and the pulse-rate varied from 84 to 100, the respiratory rate being 24 with a terminal rise.

Post-mortem examination was carried out by Dr. J. G. Thomson at 3 P.M. on the day of death. There was severe mucopurulent bronchitis and intense congestion of the liver. The brain and spinal cord were fixed intact. Bacteriological investigations were carried out by Prof. J. W. McLeod, to whom we are indebted for the following details. Two rabbits were inoculated by corneal scarification with emulsion from the cortex and the medulla, and two other rabbits by intracerebral inoculation; all these animals remained normal. A monkey (*Macacus rhesus*) was inoculated by intracerebral injection; it was ill for three days and then returned more or less to its normal condition; about three weeks later it was noticed to be subdued and quiet and at present it lies in its cage and after walking a few steps will lie down exhausted; when walking it appears to have weakness of all its limbs though there is no paralysis.

Histology.—The spinal cord shows the typical changes of poliomyelitis with perivascular softening and infiltration with macrophages. Medulla: There is perivascular infiltration only. Liver: Apart from severe congestion there are no histological changes.

THE THIRD CASE

A boot repairer, aged 30, was admitted under the care of Dr. Veale on Sept. 2nd with a history of pains in the legs of one month duration; more recently there had been gradual loss of use of the legs.

The temperature was 99·2° F., pulse-rate 152, and respiration-rate 30. He was very pale, short of breath, and was vomiting everything; the liver was palpable and there was some clubbing of the fingers. There was a leucocytosis of 13,700 per c.mm. (polymorphs 91 per cent.), otherwise the blood showed nothing abnormal. The pupils were contracted and reacted very sluggishly to light; fundi normal. There was bilateral sixth nerve palsy, other ocular movements being normal. The legs showed complete flaccid paralysis with absence of the left knee- and ankle-jerks, those on the right being just obtainable; the plantar responses were equivocal. There was no sphincter disturbance. The cyanosis and respiratory distress increased and he died at 7.15 A.M. on Sept. 4th.

Post-mortem examination was carried out by Dr. Thomson. The lungs showed œdema and there were small bilateral pleural effusions. The stomach showed well-marked pyloric stenosis due to a healed ulcer. The brain and spinal cord were fixed intact and showed no naked-eye changes.

Histology.—There was no histological evidence of disease and Dr. J. G. Greenfield, who kindly examined the sections, thought the case to be probably one of Landry's paralysis.

COMMENTARY

The first of these cases is remarkable for its fulminating course, the patient dying within 36 hours of the onset of any definite symptoms and within 12 hours of the onset of physical signs; the first signs to appear were slight neck rigidity and loss of the abdominal reflexes, and there was marked tenderness on pressure over the shoulders and neck, in fact at this stage the possibility of fibrositis had been considered. The second case was a typical example of poliomyelitis of the spreading spinal type and it is of interest to note the left hemiplegic emphasis as well as signs of pyramidal involvement. The third case resembled the second in many respects and the two could not be differentiated clinically.

In all three cases consciousness was fully retained even though there was ultimate inability to speak. The cerebro-spinal fluid in the first case, the examination of which had not been completed when the patient died, was characteristic of an early stage of poliomyelitis, but the fluid in the second case was normal, although J. S. Collier[1] claims typical changes in 98 per cent. of cases.

The incidence of bulbar involvement in poliomyelitis is low (W. G. Scott Brown[2]), though the mortality in such cases is high, and it is interesting that these are the first two cases of poliomyelitis in adults that have been seen in this hospital for at least two years; nor have they coincided with any recent increase in the number of children admitted with the disease.

Unfortunately we had no opportunity of giving anti-poliomyelitis serum in these cases, though in this connexion W. D. Ayer[3] states that "bulbar cases are to be left severely alone" and in his opinion "lumbar puncture and intraspinal serum are sharply contra-indicated"; Collier, on the other hand, states that lumbar puncture can do no harm. It is possible that poliomyelitis serum might have saved the life of Case 2, though it would have been of no value in Case 3.

In conclusion, we are recording these cases in view of the epidemic of poliomyelitis at present existing in this country and would emphasise the difficulties contracted. The veins of the abdominal organs were engorged and the liver was congested. The œdematous condition of the organs extended to the heart, lungs, and brain. Microscopic section of the kidneys showed the early stages of congenital polycystic disease; the secreting tubules were greatly dilated and the glomeruli were congested. Unfortunately in this case, which was seen in private practice, the blood reactions were not tested. A history of previous miscarriages is, however, suggestive of syphilitic infection.

---

[1] THE LANCET, 1927, i., 321.

[2] Ibid., 1931, ii., 1287.

[3] Proc. Inter-State Postgrad. Med. Assembly (North America), 1928, p. 319.

Three of the cases described are cases of true fœtal ascites, two having generalised œdema. One of these is due to a congenital maldevelopment of the kidneys, and the other two to interference with the portal system. In two of the four cases there is a definite maternal history of syphilis; in one there is a suggestive history of miscarriages; and in one there is no direct evidence of syphilis. This proportion of syphilitic cases is not in agreement with that usually described. Fordyce[2] collected 63 cases of fœtal ascites and found that syphilis could be definitely proved only in eight. Birnbaum and Blacker,[3] on the other hand, state: "The most frequent cause of this condition is no doubt syphilis." It seems probable that the modern methods of diagnosis of syphilis will show Birnbaum and Blacker to be right.

RESUSCITATION OF INFANTS

WITH CARBON DIOXIDE AND OXYGEN

By J. B. Blaikley, M.B. Lond., F.R.C.S. Eng.

GYNÆCOLOGICAL AND OBSTETRIC REGISTRAR, GUY'S HOSPITAL

Of recent months, following the long-delayed appreciation of the work of Haldane, Pembrey, and others in this country, and the work of Yandell Henderson and others in America, attention has been focused on the use of carbon dioxide as a respiratory stimulant, so that several articles have appeared in current journals, dealing more especially with its post-operative application, but also pointing out its value in the resuscitation of the newly born infant. My excuse for the present paper is to put on record the success that has attended the use of carbon dioxide in the midwifery practice of Guy's Hospital during the past six months, and, further, to make one or two points that have been learnt as a result of our experience. Originally the "sparklet" pocket outfit was used, but this has been modified by the addition of a rubber bag of about 3–4 litres capacity, and a face-piece of transparent celluloid[4]; furthermore, a mixture of carbon dioxide, 5–7 per cent. and pure oxygen is always used, for reasons to be given later.

While it must be very seldom that a newly born infant actually dies from asphyxia, this does occasionally happen, and for every one there are numbers in whom respiration is only established after prolonged asphyxia. Though it is difficult of proof, it seems only too likely that the cells of the central nervous system are liable, in these latter cases, to suffer from the lengthy period of anoxæmia. This may be inferred by analogy with older children, in whom the results are more apparent; for example, I well remember a child who was anæsthetised with gas and oxygen, but was allowed to become markedly asphyxiated; this child for days afterwards was completely irrational to the point of insanity. Again, occasionally an infant difficult to resuscitate lives two or three days and then dies after increasing difficulty with respiration and feeding: post mortem, nothing except the subserous petechial hæmorrhages of asphyxia are found. Death is presumably in such cases delayed but none the less the result of asphyxia at birth. Lastly, it must still be borne in mind that many authorities consider the spastic infantile paralyses to be the result of prolonged asphyxia at birth. It therefore does appear to be the right and proper course to limit the time during which asphyxia is present to as short as possible, for there is no reason to conclude that the brain of a newly born infant is immune to the damaging results of anoxæmia.

The first need of the child is oxygen, and for this reason we have used a mixture of carbon dioxide and pure oxygen; in this way, it is ensured that the first few breaths achieve the maximum in oxygenating the anoxæmic blood. From experience we are convinced that more rapid recovery is thus effected than from giving carbon dioxide mixed with air. When given by the closed method used, 5–7 per cent. carbon dioxide is sufficient to stimulate respiration, higher percentages seem unnecessary and may even be toxic in action.

The closed method of administration with a bag and face-piece has several advantages. In hospital, large cylinders of gas are available, but in portable form it is necessary to conserve the supply of gas. The bag may be filled and then the infant allowed to breathe in and out of it, the percentage of carbon dioxide slowly rises, and that of the oxygen slowly falls; 3–4 litres will last ten minutes, more than long enough for full establishment of deep respiration. Of even greater advantage is the fact that it is possible to give artificial respiration, sucking the gas in and out of the bag, so that the full use is made of the volume of lung expanded, the oxygen absorbed relieving the anoxæmia, and the carbon dioxide stimulating the respiratory centre. In the absence of spontaneous respiration, artificial respiration by Sylvester's method will expand about half of the lung volume. It is necessary to have an assistant to hold the mask in place and the jaw forward; he is also able to steady the infant by holding the feet. We have used bent tongue forceps[5] in order to ensure that there is a clear airway.

In addition to the benefits outlined above, there is no doubt that much anxiety is saved the obstetrician in rapid establishment of respiration; also, as has often been pointed out, full expansion of the lungs is to be anticipated, and there is little fear of subsequent symptoms of atelectasis.

I would thank the obstetric surgeons of Guy's Hospital from whose cases the experiences recorded above have been obtained, in particular Mr. Cook, who originally excited my interest.

Coventry Hospitals.—The report of the Coventry and District Crippled Children's Guild for the year ending March 31st last shows that 1439 patients were treated, of whom 264 were discharged cured and 65 improved. There were over 10,000 attendances at the clinics. The report calls attention to the number of parents who refuse to have their children treated, and expresses a definite opinion that the law should compel parents, in case of need, to give their children the benefit of treatment.—Captain W. F. Strickland, M.P., recently formally opened the Alexander Private Hospital at Coventry. The institution has accommodation for 14 patients, and there is a theatre with other adjuncts.

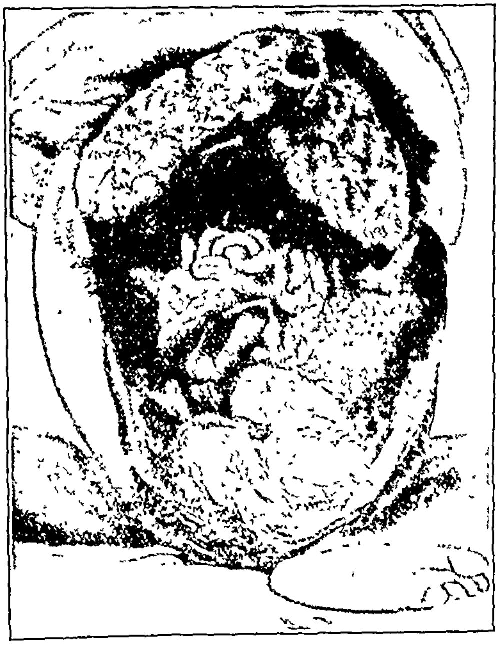
pelvic and right and left lumbar and subphrenic regions. A diverticulum of the "cyst" passed upwards, behind, and to the right of the coils of intestine, which were smaller than normal for a full-term infant. The lower end of the large gut was greatly dilated with meconium and was adherent to the upper and back portion of the left side of the "cyst"; the gut, however, had no opening into the "cyst," but ended blindly. The left kidney could not be distinguished, but in its position, below the suprarenal gland, there was some thickened tissue at the upper end of an enormously dilated left hydronephrosis, and this proved on microscopical examination to be the small amount of persisting kidney tissue. Both ureters were greatly dilated, and both passed through the wall of the "cyst." The interior of the "cyst" presented the appearance of a distended and greatly hypertrophied bladder, marked by numerous ridges due to the hypertrophy of the underlying muscle. The ureters opened into it by exceedingly small orifices which were by no means easy to find. The pelvic portion of the "cyst" was perfectly smooth; there was no trace of an opening from it. The testes were smaller than normal, and lay on the lower part of the dorsal surface of the "cyst." They were connected to it by short, well-developed, and unenlarged vasa deferentia which ran transversely medially, and opened into a shallow median diverticulum of the "cyst." There were no seminal vesicles. The maternal blood reactions were reported: Harrison + +, Fleming + +.

The "cyst" seems to have been an enormously distended urogenital sinus and ventral cloaca. The shallow diverticulum into which the vasa defferentia opened was smooth and had a thinner wall than the rest; this was the part of the urogenital sinus which should normally form the prostatic part of the urethra. This case, although described as one of "fœtal ascites," is really a case of arrested development of the hind-end of the fœtus after the urorectal septum had separated bladder from rectum, with imperforate anus and failure of fusion of the ectodermal part of the urethra with the entodermal part derived from the urogenital sinus. This defect of the urinary passage is one of the most uncommon forms of anomaly in the human fœtus, and in the literature at my disposal I have been able to find only one other similar case.[1]

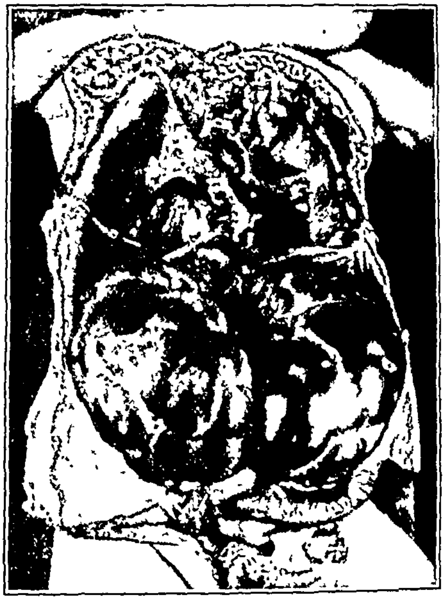
FIG. 1 (Case 2)



Dissection in Case 2, showing the nodular appearance of the atrophic liver.

CASE 2 was a full-term infant, delivered with the aid of forceps, and on external examination it appeared normal except for great distension of the abdomen. On opening the abdomen three pints of pale straw-coloured fluid escaped. The urinary organs were normal, but the liver was smaller than is usual in the newly born and had the rough nodular appearance typical of an atrophic multilobular cirrhosis (Fig. 1). Microscopical examination confirmed this diagnosis. The Levaditi technique for the demonstration of spirochætes was used on the liver, but they were not detected. The maternal blood count was reported: Harrison + +, Fleming + +.

FIG. 2 (Case 4)



Dissection in Case 4, showing the position of the large lobulated kidneys within the abdominal cavity.

The condition of this liver appeared to be due to fœtal syphilis or the chronic toxæmia of a maternal syphilitic infection.

CASE 3 was a fœtus of about the eighth month, born without assistance after a prolonged labour. It had the characteristic appearance of a generalised œdema. On opening the abdomen 160 c.cm. of deep amber-coloured fluid escaped, and from the left side of the opening an enormously enlarged spleen presented itself. This organ was found to measure 7 in. in length. The splenic artery was the normal size for a newly born infant, but the portal and splenic veins were small and had so narrow a lumen that a bristle could only be inserted with difficulty. This disparity between the splenic artery and vein seems to account for the engorged condition and enlargement of the spleen.

This was, therefore, a case of hypoplasia of the splenic and portal veins. The ascites was probably due to the hypoplasia of the portal rather than of the splenic vein, as it is known that experimental ligature of the splenic vein does not cause ascites, while ligature of the portal vein does. All the other organs of the body appeared to be normal, apart from the œdematous infiltration throughout the tissues. There was no evidence of syphilis in the fœtus, and the maternal blood was reported negative to both the Harrison and the Fleming reactions.

CASE 4.—This infant was apparently full-term and was delivered with forceps. It presented a generalised œdema and a distended abdomen. On opening the abdomen 200 c.cm. of amber-coloured fluid escaped, and two large lobulated, tumour-like kidneys were exposed (Fig. 2). The right kidney weighed 140 g. and the left 135 g. The ureters were extremely small, and it was not possible to pass even a fine bristle into their lumen. The bladder was small and number of cases the alleged accident could be shown to have no connexion with the death, but obscure causes were sometimes found for otherwise mysterious deaths.

[1] Cruickshank, J. N.: Brit. Med. Jour., 1921, ii., 980.

Dr. **Morgan Finucane** took exception to Sir John's advice to doctors examining such cases to harden their hearts, put off their bedside manner, and remember that the work was "business." The doctor's business, for whichever side he appeared, was to work for humanity and to deal with his cases from a human and sympathetic point of view. Functional nervous disease was in itself a reason why an injured man should continue to draw compensation, and the courts had held during the last few years that nervous troubles arising out of employment were ground for recompense.

Mr. **Sydney Vernon**, as a solicitor in general practice, gave the opinion that one of the finest cures for neurasthenia was a lump sum in settlement. He urged doctors to use simple language in their dealings with laymen.

Mr. **W. M. Walker** denied that the best place for the discussion on compensation was the medical consulting-room. The Bar had an invariable rule that counsel did not leave chambers for the purpose of consultation, and he felt that this was right. The case was to be tried not in a court of medicine but in a court of law, and the atmosphere of a barrister's chambers was a more desirable approach towards the courts. The Bar resented the tendency towards a medical tribunal which would be induced if barristers had to go to the medical consulting-room. The speaker pleaded for the simplification of the mass of certificates necessary under the National Health Insurance Act, which demanded that a doctor should be almost as good a draughtsman as a conveyancing solicitor. Some scheme should be evolved, he held, for deciding whether a man was a malingerer or not without the present multiplicity of consultations. Doctors should be less reluctant to give evidence against one of their own profession who had clearly made a mistake.

Dr. **R. A. Lyster** took exception to Mr. Walker's criticism of the procedure under the Act. The Institution of Medical Referees had deterred many persons at the outset from making claims, and these officers had frequently exposed unjustified demands on the fund. A doctor had no need to be a draughtsman, but only to give rather more care than before in coöperating with the approved society.

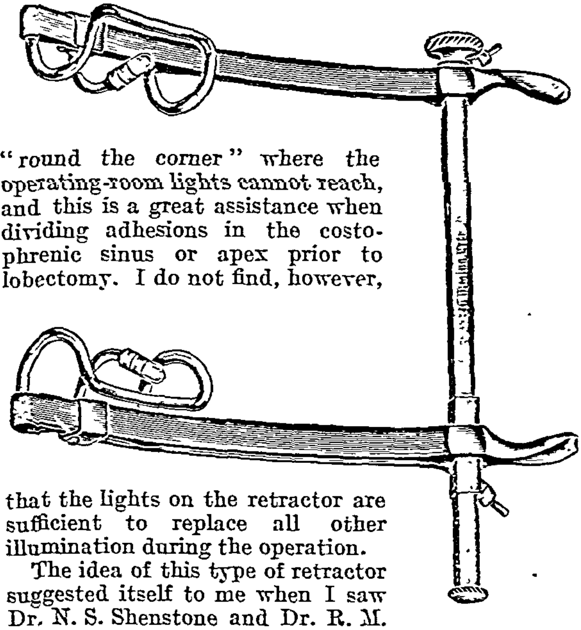
The **President** said that in his experience injured workmen were only too anxious to get back to work, and often made nuisances of themselves by hanging round the works before they were fit. He stressed especially the necessity for medical witnesses to learn how to behave in the witness-box. He reminded doctors of their great responsibility towards a claimant and his family in deciding whether or not the injured man should return to work.

Leeds Mental Defectives.—Dr. Arthur Hawkyard, chairman of the Leeds corporation mental health services committee, has recently opened extensions of the Meanwood Park Colony. There are seven new buildings, consisting of three villas for adult female defectives, each housing 60 patients; two villas for 50 boys and 50 girls respectively; a villa for 20 male and 20 female low-grade patients; and a school. The buildings have been placed round Meanwood Hall, which is the headquarters of the colony. The cost has somewhat exceeded £52,000, but it is expected that £5000 per annum will be saved by transferring patients from other institutions outside the city.

NEW INVENTIONS

A RIB-RETRACTOR FOR MAJOR THORACOTOMIES

This instrument is a modification of the ordinary abdominal retractor. The arms are longer and slightly curved so that they will lie against the chest wall; also the blades are 2¼ inches wide and curved to a semicircle. In addition it carries a 3-volt lamp on each side for illumination. The light carriers, which are curved to the shape of the blades, clip on to the arms and at their other ends are connexions for the electric leads. These leads are rubber-covered and sterilised by boiling. The lights will illuminate "round the corner" where the operating-room lights cannot reach, and this is a great assistance when dividing adhesions in the costo-phrenic sinus or apex prior to lobectomy. I do not find, however, that the lights on the retractor are sufficient to replace all other illumination during the operation.



The idea of this type of retractor suggested itself to me when I saw Dr. N. S. Shenstone and Dr. R. M. Janes at the Toronto General Hospital using a Balfour abdominal retractor for the ribs in thoracotomies for one-stage pulmonary lobectomies.

It is not intended that this instrument be used for forcing the ribs apart as Quervain's rib-spreader is used, but as a retractor to maintain the opening after the ribs have been spread. A description of a thoracotomy will best illustrate how the instrument is used:—

> The intercostal muscles and parietal pleura of the selected intercostal space are divided from the costal cartilage in front to the transverse process behind. The ribs above and below the incision are divided posteriorly at the tip of the transverse process. the fingers of the two hands are then inserted into the chest and the ribs steadily but forcibly pulled apart. The hands are then withdrawn and the rib-retractor is inserted and opened out. By this means one obtains in an adult a spread of 4–4½ inches between the ribs at their widest part.

I have used this thoracotomy for lobectomies; it also provides an excellent approach in operation for diaphragmatic hernia and exposure of the œsophagus or mediastinum in certain cases. This approach to the hemithorax causes surprisingly little shock, provides an enormous opening which can be easily and rapidly closed, and leaves no deformity of the chest wall.

I would like to thank Mr. Schranz, of the Genito-Urinary Manufacturing Co., for the trouble he took in making this instrument for me.

H. P. Nelson, M.B., F.R.C.S.

MEDICAL SOCIETIES

THE MEDICO-LEGAL SOCIETY

AT a meeting of this society on Oct. 27th the chair was taken by Lord RIDDELL, the President, and a paper on

Fraud in Medico-legal Practice

was read by Sir JOHN COLLIE. He advised the practitioner examining a medico-legal case to dispense with his bedside manner, for this was a business transaction. He must, however, retain his tact, for judgment, skill, foresight, and even experience were beads unstrung without infinite tact. The consulting-room was the best place for the examination; it was the doctor's own house, his own room, and he was master; the mental effect was enormous. The examiner should not be in too great a hurry to diagnose a malingerer, lest he should have the experience of an honorary surgeon who had walked into his ward one day and said to his house surgeon, "Well, Jones, and how are they to-day?" "All well," the house surgeon had replied, "except the malingerer in the corner, and he died last night."

A medical report should be in plain and business-like language. Insurance companies were neither interested nor impressed by technical terms. If technicalities must be used they should be put in brackets. Notes should be taken at the time of examination and preserved. In a difficult case the report should not be written until a few hours, preferably a day, after the examination. The proportional values were astonishingly different when viewed in perspective. Time should not be wasted labouring academic points of no practical utility. A report should not be biased by sympathy. Sentiment had its proper place, but was ill-matched in co-partnership with business. The late Sir George Savage had said that an opinion must be formed along one of two lines, one representing judgment and the other sentiment, but that those lines were parallel and never met.

The medical witness must not be surprised if it was insinuated in court that he was fundamentally ignorant of the elementary facts of his profession. He should take no notice. It was all a game, and he had better try to enjoy it. One piece of advice the speaker urged: when a case is lost, forget it and leave the solicitors to worry. The conscientious performance of one's duty in insurance work did not lead to an excess of popularity. The witness should never be afraid of admitting that he was not omniscient, but when the road bent abruptly he should take short steps. He should tell counsel with apparent candour that he was not a specialist; that a specialist knew everything about something, but that he had always aimed at knowing something about everything. This was not a clever statement, but it appeared so, and might help the witness round an awkward corner in the rough and tumble of cross-examination. Sometimes he would be asked whether a man was malingering, and would know that if he said "Yes" everyone in court would be angry. The best answer was that he had thoroughly examined the man, that it was true that he complained of many things, but that no physical signs could be found. The witness could truthfully say that he did not know whether this was a malingerer or not. It might then be put to him: "This man is not working and you say he is not a malingerer." The right answer would probably be: "He is really physically fit, but he requires that push towards usefulness which many men off work require. He is an irresolute individual, and would have a little inconvenience at first, which a reasonable man would put up with. He has not any real incapacity, but he has a feeling of inability caused by nervousness, all of which would be overcome by work. He is brooding over his recent injury, and the compensation he is receiving takes away the stimulus to work. Half-wages mean semi-starvation, and have a bad physical and moral effect." The witness should never go into the box without having had a radiogram of his subject taken, or he would be sure to be confronted with one taken by the other side.

Pain in the back was in most cases psychical, not physical. Nine-tenths of the subjective symptoms met with in trifling accidents were the result of auto-suggestion. The art was to determine how much was due to trauma and shock and how much to a perverted mental outlook. Neurotics who had had accidents were in much more need of treatment than was their traumatism, for they were facile and their thoughts ran along the lines of least resistance. The keynote to the successful treatment of a neurasthenic was to get the patient to make an optimistic inventory of his mentality. Re-education, both mental and physical, was the be-all and end-all of the cure. There was a definite relationship between the duration of an illness and the loss of the work habit; it was of the first importance to recommend return to work at the earliest possible date. Counter-suggestion was of infinite value, but if it was to succeed it must be immediate, forcible, continuous, and applied at the psychological moment. Suggestion was the art of getting an idea into someone's head without his knowing it. Everyone practised it daily—by manner, by facial expression, by mode of address, by self-confidence, and by clothes. Suggestion must not be put in a bottle. It could not, however, be practised as a duty; it was the work of an enthusiast. The man who threw himself into it, body, soul, and spirit, would succeed while half his neighbours were spending their time writing prescriptions for bromide of potash and the other half writing chits "to account rendered." Such men should take a holiday, for the doctor's holiday was the patient's opportunity.

Functional nerve disease was a combination of reality and unreality. It was like a battery with everything in working order and nothing lacking except the capacity to switch on the current. Many of these unhappy people might become chronic invalids or might return to work; the result depended entirely on the doctor. Very much more than was generally supposed depended on whether the doctor threw the weight of his personality into the diagnosis of traumatic neurasthenia and hysteria. His most valuable asset was a knowledge of human nature.

DISCUSSION

Sir BERNARD SPILSBURY said that the post-mortem room, like Sir John Collie, was a great revealer of malingering. Allegations were sometimes made in the coroner's court that death was connected with some previous accident, which had often taken place a long time before, and the alleged sufferer had drawn considerable sums of money in compensation. In other cases a relative suddenly remembered after death that the deceased had undergone an accident some years previously. In a very large

Laboratory Service and the General Practitioner

By ARNOLD RENSHAW, M.D., Director of the Laboratory of Applied Pathology and Preventive Medicine, Manchester. London: Humphrey Milford, Oxford University Press. 1932. Pp. 267. 10*s.* 6*d.*

THE object of this book is to interpret to medical men, be they general practitioners, specialists, or consultants, the application and meaning of laboratory work in clinical medicine. The scheme of the book is well designed, and few instances in which the laboratory can help the practitioner escape mention; one such omission which might be rectified in future editions is the failure to mention *Br. abortus* as a possible cause of prolonged pyrexia. Instruction on the collection of specimens are detailed and precise. In the section of blood grouping and matching, the author has adhered to the old numerical nomenclature instead of adopting that according to the presence or absence of the agglutinogens A and B. The numerical nomenclature has been the cause of much confusion in the past and might now well be forgotten. A word of warning about the danger inherent in blood matching or grouping tests performed by those not thoroughly conversant with laboratory technique might have been advisable.

Dr. Dan McKenzie supplies an introduction in which he wholeheartedly recognises that pathology is not the "handmaiden" of clinical medicine, but an integral part thereof. Far from wishing to keep the pathologist chained to his bench, he realises that in clinical work the best results are attained when there is direct touch between the expert pathologist and the patient. Dr. McKenzie hails the advent of the "physician-pathologist" with confidence in his power to aid in the advancement of medicine.

Tuberculose osseuse et osteo-articulaire

By ETIENNE SORREL, Chirurgien de l'Hôpital Trousseau, Ancien chirurgien en chef de l'Hôpital Maritime de Berck; and Mme. SORREL-DEJERINE, Ancien interne des Hôpitaux de Paris. Paris: Masson et Cie. 1932. Pp. 514. Fr.350.

THE Hôpital Maritime de Berck contains 1500 beds and during the period 1920–30 the authors and their collaborators collected as many as 10,000 cases of bone and joint tubercle, many of which they were able to watch from beginning to end. With this wealth of material on which to draw it is not to be wondered at that they have succeeded in producing a notable work, based upon the lectures which Dr. Sorrell gave to French and foreign surgeons, twice a year, during his eleven years' sojourn at the hospital. Of the four main sections the first is devoted to tuberculous osteitis, which includes spina ventosa of the small bones of the hand and feet, and central abscess; the second deals with tuberculous osteo-arthritis of the upper limb; the third with the lower limb; and the fourth with spinal caries. Having set themselves the ideal of making this an essentially practical book, they do not, when discussing pathological anatomy, describe post-mortem specimens, neither do they discuss whether the lesion starts in the synovial membrane or in the epiphysis. Whichever tissue is primarily affected both very soon become involved, and the question does not affect treatment. Such operative procedures as synovectomy are condemned as irrational and unscientific. The accounts of pathological anatomy, to which a good deal of space is allotted in each chapter, are studies of the progress of the disease from a radiographic point of view. The X ray pictures are abundant, beautifully reproduced, and show typical stages in almost every bone and joint in the body. Two fundamental principles appear to be recognised as guides to treatment: (1) epiphyseal cartilages offer considerable resistance to the spread of the disease, and (2) in the adult as opposed to a child a complete cure can never be anticipated.

As an illustration of the first-named principle the observations on tuberculous disease of the wrist-joint are of interest. The primary focus is said to be almost always a spina ventosa of one or other of the second, third, fourth, or fifth metacarpal bone, but never of the first, because the epiphyseal cartilage is proximal in the latter and distal in the former. Since the centres of ossification of the carpal bone appear irregularly between the ages of 1–6, and are not complete until 12, the cartilages of the carpal bone offer a resistance to the spread of the disease to the radio-carpal joint for a very long time. The disease therefore tends to remain localised to the carpal bone, particularly to the os magnum and unciform whose centres are the first to appear, and as a result 80 per cent. of these cases are cured with the preservation of good movement at the wrist-joint itself. After the age of 12, however, the wrist-joint soon becomes involved, and in order to avoid this, from that age onwards, the authors recommend excision of the carpal bone, which, they claim, gives good functional results. In the ankle-joint they advise operation at an even earlier age. Here the primary focus is in the astragalus, and it tends to spread to the ankle and sub-astragaloid joints. It is useless, they say, to waste time in prolonged conservative treatment, because the best that can be hoped for is a cure with a stiff ankle and a stiff foot. Consequently, as soon as a diagnosis is established and particularly if an abscess forms, they perform an astragalectomy, thus reducing the period of treatment and preserving useful movement at the new ankle-joint. For most of the other big joints they recommend conservative treatment until adult life, except in cases of juxta-epiphyseal abscess, which should always be operated upon early, so as to prevent the spread of the disease into the epiphysis and ultimately into the joint.

Though tuberculous disease is more destructive in the child, and greater deformities are apt to occur, it does, however, tend to get cured with a firm bony ankylosis. In the adult, on the other hand, bony ankylosis never occurs spontaneously, and there is a tendency for cavities to form containing sequestræ and tuberculous granulation tissue. This tissue may remain quiescent for years but may flare up acutely from time to time. Hence in all cases of primary adult tubercle, or the continuation of the disease from childhood into adult life, some operative procedure is recommended; broadly speaking, this usually means an ankylosing operation in the lower limb and excision in the upper limb. It is emphasised, however, that no such operation should ever be undertaken during the early stages of the disease, and that a period of at least six months' conservative treatment should precede it.

The chapter on spinal caries is of particular interest, because it includes a discussion on Potts paraplegia, a subject of which Madame Sorrel-Dejerine has made a special study. Two varieties are recognised; the commonest occurs early in the disease,

REVIEWS AND NOTICES OF BOOKS

Radiotherapy in Cancers of the Upper Air-passages

The Relative Value of Radiotherapy in the Treatment of Cancers of the Upper Air-passages. By W. DOUGLAS HARMER, M.A., M.B., F.R.C.S. London: John Murray. 1932. Pp. 85. 6*s.*

Mr. Douglas Harmer has performed a valuable service in publishing his Semon lecture of last year [1] in book form, for the subject matter of his address necessarily involves the use of numerous statistical tables which demand close study and are not easily to be digested during the delivery of a lecture.

The work gives details of the technique and results of radiotherapy, not only as practised by Mr. Harmer and his colleagues at St. Bartholomew's Hospital, but of workers in this subject all over the world, and deals with the treatment of malignant tumours of all parts of the upper air-passages. There is neither index nor table of contents, and the page headings do not indicate which region is under discussion, so that it is rather difficult to find rapidly the details about treatment of a particular organ. The statistics supplied do not readily lend themselves to analysis, but some of Mr. Harmer's opinions and conclusions may be mentioned. His insistence on the importance of early diagnosis and early treatment loses none of its weight by being a reiteration of an already familiar warning, and this applies also to his dictum that "under no circumstances must a cancer case be placed on a waiting list." He considers it very dangerous to damage these tumours by partial operations, or even to perform a biopsy until the patient can be radically treated; it is safer to remove a fragment by endothermy or after ray treatment has been given. He believes it is a mistake to use the thin filters of 0·5 mm. of platinum which have been in vogue, and finds it safer to employ filtrations of 0·6, 0·8, or even 1 mm., in order to prevent œdema, perichondritis, and late reactions.

In the treatment of intrinsic growths of the larynx Mr. Harmer, as is well known, is a pioneer of the application of radium by means of needles inserted through a fenestration in the thyroid cartilage; this has given him such good results that he no longer considers that it is ever necessary to remove these growths by surgery. As regards the anæsthetic, he employs gas and oxygen with a small amount of ether after grs. 3 of nembutal by the mouth, and morphia gr. ¼ with atropine gr. 1/100 hypodermically. Sepsis must be avoided at all costs; it is generally possible to prevent suppuration by closing the skin wound completely. Infected teeth should always be removed previously. The growth should never be damaged, care being taken not to cut through the perichondrium which surrounds it. Tracheotomy should not be performed if the opposite cord is movable and the glottis adequate; when in doubt the front of the trachea can be exposed and left ready for an opening if necessary. With these precautions he has had only one death after this operation in 47 patients. The results have been very good among those cases suitable for thyrotomy, which operation, it may be mentioned, also gives very good results; that it is less good among those suitable for laryngectomy, and still less in inoperable cases, is to be expected and accentuates the necessity of early diagnosis and treatment. The remainder of the book deals with the pharynx, palate, cheek, and nose and accessory sinuses. Numerous statistics are provided, and there is a good bibliography.

The monograph will be valuable to specialists in this field, and of value to all practitioners who meet with a patient suffering from cancer of these regions.

Les réticulocytes et les réticulocytoses

By Dr. C. M. LAUR, Préparateur Adjoint à la Faculté de Médecine de Paris. Paris: G. Doin et Cie. 1932. Pp. 160. Fr.35.

THE occurrence and behaviour of the reticulocytes in the circulatory blood has been closely studied in recent years. Dr. Laur reviews the early literature dealing with these immature cells in great detail, and also discusses fully the chemical and physical nature of the reticular substance. He concludes, as the result of his own experimental work, that the punctate basophilia of lead poisoning is a different phenomena from the reticulum of the young red cell, a conclusion which might be questioned by many hæmatologists. The pathological conditions, in which a transitory or permanent high reticulocyte count is found, are discussed, and many examples from the author's own case records illustrate this chapter. Unfortunately some important recent work is omitted. The type of curve found in microcytic anæmias in response to iron therapy is not discussed. Little stress is laid on the strictly quantitative nature of the reticulocyte response to adequate treatment in pernicious anæmia. The author certainly states that he has found it impossible to enter into all the details of recently published work, but it is disappointing to find a specialist who takes the trouble to write a monograph unwilling to present the common reader with an up-to-date analysis of his subject.

Quick Reference Book for Medicine and Surgery

Eighth edition. By G. E. REHBERGER, A.B., M.D. London: J. B. Lippincott Company. 1932. In 11 parts. 65*s.*

THIS large volume claims to be a clinical, diagnostic, and therapeutic digest of general medicine, surgery, and the specialties, culled "extensively and intensively from modern literature, and systematised." Diseases and disorders are arranged alphabetically in each of the 11 sections, and a thumb-index to each section facilitates quick reference. The compilation has been done single handed, and it is almost inevitable that an expert looking at the particular section that concerns him will find something to criticise—either some inaccuracy, or some information that is now out of date. But the fact that the articles under each heading do not bear the stamp of the expert will not distress the average reader, who will find here what he seeks—a concise note setting out essential points. The allotment of space is not always wise—for example, tables for finding the pH value of a solution would seem unnecessary in a book designed to meet the needs of a busy practitioner. But of the mass of information provided the greater part will be found useful at one time or another.

Reminders and Suggestions

For the
Treatment of
INFLUENZA, PNEUMONIA,
COUGHS, COLDS, BRONCHITIS, etc.

KINECTINE — An organic arsenical salt of Quinine indicated in Influenza, Acute Coryza, etc.

Tubes of 10 Tablets: Dose—One three times a day.

CRYOGENINE (Lumière) — A particularly safe and reliable analgesic and antipyretic in all febrile conditions. Bronchitis, Pneumonia, Influenza, Pleurisy

Powder and Tablets: Dose—From 0·50 to 2·50 gm. daily as required.

ORARGOL — An electrically prepared Gold-Silver Colloid for general antisepsis and effective colloidotherapy.

Ampoules of 5 c.c. and 10 c.c.

By intravenous or intramuscular injection Orargol is capable of aborting serious cases of Influenza and Pneumonia, and exerts an antitoxin-like effect in acute infectious conditions.

Also supplied in special O.R.L. Outfit for Nasal Irrigation in the treatment of Rhinitis, Tonsillitis and Naso-pharyngeal inflammations.

Extremely valuable as a prophylactic against the Common Cold.

SYRUP CREOSAL (Dubois) — A combination of Guaiacol, Calcium and Phosphoric Acid pleasantly flavoured with Syrup of Orange Flower & Cherry Laurel.

An excellent specific for Coughs—whatever their origin—Bronchitis, Laryngitis, and all Catarrhal Conditions.

SYRUP PERTUSSIS (Gabail) — A combination of deodorised Valerianate, expectorants and sedatives presented in a palatable form with Syrup of Raspberry.

An effective medicament for the Paroxysms of Whooping Cough.

reaches its maximum in a few weeks, and gradually, during the course of 18 months to two years, tends to improve under conservative treatment. The second variety appears late, is slowly progressive, and shows a tendency to exacerbations and remissions. The first variety is usually said to be due to compression by an abscess, but the authors prefer to make a distinction between paraplegia with an abscess and that due to an abscess. They maintain that the symptoms are often caused by circulatory disturbances in the cord, secondary to inflammatory reaction, with or without abscess formation, in close vicinity. In this way they explain the commonly observed phenomenon of increased knee-jerks and extensor plantar reflexes, in most cases of dorsal caries without any other compression symptoms. The second type of paraplegia is due either to a tuberculous meningitis, or to a kinking and destruction of the cord by a jagged piece of bone. For neither type do they recommend laminectomy.

It is difficult to speak too highly of this work. Whether or not the reader agrees with the point of view set out is immaterial. What the authors have to say is said remarkably well and is the fruit of long experience. It is said, moreover, in very simple French and within the understanding of those with only a modest knowledge of the language.

Alfred Fripp

By Cecil Roberts. London: Hutchison and Co. 1932. Pp. 288. With 14 illustrations. 15*s*.

This biography has been written at the request of his widow and is a personal chronicle of events and not a critical biography of a consulting surgeon. Sir Alfred Fripp revealed himself much in his diaries of which full use has been made, and the book derives its interest from the intimate comments which it contains upon the leaders in social circles of the Edwardian period. Sir Alfred Fripp was instrumental in raising very large sums of money for Guy's Hospital, and throughout his life showed his deep attachment to the foundation where he made his mark as an athletic student and taught assiduously for years, and whence he retired as senior surgeon after thirty years of consecutive service.

Die Nervenkrankheiten des Kindesalters

Second enlarged edition. By Prof. Dr. Georg Peritz, Berlin. Leipzig: Fischers Medizin. Buchhandlung. 1932. Pp. 688. Mk.39.50.

No less than twenty years have elapsed since the original edition of this text-book appeared, and it may be imagined to what extent a new edition must have required remodelling and rewriting; the author remarks in his preface that it possesses "ein anderes Gesicht." In its present form the volume embodies not a few matters of recent acquisition, such as the study of the capillaries of the nail-bed in relation to vasomotor neuroses and spasmophilia; acidosis in its bearing on various nervous phenomena and syndromes; new conceptions of hydrocephalus; "pink disease"; and others that need not be specified. The sections dealing with malformations and congenital defects are rather more detailed than is usual in books of the kind, and this is an advantage. Considerable attention is paid to the problem of the nervous child and to neuroses in childhood generally.

While there is abundant evidence of the skill with which recent increments to knowledge have been incorporated, it is surprising to find comparatively little notice taken of varieties of meningitis aside from those associated with tubercle and sepsis, and still less of the encephalitis accompanying many of the exanthems and other fevers of childhood. The articles on cerebral tumour and on epilepsy contain a mixture of old and new conceptions which is not altogether satisfying. Still as a whole this text-book is both compendious and accurate; it is well printed and illustrated, and there are some references to the literature in footnotes to the pages, though many more names are mentioned in the text than are thus particularised.

Handbook of Bacteriology

Third edition. By J. W. Bigger, M.D., Sc.D. Dub., F.R.C.P.I., D.P.H., Professor of Bacteriology and Preventive Medicine, University of Dublin. London: Baillière, Tindall and Cox. 1932. Pp. 459. 15*s*.

This text-book of medical bacteriology fills a useful place in the student's library. While giving a clear account of the bacteriological knowledge which he should require, Prof. Bigger has kept the size of his book within reasonable bounds. The new edition is only seven pages longer than the second, which appeared three years ago, and does not differ from it materially, most of the alterations being of minor importance. The book should retain its popularity, for, if dogmatic, it is accurate as well as concise.

Intracranial Suppuration

By E. Miles Atkinson, M.B., B.S. Lond., F.R.C.S. Eng., Surgeon in charge of the Ear and Throat Department, Royal United Hospital, Bath. London: Jonathan Cape. 1932. Pp. 127. 5*s*.

The Modern Treatment Series, to which this little book belongs, aims at presenting the generally accepted views on special subjects in a readable and concise form. This volume conforms to such an ideal. It gives a very fair account of intracranial sepsis based upon current medical opinion and on the author's own considerable researches. Mr. Atkinson rightly emphasises the earlier signs of intracranial suppuration, signs which at first may not be at all characteristic, but whose enumeration serves the very important purpose of suggesting to the practitioner that these diseases, rare in his practice, must not be entirely ignored. Short descriptions of operative procedures are also incorporated in this book. For those who wish to study the subject further or require more precise information on technique, excellent bibliographies are appended to each chapter.

Hints to the Young Practitioner

By G. Francis Smith, M.R.C.S. Eng., L.R.C.P. Lond., Consulting Surgeon, Peace Memorial Hospital, Watford. London: Oxford University Press. 1932. Pp. 156. 5*s*.

This is a wise little book. The chapters form suitable counsel to the young general practitioner. The advice given conforms with universal experience, and this of course makes much of the teaching obvious, but the precepts are so clearly arranged and the information is given in such a sympathetic manner that the author should find his work successful. He deals shrewdly with difficulties arising in the early days of general practice.

THE LANCET

LONDON: SATURDAY, NOVEMBER 5, 1932

RADIUM THERAPY

YEAR by year the reports from the research centres working with radium lent by the Medical Research Council are summarised in a green book issued by the Council, with appropriate comments from their Radiology Committee. The book in our hands (Special Report Series No. 174) is the tenth to be issued on this subject, and comparison with its predecessors shows that progress has been made on expected lines, though not so smooth and rapid as some had hoped. The first of the ten reports (No. 62) dealt with the initial therapeutic trials made when the whole stock of radium bromide collected for military purposes during the war, afterwards to be distributed between nine centres, was concentrated at the Middlesex Hospital.

The first summary of reports from the centres (No. 90) appeared in 1924, and dealt with work in progress in 1923. It is here recalled because, while disappointment had attended the use of radium in malignant growths of the mouth, jaw, and throat, the conclusion was already reached (p. 31) that in the treatment of cancer of the uterus radium is an agent of unquestionable value, and in cancer of the breast the increasing use of radium, combined with surgery, was already giving good results. It is significant perhaps of the growing complexity of the subject that whereas in 1924 the comments of the Radiology Committee were presented in the form of a conclusion to the summary of the various reports, in 1932 they are presented only as an introduction. But the main lines of radium therapy at the present time are still the treatment of cancer of the breast and the cervix uteri. The buccal cavity, however, is now placed among the more, instead of among the less, hopeful regions, though statistics reveal that the expectation of life of a patient with a primary growth of the tongue which has extended to the glands of the neck is still very low. A comparison between radium and surgery in this region can hardly be made, because present-day therapy consists largely of a combination of surgical and radiological methods; but it can at least be said that the mutilating operation of excision of the tongue has now given place to radium treatment. As to the breast, though the immediate mortality is very low, the results returned in these annual reports give the impression either that the expectation of dealing successfully with the inoperable breast cancer must not be placed too high, or that radiological methods for this site have not yet been fully explored. It is suggested that better results in this region may have to await a hopeful lead from experimentalists in radio-sensitiveness and radio-resistance. If, however, recent views on damage to endothelium as the true basis of the apparent selectivity of radium as used in treatment are confirmed,[1] little practical help can be expected from any attempts at differentiation which ignore this factor. At present most surgeons would go still further, and agree with Mr. B. W. WILLIAMS (see p. 1017) that early growths in regions in which operative treatment gives excellent results should not be subjected to treatment by radium alone unless for any reason operation is contra-indicated. If Mr. WILLIAMS's review of the present position of radium therapy in general seems unduly pessimistic, this impression was dissipated in the minds of those actually present at his lecture by the demonstration of a dozen successes in inoperable cases. His contention that radium treatment is still at a stage of empiricism is confirmed by the variations in technique adopted at different centres. As he says, principles are only emerging painfully and slowly, and all the rules being formulated appear to be subject to confounding exceptions. This is what makes the teaching of radium therapy so difficult, especially in view of the occurrence of occasional distressing complications which may or may not be attributable to radiation. For example, the Cardiff centre reports on 22 cases of fistula formation among the 254 cases of carcinoma of the cervix treated with radium during the last ten years. In none of these cases—all but one advanced and inoperable—did the fistula form immediately after treatment, but the conclusion that this delay precludes the possibility that they were due to it seems hardly justifiable. The University College Hospital report, which was published as a separate book last May, contains interesting notes on some sequelæ of irradiation, including pain and radionecrosis, acute and delayed, and on the effect of irradiation of the eye. Two cases of blindness following treatment were reported, neither being satisfactorily explained. Observations on cases in which radium has been applied close to the eye are being made, and the results will be discussed next year. At this hospital proctitis has been found to be far the most important sequela of irradiation for cervical carcinoma. Mild and transient attacks of proctitis are found to be very common and to be difficult to avoid if treatment is adequately carried out. Severe and lasting cases which make the patient miserable are happily less common; they are attributed to inadequate precautions to protect the rectum when the vagina is plugged. The General Hospital, Birmingham, draw attention to the dangers of the use of radium in unskilled hands in connexion with the radio-necrosis and delayed burning which may follow treatment of cancer of the buccal cavity, while an underdose appears sometimes to stimulate the growth. St. Bartholomew's Hospital, reporting on adenocarcinoma of the rectum, point out that in these growths the margin between a lethal dose and an overdose is small, and that success probably depends on an intensity of

to see that others, perhaps thousands of miles away, have been encountering difficulties similar to their own: to note how they have attacked them, and with what measure of success; to discover ideas new to them and try how far analogous measures may be applied in their own districts—these things are of untold worth in bringing men into closer contact, in making them feel their kinship through the touch of nature, and form a powerful incentive to renewed endeavour.

THE HEALTH OF THE MERCANTILE MARINE

FOR some years we have published annually in our columns an analysis of the statistical information regarding the deaths of seamen, issued by the Board of Trade in the Annual Return of Shipping Casualties to, and Deaths on, Vessels Registered in the United Kingdom.[1] It has been our object to call the attention of our readers to the general conditions of health, accommodation, and sanitation amongst the men of the mercantile marine, it being our belief that the care of the merchant seaman in these directions has not been of the same standard as that required amongst the population on shore; that although advances have been made on their behalf progress has been less rapid at sea than on land.[2] A more efficient care of the seaman's health would be secured, we suggested, by a transference of responsibility from the lay Board of Trade to the Ministry of Health. In this proposal we were in agreement with the Royal Sanitary Institute, whose view it was that both the compilation of mortality statistics and the care of the seamen's health should be entrusted to the Ministry of Health, a department especially organised for these duties.[3] Peculiarly welcome, therefore, was the appointment in 1928 of a standing Joint Advisory Committee of the Board of Trade and the Ministry of Health to advise the two departments on questions affecting the health of the mercantile marine. One of the problems to which this committee paid immediate attention was the provision of a statistical measure by which the health of the industry could be assessed, a measure which so far had been lacking except for the very inadequate statistics at the Board of Trade's disposal. The conclusion was reached that, while the preparation of complete morbidity statistics for the industry was probably impracticable, it was highly desirable that a thorough statistical investigation of the mortality of merchant seamen should be undertaken. Arrangements were made with the London School of Hygiene and Tropical Medicine to carry out this investigation on behalf of the Board of Trade, and the results are shown in a report prepared by Major P. GRANVILLE EDGE, of the statistical department of the school.[4]

A very careful attempt has been made in this report to reach accurate figures for the population exposed to risk, and the mortality that should be related to it. As regards the former, it was the opinion of the subcommittee of the Permanent Consultative Committee on Official Statistics[5] that "a very imperfect picture of the mercantile marine would be obtained by a contemplation solely" of the figures obtained in the Board of Trade's annual census of seamen, since this record supplies not the total numbers of seamen, but only those actually in employment on a given date. This subcommittee concluded that the most satisfactory figure would be obtained by taking the figures relating to the occupation resulting from the decennial census of the general population, and adding to these the figures supplied by the Registrar-General of Shipping and Seamen of crews "at sea" on the night of the general census; these two sets of data would provide the total population of seamen. Unfortunately it was impossible in this report to adopt this procedure, since the figures relating to the general census of 1931 were not available. The use of the figures resulting only from the annual census must have the effect of over-stating the mortality ascribed to sea service, since the population relates only to the employed on a certain date, while the deaths refer to the employed and unemployed during the year. To overcome this difficulty, methods of estimating the true population exposed to risk are introduced in the report and discussed at length. As regards the deaths, the numerator of the death-rate fraction, copies of all entries relating to the deaths of seamen, reported during the year covered by the investigation, were specially supplied by the Registrars-General of England and Wales, Scotland, and Northern Ireland. To every death certificate was added special information as to the man's employment, the date when he last went to sea, as obtained from the various official registers and indexes of seamen; if the deceased could not be traced in these registers, a letter of inquiry was addressed to the next-of-kin, informants of death, hospital and other authorities. In the light of this information a considerable proportion—as much as 16 per cent.—of the total deaths was excluded from those submitted to analysis. The excluded cases represented those where the declared occupation of the deceased person at the time of death was that of "seaman," but the man's service had either been confined to fishing vessels, barges, or other craft whose populations would not have been included in the annual census of seamen, or they were men who, for other reasons—e.g., foreigners on foreign ships—were outside the scope of the inquiry. These are among the elaborate precautions that have been taken in the endeavour to reach a true occupational death-rate. In spite of them the results reached can only be regarded as tentative, and it is admitted that this report is unable to provide a definite and final settlement of the problems of the seaman's health. If the 3620 deaths, included in the year's analysis, are related to the population figure obtained at the Board of Trade's annual census, a death-rate of 18·6 per radiation which only just avoids a radium "burn." In this connexion it may be noted that an ingenious applicator for use in the rectum, which is illustrated in the report, has been devised by the Scottish Association of the Medical Women's Federation.

[5] Statistics Relating to Health and Mortality in the Mercantile Marine. H.M. Stationery Office. 1926.

If attention is here drawn to the sections of this report detailing possible drawbacks to the use of radium, and to the lack of definite guidance in matters of dosage and technique, it is in order to emphasise the value of a correlating agency such as the Medical Research Council provides. The research centres under the Council now number 12, and the rapid development of radiotherapy is seen from the fact that the relative frequency of surgical and radiological treatment of cases of malignant disease presenting themselves at the ten centres supplying this information is about equal. Only by a critical examination of records and a tireless follow-up system, which takes count of morbidity as well as mortality, can the peculiar contribution of radium to medicine be applied to best advantage.

THE COLONIES IN BRIEF

FROM the time of inauguration of the Colonial Medical Research Committee in 1927, summaries of the reports of the medical departments of the various colonies, protectorates, and dependencies have been prepared for the use of officials. For the first three years the general information as to the health of the different territories was but briefly dealt with, the major part of the publication being devoted to the researches being carried on by officers of the Colonial Medical Service, together with an account of work on allied subjects by investigators of other nationalities. This was done with a view to keeping British workers abroad acquainted with the more recent advances in tropical research in various parts of the world, so that they might not waste time in repeating work already proved and accepted, and so that they might be saved the task of having to read for themselves papers often difficult of access and many of them in a foreign language. The last appearance of this work, printed for private circulation, was in 1930, when the Colonial Medical Research Committee was dissolved. Since then the issue of an annual supplement to the *Tropical Diseases Bulletin*, containing summaries of the full reports of the activities of the health departments, medical and sanitary, of the colonies, has been undertaken by the Bureau of Hygiene and Tropical Diseases, the actual task of preparing the summaries being in the hands of Dr. H. HAROLD SCOTT, the assistant director of the Bureau, who had previously been secretary of the Colonial Medical Research Committee. Two such supplements have now appeared, dealing with the annual reports for 1929 and 1930.[1]

For purposes of gathering together the vast amount of information contained in these annual reports they are dealt with in groups geographically—West African, East African, Mediterranean, Indian Ocean, the Far East, the Pacific Ocean, the West Atlantic, and South Atlantic—and the colonies, protectorates, and dependencies within each group are considered seriatim. The general plan, to facilitate reference and comparison, is to mention in order: vital statistics, maternity and child welfare, school hygiene, and general sanitation; under this last are included water-supply, conservancy measures, town planning, proposals for future work, and the like. Next follow clinical details giving accounts of hospital facilities, out-patient departments, dispensaries, urban and rural, with statistical and medical records of the chief diseases—e.g., malaria, dysentery, enteric, cholera, plague, leprosy, tuberculosis, yaws, venereal diseases, helminthic infestations, and so forth—and the measures for combating them. In each case, where possible, the figures in the returns for the previous year are given as affording an instructive comparison and an indication of progress or of the need for special investigation, study, and preventive measures. Lastly, summaries are given of the laboratory facilities and of the research carried out during the year, completed or in progress.

This collection of summaries is useful in several ways. First, they contain accounts of matters which are scattered through the larger reports, each extending perhaps to more than a hundred pages, but are here brought together so as to make a connected story and more interesting reading by revivifying the dry bones of the official records. Secondly, the vital statistical returns, giving the population as a whole and by race, the numbers of births, deaths, invalidings, and the causes of the latter, will be of undoubted value to actuaries and insurance officials at home and abroad who do a large amount of business in policies of insurance—life, health, and accident—amongst Europeans permanently resident in or temporarily visiting the colonies. Thirdly, they are a fruitful source of information to intending travellers abroad, telling them the commoner causes of ill-health in the districts they may be proposing to visit. Fourthly, they appeal to the research worker in that they refer to the many and varied investigations undertaken in the tropics, stating what is being attempted, what has been accomplished during the year, and the researches proposed for the immediate future. The more important of these, including matters of academic research, receive special individual notice in greater detail in the *Tropical Diseases Bulletin* or the *Bulletin of Hygiene* in the appropriate sections. Lastly—a point of no little significance—the issue of these supplements has already proved an encouragement to those working, often under trying conditions of climate and environment, sensible of loneliness, of the unavailingness of much of their efforts, or, what is even more galling, feeling that their work is not appreciated. For them to know that their official reports are not relegated to oblivion but are scanned, studied, abstracted, and widely published;

[1] Trop. Dis. Bull., Suppl., 1931, xxviii., pp. 68. 2s. 6d.; ibid., Suppl., 1932, xxix., pp. 148. 2s. 6d.

it can be said with greater truth or force that his work is cited and utilised to an ever-increasing extent because of its value as an aid to understanding problems of symptomatology and pathogenesis in nervous disease. His decerebrate rigidity of the laboratory has become a bedside commonplace; his reciprocal innervation has illumined varieties of involuntary movement: his conception of integration has enabled the neurologist to correlate phenomena of disease whose significance otherwise would have remained obscure. SHERRINGTON's position is indeed unique, seeing that he has laid under indebtedness to himself for insight into clinical difficulties a host of workers whose field of activity does not correspond with his own. It is meet, therefore, that our premier neurophysiologist, ripe in years and knowledge, should receive from abroad that public tribute which does no more than echo what has long been thought of him in this country by all who know him or his work.

Prof. ADRIAN has followed somewhat similar lines of research, and his career has been one alike of fulfilment and of continuing promise. He has specially occupied himself with investigations on sensation and the sensory system, and long since won his spurs by many contributions of enduring merit. He has attracted numbers of younger men to work with him, so that the Cambridge school of neurophysiology bids fair to rival that at the sister university as a centre of the keenest activity in advancing physiological knowledge. Adrian has always shown a lively interest in clinical neurology and had the opportunity of prosecuting clinical research during the war. Thus it comes about that he also has been the maker of studies which have a direct bearing on problems of a clinical kind.

ANNOTATIONS

SOME BACTERIOLOGICAL PROBLEMS

THE Harben lectures which are given each year at the Royal Institute of Public Health do not get the audiences which their quality deserves, and we should have expected that more people would have welcomed the opportunity of hearing such a distinguished bacteriologist and hygienist as Prof. Max Neisser, of Frankfurt, when he came to talk out of his accumulated experience about new light on some of the old problems of his science. His name, at any rate, must be familiar to many thousands of medical students who have attempted, and sometimes achieved, his method of staining the diphtheria bacillus, for it is not only a useful procedure, but one which produces elegant and numerable microscopical preparations. In his first lecture Prof. Neisser dealt with the variation of bacteria and the possibility of the transmutations which have been so often described. We know now, he said, that bacteria are more variable than we used to think, and that the varieties of one species may show quite striking differences; we attach less importance to small aberrations from type, and we are more sure than ever that what may fairly be called a "species" has never been observed to change into another "species." Bacteria have not provided us, as was at one time anticipated, with the spectacle of evolution going on before our eyes, and the history of the claims to have seen it shows that sound bacteriology rests, now and always, on a rigorous technique.

This is the lesson also of the second lecture, in which Prof. Neisser discussed the acid-fast bacilli which resemble the tubercle bacillus. That similar looking, non-pathogenic bacteria were rather widely spread about the world has been known for a long time, but their prevalence and abundance has only recently been realised, and they are evidently more of a trap for the unwary or hasty bacteriologist than has generally been thought. The slime in the orifice of any metal water tap anywhere will show large numbers; they can easily be grown in pure culture and are quite harmless to animals. The nature of the water makes no great difference, and even chlorination does not kill them. Their bodies may obviously be found in any media made with tap water, just as microscopical preparations off gelatin media may show the bacteria which flourished in the putrefying bones of origin. The metal mouthpieces of wind instruments of music are also a favourite haunt of similar (probably the same) microbes, which presumably get there from the mouths of the players, whither they come from water. It is evident that anything looking like the tubercle bacillus which is found in an unlikely place needs thorough cultural and animal tests before its pathogenic character is assumed.

The favourable differential environment provided by metal taps for acid-fast bacilli leads on to the third discourse on the bactericidal effects of silver. These have been known since Naegeli's original systematisation of "oligodynamic" action, in 1893, in which he showed that extremely small concentrations of copper and other metals were poisonous to spirogyra and other lowly life. His supposition that chemical action was impossible and that some new destructive influence had to be invoked has proved unnecessary; it seems clear that a sixpence placed in the middle of an agar plate prevents bacteria growing in its neighbourhood, because traces of silver oxide and carbonate go into solution, and quantitative calculations show that it needs about 20 million silver ions to kill one colon bacillus. At the boundary of the area in which there is a killing or inhibitory concentration of silver, the growth of the organism is enhanced—an elegant illustration of the general rule that poisons, if they are weak enough, stimulate cell growth. This fact qualifies the possibilities of using silver on a large scale for cleaning water-supplies, though the technical difficulties appear to have been surmounted, and the quantities of silver necessary are far less than those which may be safely injected intravenously in man.

CRAFTSMANSHIP WITHOUT SIGHT

THE numbers of men who come under the care of St. Dunstan's have not yet begun to decrease: although there were 31 deaths during the past year, 33 new cases have been admitted, men whose sight has ultimately failed as a result of war service. Their training fits these men to take posts which at first sight would appear to be quite beyond the scope of the blind. Many become joiners, learning to handle their tools with precision, and producing finished articles which compare favourably with the work of

1000 is reached for all classes (British, Lascars, and foreigners), and 24·8 per 1000 for British seamen alone, the population used relating only to the employed on a given day. Using estimated populations the mortality-rate at ages 20 and over is given as 16·04 per 1000, as compared with 17·61 for males in all England and Wales in 1929; at ages 20–65 it is 9·87 per 1000, compared with 9·70 for all males; but crude rates such as these are, as Major Edge points out, of limited value as indications of the healthiness of the mercantile marine, for the age distribution of merchant seamen must differ very widely from that of the general population. As an alternative standard of comparison the statistics of the Royal Navy have been utilised, and the following reasonably comparative results have been deduced.

—	Mercantile marine. Population 162,656	127,518		Royal Navy. Population 86,240	
Cause of death.	No. of deaths.	Rate per 1000.	Rate per 1000.	No. of deaths.	Rate per 1000.
Disease ..	295	1·81	2·31	153	1·77
Injury ..	109	0·67	0 85	49	0·57
Drowning ..	205	1·26	1·61	42	0·49
Suicides ..	31	0·19	0·24	9	0·10
All causes ..	642	3·95	5·04	254	2·94

But merchant seamen have not continuous service, and any dying when unemployed are, technically, "retired" and are not shown in the above figures, a point made by Fleet-Surgeon Home in an article on the Report which appears in this issue (p. 1020).

Two estimated populations, it will be seen, have been used in computing the rates for the mercantile marine. The lower must err in the direction of over-statement of the death-rates, the larger errs in the direction of under-statement. From these rates Major Edge concludes that "bearing in mind the widely differing conditions of service characterising employment in the Navy and mercantile marine respectively, the higher mortality-rates due to 'All Causes' and to 'Disease' in the latter are not excessive, nor are they higher than might have been anticipated." Further consideration of the *causes* of death in the mercantile marine has been made by means of the method of proportionate mortality—i.e., the proportion of deaths that particular causes contribute to the total mortality. The method has serious drawbacks, but in the absence of accurate population statistics it is probably the best that can be adopted. In this way seamen have been compared with those following shore occupations in which a high standard of physical fitness on the part of the workers employed is demanded—e.g., coal-miners, agricultural labourers, dock labourers. In 1930 for the very first time, the deaths in the merchant service by injury, 316, were fewer than those by disease, 370, and the report generally is a careful and valuable attempt to reach conclusions regarding the peculiar problems of the health of the merchant seamen. It has certainly taken us a step further in solving those problems, and it has shown clearly the intricate technical difficulties involved. It makes no pretensions to be complete; in fact, Major Edge urges that the whole scope of the inquiry must be widened if dependable conclusions are ever to be reached. The census figures of 1931 will assist in removing some of the conjectures that have at present to be made with regard to the population exposed to risk; data relating to a longer period of time than a single year will place the mortality figures on a more secure basis. Major Edge says: "So far as can be ascertained, no maritime nation has ever yet engaged in an extended and searching inquiry into the mortality of her merchant seamen. The mercantile marine represents our most important commercial undertaking and, as the leading maritime nation of the world, we should lead the way in this field of work." It is gratifying to find this attitude replacing what we have hitherto regarded as a lack of attention to the important problems of the seaman's health. We trust that this inquiry will be the precursor to the comprehensive investigation that Major Edge envisages.

◆

NOBEL PRIZEMEN

The announcement by the Royal Caroline Medico-Surgical Institute in Stockholm that the Nobel Prize for 1932 in medicine and physiology has been awarded jointly to two English physiologists—Sir Charles Sherrington and Prof. E. D. Adrian—will be received with pleasure and gratification by very many scientists and professional men outside the narrower circle that is thus directly honoured.

Forty years ago Sherrington's name was already known as that of one who had made his mark by contributions to the physiology of the nervous system, and successive decades have witnessed a rich output of studies that have seemed to delve ever farther into the mysteries of neural action. Highly technical though they have nearly always been—for Sherrington has never assumed the rôle of a popular expositor of physiological complexities, nor cared one iota for the physiology-made-easy of some of his contemporaries—it is a remarkable tribute to his genius and personality that no one has ever wished it otherwise. Those who have sat at his feet, at Oxford and elsewhere, have sought to emulate his level of accomplishment, and have endeavoured to imbue themselves with his spirit of research. His classical work, "The Integrative Action of the Nervous System," published in 1906, takes some reading, and those who have mastered its closing chapter on sensual fusion and binocular flicker, have reason to congratulate themselves on the achievement. That Sherrington has laboured for a lifetime at neurophysiological problems without paying much specific attention to the clinical applications of his discoveries and advances is another remarkable feature of the man; disclaiming all acquaintance with clinical neurology, he has been content to carry the torch of pure science. And yet there is no one to-day of whom organs. It is necessary to protect the whole body against these gases, and those treating victims are handicapped by the necessity of protecting themselves against the residue of the gas on the skin and clothing. It is very dangerous to treat these cases in a confined space or to bring their clothes indoors. If taken in time, mustard gas can be quickly washed off with bleaching-powder solution, soft soap, peroxide of hydrogen, or permanganate of potash. but if left in place it is steadily absorbed.

While it is possible to organise effective protection against all poison gases at present generally known, the efficacy of the measures depends entirely upon the knowledge of the leaders and the discipline of the population for whom they are responsible. Organisation of the civil population in Germany, according to a paper appearing elsewhere,[2] is achieved through three main groups the "Technische Nothilfe," the Red Cross sanitary columns, and the corps of fire engineers. The first of these is used to assist industrial enterprises overcome by fire or flood, and gives practical and theoretical instruction to their personnel. The Red Cross columns number over 3000 and include over a quarter of a million members; they are familiar with poison gas dangers because of the great extent of the chemical industry in Germany. The fire engineers are a highly trained and versatile organisation plentifully supplied with apparatus. A large number of firms manufacture gas masks and are striving to improve their models; advances are being made in the use of changeable filters to protect against different kinds of gas. Notice of the approach of aircraft is said to be closely organised over the whole of the Reich, and every centre of population should in practice receive ample warning. The production of artificial cloud screens, for protection and for warning alike, is being studied. Popular education is carried out by the Deutsche Luftschutz-Liga, which unites the efforts of the technicians and the civil population. Every citizen may be a member for a small yearly subscription. Several periodicals exist dealing exclusively with protection against aero-chemical attack, and last year the Auer Society held an instructive demonstration in Bremen, in which many voluntary bodies took part.

TUBERCULOUS BACILLURIA

THE question as to whether tubercle bacilli can be excreted by a normal kidney is clearly one of practical importance. It was at one time assumed that the appearance of tubercle bacilli in the kidney urine was of similar significance to their demonstration in the sputum in proving disease of the corresponding organ; but the number of cases recorded in which a kidney was removed in which no characteristic tuberculous lesions could be found threw doubt on the theory. It was then argued by some observers that the normal kidney must be permeable to tubercle bacilli circulating in the blood stream, although the experiments of W. Wyssokowitsch, C. v. Klecki, and J. Koch [3] [4] [5] had shown that the rapid disappearance of injected tubercle bacilli from the circulation which occurs is effected primarily by their lodgment and destruction in the spleen, liver, lungs, and bone-marrow, and not by their excretion by the kidney. Others concluded that the organisms could only pass through a kidney already damaged by chemical or other trauma, and others again that tubercle bacilli could produce non-specific inflammatory changes in the kidney (tuberculous nephritis). It was widely held that removal of such an organ was contra-indicated, although excretion of the organisms might subsequently lead to their attacking the parenchyma of the kidney. The process of excretion without recognisable lesion was known as Ausscheidungstuberculose ("excretion tuberculosis"). F. Lieberthal and T. von Huth [6] have recently reviewed the experimental literature which is principally concerned with the demonstration of tuberculous changes and presence of the organisms in the kidney tissues rather than with their appearance in the urine, and have contributed an experimental study of this latter aspect of the problem. They injected suspensions of tubercle bacilli into the ear vein or left ventricle of female rabbits, giving in some cases intravenous glucose or subcutaneous saline to promote diuresis. The total urine excreted was collected over 24-hour periods, and the animals were killed after a varying number of days. Each urine specimen was examined for tubercle bacilli in the direct smear, and by culturing according to the Loewenstein-Sumyoshi method on Hohn's egg medium. In certain of the animals cantharidin nephrosis, uranium nephritis, and mercurial nephrosis of varying severity was induced before the injection of bacilli was carried out. A careful post-mortem examination of the kidneys was made in each case for tuberculous and non-tuberculous renal damage, and for the presence of organisms. The authors conclude, from the correlation of their own and previous histological and urinary findings, that a physiological excretion of tubercle bacilli by the normal kidney does not occur, nor do they believe in the existence of either the so-called tuberculous nephritis or of true excretion tuberculosis—i.e., organisms being excreted by the kidney then attacking its substance. However, a "false" excretion tuberculosis, in which spread of an interstitial tuberculous lesion through the wall of a tubule or glomerulus, resulting in the appearance of tubercle bacilli in the tubules and subsequent infection by them of other parts of the kidney, may in their view occur (though rarely). In their experiments the production of non-tuberculous renal damage before the injection of tubercle bacilli did not render the kidney permeable to the organisms, but as in P. Baumgarten's [7] experiments with ligation of the ureter, such damage appeared to favour the development of true renal tuberculosis. In common with previous workers, the authors find that the kidney shows a striking immunity to the presence of tubercle bacilli in the blood stream, which they attribute to its copious blood-supply and the large calibre of its vessels and conclude that infection, when it occurs from this route, is due to local disturbance of the circulation or the presence of tubercle bacilli in masses sufficiently large to result in embolism—e.g., when suspended in fat droplets or adherent to debris. The fact remains that when, in opposition to orthodox surgical views in this country, one of two kidneys, both excreting tubercle bacilli, has been removed, the patient's condition has occasionally improved to an astonishing degree. The criterion of infection in certain continental clinics has been the excretion of pus as well as tubercle bacilli, and when pus and tubercle bacilli are excreted from one ureter, and bacilli alone from the other, the former is removed, every effort men in possession of their sight. When training is complete St. Dunstan's takes the responsibility of setting up the blind worker in his own workshop, and a technical instructor visits him at intervals to advise on his work and recommend improvements. Blind craftsmen become ingenious at circumventing their disability; one man, having made a standard lamp, and being unable to direct a drill, split the stem of the lamp from end to end, cut a groove to hold the flex, and joined the halves again. A certain number of men take up massage and find that confidence in their skill is quickly acquired by patients; an expert from St. Dunstan's helps the masseur to keep his apparatus in perfect condition, and gains the coöperation of local doctors and hospitals in finding work for him. Other men become switchboard operators employed by large firms with many incoming calls; a specially constructed switchboard is necessary of course. These operators become highly skilled, and several firms have found the work performed more efficiently by a St. Dunstan's man than by an operator in possession of his sight. Poultry farming, boot-repairing, and basket-making are among other forms of work taken up by patients of St. Dunstan's. Those who had received little education before the war are taught English, composition, and grammar, as well as Braille reading and writing. Organised sports hold an important place in training, the men taking up rowing, swimming, shooting at goal, road-walking, and even skating. The patients take part at dances, to the music of a band composed of St. Dunstan's men.

AMBULATORY TREATMENT OF LEG FRACTURES

THE unpadded plaster cast is at present enjoying a period of great popularity among orthopædic surgeons. A traction apparatus for fixation of the leg during the application of a plaster cast for fractures of the tibia and fibula has been designed by Mr. R. Watson Jones, and was recently described by him at a meeting of the British Orthopædic Association.[1] The apparatus can be readily transported, and fixed at will to any firm table; it seems both simple and efficient. The apparatus consists of a thigh support, an L-shaped traction bar, and a clamp by which these two parts can be fixed to the table edge. The thigh lies on its support, with the leg hanging vertically over the end of the table. Traction is maintained by means of a pin driven through the os calcis, and a stirrup which hooks to the horizontal limb of the traction bar. Coarse and fine adjustments allow the correct degree of extension to be applied, and the limb is held firmly in position while it is encased in plaster from the knee to the base of the toes. A sorbot rubber heel is incorporated. Angulation is corrected during the application of the plaster by pressure of the operator's hands. The pin is withdrawn from the os calcis immediately the plaster is firm and the plaster continued to the upper thigh; the patient is allowed to walk from the second or third week. In compound fractures weight-bearing is commenced when the wound is dry. The technique Mr. Watson Jones uses for infected fractures is essentially the closed method of treatment described by Winnett Orr. Recurrent œdema is controlled by support of the leg by a "viscopaste" bandage, without massage.

Objections which have been made to the use of plaster-of-Paris in the immediate treatment of fractures of the lower limb have been based either on lack of faith in the plaster to prevent recoil of the fractured ends within the cast, or on fear of the trophic disturbances that might occur through interference with the circulation, or through blistering of the skin under the plaster. A certain amount of recoil does apparently occur in the method here described when the extension on the stirrup is released; in one case this was sufficient to cause a pressure sore on the dorsum of the foot. No case is, however, recorded in which overlapping of the fragments of the bones subsequently occurred. In fact, this pressure sore on the foot was the only complication met with in over 100 cases treated. A window is now cut in the plaster over the dorsum of the foot to prevent pressure on this area of skin. Swelling of the limb and blistering of the skin Mr. Watson Jones considers to be directly due to lack of support; he argues that the objection on this score to the employment of the skin-tight plaster is fallacious, as the plaster acts as an efficient external splint. He has met with no case of impairment of the circulation sufficient to warrant removal of the plaster. Several reproductions are given of X ray photographs showing the excellent immediate reduction obtained by the method. There seems no doubt in Mr. Watson Jones's mind of the great importance of early weight-bearing. Other surgeons are obtaining good results, both as regards alignment and rapidity of union, by treating the patients in bed.

PROTECTION AGAINST POISON GAS

IT is a commonplace to foretell that in any future war determined attempts will be made to intimidate civilian populations by the gas bombardment of cities by aircraft and artillery. The Government of East Prussia, which is entirely surrounded by potential enemies, regard this danger as a very real one, and the Königsberg Association for Scientific Therapy recently held a conference of medical and technical experts[1] which was attended by large numbers of medical men who wanted to prepare themselves to organise the civil population against possible gas bombardment. They learned that the gaseous products of high explosive shell, being lighter than air, are not very dangerous, and that the "blue cross" group—lacrymatory and sneezing gases—are dangerous only when they compel the victim to take off his gas-mask in the presence of deadly vapours. The "green cross" group includes compounds which irritate the lungs, such as chlorine, phosgene, and chlorpicrin; these can be combated by ordinary gas-masks, but if they are inhaled they cause acute œdema of the lungs and air-hunger, with a grave secondary danger of damage to the heart. For this reason artificial respiration is contra-indicated, and the best methods of first aid are venesection and the inhalation of oxygen. The serum lost from the blood should be replaced with saline, and the heart stimulated with strophanthin and glucose. The "yellow cross" or mustard gases, which are composed of dichlorethylsulphide, are by far the deadliest. They are actually fluids, but are atomised by explosion and hang about in thick clouds for a long time, forming a film on solid objects and impregnating clothing. The vapour is almost imperceptible at first, but after an hour or two it exerts a severe caustic effect on the skin and mucous membranes, with consequences that are often disastrous. Apart from its direct effect on the epidermis, eyes, and lungs, it is absorbed by the blood, and causes hæmorrhages in the brain, kidneys, and internal work. In his remarks on the nature of these viruses he still shows disinclination to accept the view that they are probably micro-organisms; in fact, he issues a warning against the too ready acceptance of presumptive evidence. An open mind is an invaluable asset in research, but in the case of such viruses as vaccinia, fowl-pox, psittacosis, and ectromelia, the recently acquired evidence points strongly to their micro-organismal nature. Any other view of them seems, at present, to require assumptions for which there is no warrant.

THORIUM IN RADIOGRAPHY

THE day when the scope of radiography was limited by the natural opacity of the organs is long since past, and now almost every year sees the discovery of some new method by which another organ may be rendered artificially impervious to the rays. In the last two or three years experimental work has been done in Germany and elsewhere on the use of thorium salts to render the liver and spleen more opaque to X rays. The method by which colloidal thorium renders visible the liver and spleen is shortly as follows. Colloidal thorium, like any colloidal suspension, is rapidly stored in the reticulo-endothelial system of the organism, and as it is not penetrable by X rays will therefore give a shadow of the organs in which it is stored. The mammalian liver and spleen, being very rich in reticulo-endothelial cells are thus outlined in the X ray picture. To the observations already noted in our columns[1] may be added others that have since been published. Fischetti[2] has found it possible to visualise the placentæ of the rabbit and guinea-pig with intravenous injections of Thorotrast (colloidal thorium dioxide). In the rabbit quantities of the salt far in excess of those required to show up the liver and spleen were required, and the animals died soon after their administration. In guinea-pigs the placental image was clearly photographed, the shadow first becoming apparent a quarter of an hour after the injection and being most intense three-quarters of an hour afterwards, then gradually lessening and finally disappearing at the end of 24 hours; all the lobes of the placenta were clearly delineated, and in one photograph the maternal vessels could be seen entering and leaving the organ. The liver and spleen also were rendered opaque to the X rays, but the time relations of these opacities were different, since they did not appear till four hours after the injection and persisted for some days. These differences are explained by the fixation of the opaque colloidal salt Histological examination of the viscera post mortem shows the reticulo-endothelial cells of the liver and spleen to be full of thorium granules. The reticulo-endothelial cells of the placenta, though by no means negligible in number, contain but few granules of thorium, and it thus appears that the placental shadow is largely the result of the great vascularity of the organ and the concentration of the salt in the blood plasma. Other histological findings suggest that the thorium does not pass the placental barrier and does not reach the fœtal tissues, but the results are of no clinical significance at present since they are obtained only at the cost of the animal's life.

R. Gottlieb[3] in Canada has used thorium clinically with success for delineation of the liver and spleen and of the pulmonary arterial tree. The dose necessary is minute compared with those required to produce a placental shadow in animals. Thorotrast was given in doses up to 25 c.cm. to 12 patients, most of whom were suffering from incurable diseases, and in several of whom death was imminent before the injection, and also to two normal persons. There was a complete absence of any immediate untoward effect, and although death occurred in six cases within a few days or weeks, it could not be attributed to the injection. Subsequent observations over a period of eight months have not shown any pathological changes in the organs in which thorium was deposited, in spite of slow elimination.

CHLOROFORM CAPSULES

THE offer of the National Birthday Trust to supply chloroform capsules for trial by medical practitioners on women in labour should not be ignored. The public demand for alleviation of the pains of normal labour is growing, and this device is the most promising attempt we have yet had brought to our notice to provide an analgesic suitable for use by the midwife in the absence of the doctor. Doubts have been expressed on the one hand whether the concentration of chloroform might not reach dangerous limits, and on the other whether the quantity (20 minims) supplied in each capsule can do more than act as a placebo. The only way to settle these questions is to make observations on a number of cases under widely differing conditions, and no better means of obtaining information could have been suggested than the enlistment of the coöperation of hospitals and practitioners.

THE next session of the General Medical Council will commence at 2 P.M. on Tuesday, Nov. 22nd, when the President, Sir Norman Walker, will take the chair and give an address.

AT a meeting of the Pharmaceutical Society of Great Britain, to be held at the Society's house, 17, Bloomsbury-square, London, W.C., at 8.30 P.M., on Tuesday, Nov. 8th, Dr. C. H. Hampshire, secretary of the Pharmacopœia Commission, will speak on the British Pharmacopœia, 1932.

Sir Bernard Mallet, who died on Oct. 28th at the age of 73, was Registrar-General for England and Wales from 1909–20. These were years in which vital statistics became of pressing national interest, and Mallet's grasp of economic theory enabled him to apply his figures to political and social conditions of the time. After his retirement from the Central Statistical Bureau he became president of the Eugenics Society.

Dr. William McLean, who is leaving England this week to become head of the Jerusalem Hospital of the Church Mission to Jews, has accepted the Royal Geographical Society's invitation to join the Mount Everest expedition next spring. He is 33 years of age, and was educated at Repton, King's College, Cambridge, and St. Thomas's Hospital. Before taking up general practice in London he was for some time the resident medical officer of St. Thomas's Home. It will be recalled that the medical member of the Everest expeditions of 1922 and 1924 was Mr. Howard Somervell, F.R.C.S., now surgeon to the London Mission Hospital at Neyyoor, Travancore.

being made by heliotherapy and suitable diet to raise the patient's general resistance. Whatever the pathology involved, that success has attended such drastic measures is certain.

DANGEROUS DRUGS AND THE ECONOMIC CRISIS

As foreshadowed in our issue of Sept. 17th (p. 640) the traffic in opium and other dangerous drugs came under review by the Council and the Assembly of the League of Nations at their recent sessions. The report of the Permanent Central Opium Board for the year 1931 was discussed by the Council on Sept. 23rd. It expressed regret that under the stress of economy it had omitted its April session, and thus, to some extent, was precluded from keeping that "continuous watch of international trade" which it was instructed to observe. Attention had been given to the additional work which will fall upon the Board in the event of the Limitation Convention of 1931 receiving ratification and coming into force. Certain gaps in the Convention of 1925 will, it is hoped, be filled up under the provisions of the later treaty. Regret is expressed that many countries have failed to furnish statistics as to dangerous drugs produced, imported, or remaining in stock, or as to the seizures of illicit consignments during 1931; such default in international obligations is regarded as "a matter of grave concern." The Board concludes from the statistics vouchsafed that there has been a continuous decrease in the total world manufacture of morphine, heroin, and cocaine since 1929. It has, however, to be remembered that no returns have been received from Turkey or the Union of Soviet Socialist Republics, which are large producers of some of the drugs in question. The total present world requirements of these drugs for legitimate medical and scientific purposes was, it will be remembered, estimated by the Limitation Conference to be 9 tons of morphine, 2 tons of heroin, and 5½ tons of cocaine. In Great Britain there has been a considerable decrease in the manufacture of morphine and heroin during the last three years, and some increase in the production of cocaine. As regards consumption in Great Britain, morphine appears to be largely replacing that of opium. Seizures of illicit drugs in the case of morphine, heroin, cocaine, and Indian hemp show a diminution in 1931, but the Board reports that these figures afford "no true indication of the extent of the illicit traffic," while the seizures of raw opium "rose from 1279 kilograms in 1930 to no less than 10,166 kilograms in 1931." The conclusion is fully justified that "the quantities of narcotic drugs manufactured are still vastly in excess of those needed for medical and scientific requirements."

The fifth committee of the League also reported to the Council and the Assembly and expressed concern that no more than six States had, up till Oct. 11th, ratified or adhered to the Limitation Convention of 1931, and urged the dilatory States to proceed to immediate ratification. Reference was made to the Bangkok conference and the objection of the Chinese to the Government monopoly system in the Far East. It would appear that the provision of the Hague Opium Convention of 20 years ago, which contemplated the total suppression of opium-smoking, will long remain unrealised. The advisory committee was reported to be making preparation for the projected conference on limitation of the cultivation of the opium poppy and the coca leaf. The Indian delegate reiterated the view that the *non-medical* use of opium should be deemed legitimate, and a similar plea for the like use of the coca leaf was voiced from Bolivia. The fifth committee concluded with the rather surprising claim that "the opium conventions are more universally applied than any of the other conventions negotiated through the League." Faced with the illicit traffic which is admittedly "still so large," they insist that despite the economic crisis "any faltering might aggravate that very crisis."

UNIVERSITY OF DURHAM: THE NEWCASTLE COLLEGE OF MEDICINE

THAT there is great discontent in the Newcastle College of Medicine has been for some time an open secret, and the move to dispense with the services of Prof. H. J. Hutchens, Heath professor of bacteriology and pathology, in very debatable circumstances, brought some of the questions at issue to the brink of legal proceedings. These were, however, stayed on the understanding that the administration of the College should be submitted to inquiry, and the facts were laid before the Chancellor, Lord Londonderry, in June last. On Oct. 28th the Governors of the College met to consider a letter from the Chancellor, in which he stated that in his opinion an independent inquiry should be instituted, and he asked for the assistance and coöperation of the Council of the College of Medicine in the course which he decided should be taken. A resolution was passed, by 53 votes to 28 against, in favour of an inquiry to deal with the whole field of the administration and constitution of the College, the College defraying the costs.

FILTRABLE VIRUSES AND DISEASE OF THE NERVOUS SYSTEM

POSSIBLY in no field of microbiological research is coöperation between clinician, pathologist, and laboratory investigator more essential than in the case of the filtrable viruses. This is not difficult to understand, for the size of the filtrable viruses is such that direct observation of them is either impossible or of limited assistance only; the changes produced by them in the host's tissues must, of necessity, be our principal source of information. In a recent paper T. M. Rivers[1] lays stress on the interest which this group of viruses has for the neurologist and neuropathologist. Quite apart from such conditions as acute anterior poliomyelitis and epidemic encephalitis, there is the added importance of rabies virus for human pathology as evidenced by recent occurrences in Trinidad and elsewhere,[2] and that important and elusive problem of post-infection encephalitis. This last condition, which incidentally can occur without any preceding infection, appears to be linked up with conditions such as disseminated sclerosis and Schilder's disease, since the histological picture presented by the central nervous system in all these diseases has a common feature—demyelinisation. Thus the elucidation of the ætiology of any of the forms of post-infection encephalitis might conceivably supply the key to the whole group and bring a rapid advance in our knowledge of these conditions. Rivers has no new light to throw on this problem, his object is rather to review the situation and clarify ideas as a prelude to further

Treatment.—There is no one treatment which is efficient in puerperal sepsis, but in recent years one striking fact stands out, that patients with this condition do infinitely better in an institution where they can be properly nursed and properly fed, and where treatment (such as it is) can be applied. The different results in patients nursed under these conditions and in their own homes are most noteworthy. Surgical treatment, whether it be hysterectomy, removal or tying of the ovarian veins, only adds one more strain with which the patient has to struggle. The intravenous and intramuscular injection of antiseptics is equally valueless. The least dangerous is flavine, 1 in 1000. Quinine by mouth and intramuscular injection has on the whole been disappointing. Vaccines and sera have not given the results one might expect. There is no doubt that blood transfusion and immuno-transfusion do help the patient and raise her powers of resistance. Irrigation of the uterine cavity has from time immemorial been carried out by antiseptic douches, a procedure fraught with more danger than assistance to the patient. Of late years irrigation of the uterine cavity with sterile glycerin has been used for these patients, and in many cases undoubtedly has borne good results. It requires to be done with care lest a fresh supply of organisms is carried into the uterine cavity during the manipulation.

STAPHYLOCOCCAL INFECTION

(DR. P. N. PANTON)

UNTIL about four years ago, and during the previous decade, staphylococcal infections had ceased to excite particular interest, and some of the known facts concerning them were beginning to be lost sight of. Staphylococci are said to produce an intracellular toxin, as distinct from an extracellular toxin such as that produced by the diphtheria bacillus; but the hæmolytic and leucocidal actions of the staphylococcal toxin have been recognised for many years. Four years ago the Bundaberg catastrophe occurred, in which, owing to contamination of a diphtheria toxin-antitoxin mixture with staphylococci, a number of children lost their lives after inoculation against diphtheria; at the time it was thought to be remarkable that staphylococci should be so lethal.

Staphylococci may be, and often are, carried on the skin of people who show no symptoms themselves, but it is doubtful whether virulent strains are ever carried in this way. The carrier may be responsible for outbreaks of infection in others.

In one case the carrier was a nursemaid who had been suffering from styes. She entered a family where there were two children, one of whom shortly afterwards developed a stye and the other a skin abscess. The maid went away for several months and the children recovered; but when she returned, although she was entirely free from symptoms, there was a fresh outbreak of infection in the children. The conjunctival sac of the nursemaid was found to give cultures of a fairly virulent strain of *Staphylococcus aureus.*

Where children develop staphylococcal infections it is always worth while looking round the household for a carrier.

Once an infection has been incurred, subsequent attacks are common. A carbuncle may be followed by an outbreak of boils in the same patient which may persist for months. Animal experiments throw some light on this susceptibility to fresh infection. An area of a rabbit's skin is shaved and a dose of staphylococcal culture, sufficient to produce a spreading lesion, is injected intradermally. At the same time one-tenth of the dose is injected a short distance away, and one-hundredth and one-thousandth of the dose at other neighbouring sites. One-tenth of the dose will probably produce a small lesion, and one-hundredth and one-thousandth none at all. If the lesions are allowed to heal and the whole process is gone through again several times there comes an occasion, after the third or fourth repetition, when the original dose will produce only a small lesion; one-tenth of the dose will also produce a small lesion, but one-hundredth and one-thousandth of the dose, instead of producing no lesions at all, now give rise to lesions similar to that produced by the full dose. In short, the animal has become partially immunised to the infection, but it has also become susceptible to a much smaller dose. This hypersensitive state is the basis of all recurrent staphylococcal infections. We know of no means to break it—the patient often remains hypersensitive for years. Unfortunately, we can induce it, for example, by overtreatment with vaccines.

If staphylococci are grown on an agar slope for 24 to 48 hours in a partial atmosphere of carbon dioxide, and if the culture, after grinding up the agar, is then filtered, the filtrate is found to be toxic. A fraction of 1 c.cm. injected into the ear-vein of a rabbit causes death almost instantaneously. The toxins which have been isolated have four actions, being lethal, necrosing, hæmolytic, and leucocidal. The lethal toxin is the one responsible for the death of a rabbit when injected in the way described; probably it does not play much part in human pathology. The necrosing toxin has a local action on the skin, and doubtless takes part in the production of local lesions in the human subject. The hæmolysin of staphylococci differs from that produced by hæmolytic streptococci in that it has a very slight effect on human red cells, and only causes lysis of the red cells of certain animals. It is doubtful whether it plays any part in human pathology, but as its content varies with that of the necrosing toxin, and is more easily estimated, it is useful as a measure of the amount of necrosing toxin present. Leucocidin attacks only the phagocytes, throwing them into clumps which are visible to the naked eye. Such tangled masses of phagocytes are probably responsible for pyæmic emboli.

Different strains of staphylococci produce these toxins in varying proportions. Very generally speaking virulent pyæmic cases and cases of carbuncle with spreading infection are due to strains which produce a high content of leucocidin and a low content of hæmolysin. Boils arise from strains with high leucocidin and high hæmolysin, and sycosis from strains with low leucocidin and high hæmolysin. A fourth group of non-pathogenic strains which are largely saprophytic have low leucocidin and low hæmolysin.

This variation in the proportion of the different toxins has a considerable bearing on specific therapy. An autogenous vaccine will have little effect if it is made from a strain with low leucocidin and hæmolysin, whereas a stock vaccine made from a strain with high leucocidin and hæmolysin may work wonders. When a stock vaccine is used it is therefore important to find out what strain of staphylococcus was employed in its preparation. Another method of treatment which deserves trial is immunisation with toxoid. If a small dose of staphylococcal toxin is injected intradermally a wheal will nearly always appear if the patient is adult; children and some young adults may give a negative result, and so will a patient moribund from pyæmia. In other words, sensitive patients react, whereas insensitive or

POINTS IN THE PRACTICE OF GYNÆCOLOGY AND OBSTETRICS

(MR. W. GILLIATT)

IRREGULAR HÆMORRHAGE

It is important to discover the cause of any irregular hæmorrhage at or about the age of 40. Abdominal and vaginal examination should always be carried out in such cases, and in making a pelvic examination it is useful to place the index-finger in the vagina and the middle finger in the rectum. Doubtful cases should be examined under an anæsthetic, and curettage is often of value in establishing the diagnosis. At 40, pregnancy is not excluded, but is rare; myoma is a common cause of irregular bleeding, but other innocent tumours which may cause this symptom are adenomatous polyps and adenomyomata. Infective causes are chronic endometritis and chronic metritis, but in chronic metritis the loss is not as a rule irregular. A malignant tumour may be responsible, such as carcinoma of the uterine body, the cervix, tube or ovary, or, rarely, of the vagina or vulva. In a large number of cases no causal factor will be found; but not until other causes have been excluded by examination is it justifiable to call the condition menopausal.

The diagnosis of *pregnancy* can now be established early by means of the Aschheim-Zondek test. During pregnancy an anterior pituitary hormone is secreted in the urine; urine containing this hormone produces signs of œstrus when injected into immature female mice, and the test is positive within 14 days of the first missed period. The test is especially useful where pregnancy is complicated by fibroids or where ectopic gestation has occurred.

Carcinoma of the cervix is one of the most fatal conditions in gynæcology, the average duration of life in untreated patients being 20 months. Hypertrophic and ulcerative forms are recognised, and the hypertrophic form may be of the cauliflower or, more rarely, of the mushroom type. The diagnosis of both forms can be made on the friability of the tumour, parts of which break away beneath the examining finger. The condition has to be distinguished from erosion, chancre, ulcer due to a pessary, and ectropion. In doubtful cases an anæsthetic should be given, a portion resected, and microscopical examination carried out. Carcinoma of the cervix is rare in nulliparæ, and has been called the price of child-bearing; it is also more common among women of the poorer classes than among the well-to-do, possibly because women in poor circumstances have less time to spare for the investigation of discharges and because, perhaps, they pay less attention to cleanliness. The condition is commonest at the age of 42, but cases have been recorded at all ages from 22 onwards.

Treatment is either by operation, which is only suitable in early cases, or by radium, which is suitable for all cases. Wertheim's operation, as performed in this country, gives a survival rate of 40 per cent. after five years, but it is a severe operation, and has an operative mortality of 8 to 15 per cent. Radium has not been used on any fixed plan in this country, but workers in Stockholm have found that treatment with radium gives a survival rate of 38 per cent. after five years; any type of carcinoma of the cervix can be treated in this way and it is not a severe undertaking. There is a small operative mortality—perhaps 5 per cent.—due to the occasional development of pelvic peritonitis or to a reaction so marked that further treatment becomes impossible. The results of radium treatment of carcinoma of the body of the uterus are discouraging, but fortunately the results of operation in this condition are good. Radium can also be used to induce an artificial menopause, for example, in chronic metritis.

PUERPERAL SEPSIS

Puerperal sepsis may arise either by endogenous or exogenous infection, but it is a good rule never to blame the patient as the source of infection when one can blame one's self. *Exogenous infection* is commoner, more important, and more deadly than autogenous infection. Puerperal sepsis may arise by transfer of infection from patient to patient, but this is almost a thing of the past. It may have its origin in organisms from the throat or nose of the attendants, and for this reason masks ought to be worn as a routine measure throughout the confinement. The incidence of sepsis also depends to a large extent upon internal manipulations and the duration of labour; prolonged labour exhausts the patient and consequently lowers her resistance by diminishing the bactericidal power of the blood. Lacerations also favour sepsis, and 40 per cent. of cases in which manual removal of the placenta is performed show a rise of temperature afterwards. Induction of labour probably encourages infection more than is imagined, and patients with toxæmia are more liable to develop sepsis than others. Exploration of the uterus in a woman showing slight signs of infection should never be carried out unless there is hæmorrhage, and then only with the gloved finger. If the patient has a raised temperature and an offensive discharge exploration is definitely dangerous. Hæmorrhage in labour is another predisposing cause. It is a condition that practitioners are often called upon to treat, and blood transfusion is one of the most valuable methods of restoring the strength of the patient and enabling her to resist infection.

Autogenous infection may occur in the following ways. Hæmolytic streptococci have been found in the vagina in 2 to 3 per cent., non-hæmolytic in 1 to 2 per cent., and anaerobic streptococci in 1 per cent. of normal healthy pregnant women, who do not necessarily develop sepsis. These organisms get into the vagina possibly in old cases of gonococcal infection, in previous cervical tears associated with cervicitis, and as a result of sexual intercourse late in pregnancy. *B. coli* may invade the pelvic organs from the intestinal or urinary tract. And again, lowered resistance may allow organisms in other places to develop increased virulence, and passing through the blood stream reach the uterine cavity—e.g., severe oral sepsis.

The following remarks refer to cases of puerperal septicæmia only.

Organisms.—In addition to the streptococci mentioned above, puerperal septicæmia may be due to *B. coli* and *Staphylococcus aureus.* The most common of these is the hæmolytic streptococcus and, in addition, it is the most deadly. The staphylococcus is the rarest, but fatal cases have been recorded.

Prognosis.—The only sure guide to the severity of the condition and the patient's chances is the pulse-rate. The mortality increases the higher the rate. Under 100 the outlook is not severe, between 110 and 120 the mortality has been suggested as being 20 per cent., with the pulse-rate 140 the mortality is nearly 50 per cent., and over 150 it is 75 per cent. No other condition—such as the temperature, the number of rigors, the state of the lochial discharge—is in any way as reliable as the pulse-rate in foretelling the progress of the disease.

be supposed to have been 161 deaths in each quarter of the year. Why did the deaths go up to 298, nearly double, among those who had left the service, immediately after they left it? Half the deaths of seamen (active service) were until 1929 due to injuries; from these the retired are free, yet 625 of them died in the year after they left the service; but only 642 of the 127,518 men who remained! Can this mean anything else than that many of those shown on their death certificates as seamen "retired"—death certificates required within a year of their leaving the sea—had left the service through illness; had in fact left the service only to die. Unfortunately we are not told from what diseases these 298 in three months, or 625 in a year, did die. What else but phthisis will explain the great mortality at the younger ages, for of the 298 who died within three months of sea service, 208, more than two-thirds, were under 55. In the last five years the death-rate from phthisis was 0·13 in the Army, 0·18 in the Navy, and rather over 0·18 in the merchant service, but we must not forget there are 280 other deaths from respiratory tuberculosis among the retired merchant seamen unexplained. An appendix to this blue-book showing the causes of the deaths of the 298 men who died within three months of sea service, indeed of all men who died within the year, would illuminate our knowledge of the diseases of the seaman. Until this has been seen, or some better information provided, it will always be felt that the tale of damage to health by service at sea is but incompletely covered by the Return of deaths in the active service among the "occupied seamen," annually published by the Board of Trade.

To me it has always been a puzzle why the deaths in the merchant service, with its lamentable want of sanitation, were so few, compared with those in the Navy, where were so many more advantages, but that is now explained in this Report; not ostentatiously, but the evidence can be found. Here, for the first time ever, we can extract a statement of the deaths occurring during a year among the retired seamen, and are also told something of how long after retirement it is they die. We know the "retired" are older than the "occupied," so we are not surprised about the deaths under heart troubles or cancer; but finding so very many phthisical cases does make one doubt whether they were not picked up in the men's sea time, though the deaths came later. In this report for the first time we learn of the prevalence of phthisis among retired seamen, though this striking fact is not considered when the high mortality from heart disease and cancer is being discussed (p. 42). I believe that the deaths from phthisis are so numerous among the retired, because men leave the merchant service to die of phthisis, and this suspicion is upheld by Table 17 in the Report which shows "Shore Deaths (British) by Age and Length of time since last Sea-Service." It accounts for 2524 deaths, concerning 2022 of which it was known how long after their last sea service they had died, and their ages. Here it appears that of the 2022, 298 (14·8 per cent., a seventh of them) died within three months of their last sea service, and these 298 with 161, making 459 (22·7 per cent., nearly a quarter of the whole) died within six months of their leaving the sea. Can anyone but believe that a considerable number of these 298 + 161 left their ships unwell, and in fact left the sea to die. Of these cases dying early, many had not exactly meant to retire, but dying when not on ships' articles, were described as "seamen, retired." In this table there are 12 who died under 20; they all died within the year. Aged between 20 and 25, 57 died, 39, two-thirds of them, within the year. It is a tremendous pity that, when all the death certificates were available, we were not told of the diseases which killed the 625 (31 per cent.) who died within a year of leaving the sea.

MEDICINE AND THE LAW

Fortune-tellers Fined

Two women were fined 40*s.* each for fortune-telling last week at the Marylebone Police-court, both of them pleading guilty. According to the information given by the police to the magistrate, there was an element of faith-healing in the case. One defendant, a French teacher and interpreter aged 42, was stated to have given "readings" at 5*s.* each, which were well attended. Among those who went to these "readings" was a man who had a son, aged 6½ years, suffering from a tuberculous foot. The man's wife complained to the police that her husband was so deeply impressed with the French teacher's healing powers that he took the boy to her to be cured instead of taking him to a specialist. The police visited this defendant and presumably warned her that her fortune-telling practice was illegal. She thereupon obtained the services of the second defendant, a masseuse, aged 54, to tell fortunes. Evidence was obtained against both defendants and they were arrested with the result already stated. They were charged under Section 4 of the Vagrancy Act of 1824, "an Act for the punishment of idle and disorderly persons and rogues and vagabonds in that part of Great Britain called England." The Act covers a wide range of offences. Section 4 imposes a penalty on "every person pretending or professing to tell fortunes or using any subtle craft, means or device by palmistry or otherwise to deceive and impose upon His Majesty's subjects." The words "palmistry or otherwise" have been construed as implying that the subtle craft must either be palmistry or something of the same kind. Thus a mere conjuring trick is outside the section. It has also been held that the words "or otherwise" are distinct from the previous general words and that they will cover such practices as pretending to hold communication with the spirits of the dead. They may, it seems, include anything of an occult or supernatural character. The magistrate, of course, sentenced the defendants for fortune-telling, not for pretending to heal the child; indeed, there is no evidence that the defendants undertook to cure a tuberculous foot. It is no very serious crime to satisfy the demand of credulous folk who will pay their shillings for the thrill of being told the future. If credulity goes so far as to substitute a fortune-teller's magic for ordinary medical treatment, one need not wonder at the vogue of the unqualified practitioner.

A Coroner's Powers

A legal contemporary comments on the reported decision of the Reading borough coroner to exclude solicitors in future from some of their accustomed activities in his court. He intends to take his depositions and to recall the witness, if necessary, for examination. He protests that he does not desire solicitors to come to his court and waste his time, "still less to throw their weight about." With all due respect to insurance companies, he adds, a coroner is not paid to hold inquiries for their benefit.

The coroner's ancient office gives him wide powers.

moribund patients do not. But by adding formalin, or heating the toxin it is possible to make it much less toxic though its immunising properties remain satisfactory. I have tried using toxoid in a few cases of sycosis; the results were not dramatic, but there was considerable improvement in the condition.

Another method of treatment is passive immunisation with antiserum. Until recently no antiserum, made in the light of modern knowledge, was available, but Dr. G. F. Petrie of the Lister Institute, has prepared for us an antiserum by injecting a horse with toxin having a high content of hæmolysin and leucocidin obtained from a strain of staphylococcus causing boils. Again there have been no dramatic results, but in some cases the use of the antiserum seemed to be followed by rapid separation of the slough, healing, and the subsidence of toxic symptoms in cases of carbuncle. In other cases there appears to have been little result; but carbuncles vary so much in the course they take that it is difficult to speak with certainty of the effects of the serum. Some pyæmic cases benefited; some, in which there had been spread of pyæmic abscesses before injection, developed no more abscesses after serum treatment had been begun. In any case, antiserum is the only specific remedy we have at the present time and therefore deserves trial in severe infections. It should be given in 40 c.cm. doses three or four times during the first four days. No further doses should be given after ten days.

Antivirus does not give striking results in my experience. I will not discuss the value of metals such as manganese, since they do not come under the heading of specific therapy. It is important to remember that staphylococcal infections are cut off by a zone of inflammation from the deeper layers of the skin, and if staphylococci are introduced into these deeper layers the patient may die. When incising a boil please be content with an opening that you consider too small rather than run the risk of spreading infection into the deeper tissues. To incise a carbuncle unless to evacuate pus is unjustifiable.

MORTALITY IN THE MERCANTILE MARINE

By Fleet-Surgeon W. E. Home, O.B.E.

Everyone interested in the health of the British seamen of the mercantile marine will be very grateful to the Board of Trade for initiating the investigation and publishing the statistics which now see the light in this blue-book.[1] In 1924 the Royal Sanitary Institute memorialised the authorities on the need for the issue of an official death-rate for British merchant seamen, as it was felt that the sanitary defects under which merchant seamen suffered in their ships must make their effects visible in the death-rate, increasing deaths in certain directions, and so helping to make improvements more obviously necessary. The Institute wanted a death-rate found yearly for seamen, being convinced that the insanitary conditions they knew of on ships could not but write their mark on any true death-rate; and, given such, the need of improvements would come clearly to notice, when something more would be done than seemed likely so long as there was no accurate knowledge to force it on. They wanted a death-rate for "occupied" seamen, the men on ships, the men with whom the port sanitary authorities were concerned, the men whose deaths were reported in the annual return of the Board of Trade, the men suffering from the sanitary defects of the ships. But when the committee which the Board appointed to examine this question reported, they were found to have decided that a death-rate for "occupied" only was impracticable of attainment, and recommended the search for a death-rate for the "occupied and retired." At that time the securing of this information seemed more visionary than the original objective. The deaths of "occupied" were known, the number at risk on certain census days was also known, and was roughly estimated for the year by the Board of Trade, but as for the "retired" or unoccupied seamen, whose deaths were only known to the local registrars, there was no faintest idea of the total number of their deaths, still less of the total at risk. How could a death-rate be got at?

Now comes along this blue-book, with a careful record and analysis of the facts, and the whole matter is most lucidly cleared up. Thus definitions are given of "seamen," as understood by the Registrar-General in the general Census, and by the Registrar-General of Shipping and Seamen in the Census of Seamen; the difficulty of estimating a total of seamen for any year is discussed, and the extreme uncertainty of securing complete and accurate lists of deaths and numbers of "retired" seamen is explained. Ultimately the deaths of each class in the examination year (ending Sept. 30th, 1929; what a pity not a calendar year!) were collected. They were 642 among the 127,518 "occupied" seamen, and 2524 among a body of "retired" seamen, whose number cannot be stated until the complete figures of the general Census of 1931 are available.

The "occupied" and "retired" of seamen have to one another a relation quite different from that existing in other trades. Generally the "occupied" go on together, as in a river like Niagara, quite smoothly until the break comes, when they plunge into the "retired" pool, whence is no return. But the service of seamen is not continuous, they sign on for a ship and are "occupied," they sign off and cease to be "occupied," returning again to that class when they sign on for another ship. Imagine a terra-cotta water cooler, with a saucer below. Water oozes through its sides, some is evaporated (deaths), some drops into the saucer below (men signing off), and is again returned to the cooler (men signing on for a new ship). The water in the cooler represents the "occupied seamen"; some of them die and do not return, but many come back and with recruits keep up the total of the industry. The important point is that the number unemployed on any day is unknown, their health conditions are unknown, and these indeed often come only to notice when the men die, and are then registered as "retired." Now nothing was known about these deaths until this blue-book appeared, in which is mentioned that in the examination year 2524 deaths of "retired" seamen occurred, of 2022 of whom the time since their last sea service is stated; and 298 died within three months of leaving the sea, a great mortality just when they left. Surely these deaths were due to the active service. For as there were 642 deaths in the active service in the year, there may reasonably be supposed to have been 161 deaths in each quarter of the year. Why did the deaths go up to 298, nearly double, among those who had left the service, immediately after they left it? Half the deaths of seamen (active service) were until 1929 due to injuries; from these the retired are free, yet 625 of them died in the year after they left the service; but only 642 of the 127,518 men who remained! Can this mean anything else than that many of those shown on their death certificates as seamen "retired"—death certificates required within a year of their leaving the sea—had left the service through illness; had in fact left the service only to die. Unfortunately we are not told from what diseases these 298 in three months, or 625 in a year, did die. What else but phthisis will explain the great mortality at the younger ages, for of the 298 who died within three months of sea service, 208, more than two-thirds, were under 55. In the last five years the death-rate from phthisis was 0·13 in the Army, 0·18 in the Navy, and rather over 0·18 in the merchant service, but we must not forget there are 280 other deaths from respiratory tuberculosis among the retired merchant seamen unexplained. An appendix to this blue-book showing the causes of the deaths of the 298 men who died within three months of sea service, indeed of all men who died within the year, would illuminate our knowledge of the diseases of the seaman. Until this has been seen, or some better information provided, it will always be felt that the tale of damage to health by service at sea is but incompletely covered by the Return of deaths in the active service among the "occupied seamen," annually published by the Board of Trade.

Fortune-tellers Fined

Two women were fined 40*s.* each for fortune-telling last week at the Marylebone Police-court, both of them pleading guilty. According to the information given by the police to the magistrate, there was an element of faith-healing in the case. One defendant, a French teacher and interpreter aged 42, was stated to have given "readings" at 5*s.* each, which were well attended. Among those who went to these "readings" was a man who had a son, aged 6½ years, suffering from a tuberculous foot. The man's wife complained to the police that her husband was so deeply impressed with the French teacher's healing powers that he took the boy to her to be cured instead of taking him to a specialist. The police visited this defendant and presumably warned her that her fortune-telling practice was illegal. She thereupon obtained the services of the second defendant, a masseuse, aged 54, to tell fortunes. Evidence was obtained against both defendants and they were arrested with the result already stated. They were charged under Section 4 of the Vagrancy Act of 1824, "an Act for the punishment of idle and disorderly persons and rogues and vagabonds in that part of Great Britain called England." The Act covers a wide range of offences. Section 4 imposes a penalty on "every person pretending or professing to tell fortunes or using any subtle craft, means or device by palmistry or otherwise to deceive and impose upon His Majesty's subjects." The words "palmistry or otherwise" have been construed as implying that the subtle craft must either be palmistry or something of the same kind. Thus a mere conjuring trick is outside the section. It has also been held that the words "or otherwise" are distinct from the previous general words and that they will cover such practices as pretending to hold communication with the spirits of the dead. They may, it seems, include anything of an occult or supernatural character. The magistrate, of course, sentenced the defendants for fortune-telling, not for pretending to heal the child; indeed, there is no evidence that the defendants undertook to cure a tuberculous foot. It is no very serious crime to satisfy the demand of credulous folk who will pay their shillings for the thrill of being told the future. If credulity goes so far as to substitute a fortune-teller's magic for ordinary medical treatment, one need not wonder at the vogue of the unqualified practitioner.

A Coroner's Powers

A legal contemporary comments on the reported decision of the Reading borough coroner to exclude solicitors in future from some of their accustomed activities in his court. He intends to take his depositions and to recall the witness, if necessary, for examination. He protests that he does not desire solicitors to come to his court and waste his time, "still less to throw their weight about." With all due respect to insurance companies, he adds, a coroner is not paid to hold inquiries for their benefit.

The coroner's ancient office gives him wide powers.

Unlike a High Court judge, he does not sit as an umpire to see fair play while plaintiff and defendant or prosecution and defence present their respective cases. There are no parties to the proceedings at an inquest: no preliminary pleadings have narrowed the issue. The inquisition may end in the commitment of somebody to stand his trial in a criminal court; it does not begin, like a prosecution at the assizes, with the indictment of a named person upon a definite charge. Historical origins have developed the coroner as an examining magistrate. He gathers and sifts the statements and suspicions of the neighbourhood. He is unfettered by the strict rules of evidence, for he scarcely knows what may or may not be relevant. He examines the witnesses himself but in common fairness, where the evidence affects particular persons, he will allow them or their representatives to ask their questions too. In spite of a recent instance to the contrary, he usually permits neither counsel nor solicitor to address the jury. It is said, on the authority of Garnett v. Ferrand, that he has a discretion to exclude barristers and solicitors from his court or at any rate to prevent their examining or cross-examining a witness. Be that as it may, the conduct of the whole investigation is in his own hands; he is largely a law unto himself; and thus those who have wide experience of attending inquests in many towns and counties sometimes report singular diversities of local practice. It would be a pity if those divergencies should become too conspicuous. Coroners should be able to control the proceedings in their courts without recourse to a general muzzling order.

The Severity of Coroners' Juries

Mr. Justice MacKinnon, charging a grand jury recently at Gloucester, contrasted the attitude of juries in coroners' courts and at assizes. It was, he said, a matter of wonder to him that coroners' juries seemed only too eager to find verdicts of manslaughter against motorists, whereas assize juries were unduly reluctant to convict a motorist on such a charge. He was inclined to ascribe this difference of attitude to the fact that the former class of jurors is conscious that the coroner has no power to award punishment without further trial, whereas at assizes a jury has a feeling of responsibility inasmuch as punishment must follow a verdict of guilty. The case which elicited these observations was one in which an advertising agent had left his motor-car at the side of the road while he went into a shop. There was a slope in the road, the brakes gave way, the car ran down a hill and killed a boy. The coroner's jury found a verdict of manslaughter and in consequence—without, apparently, any commitment by magistrates—the motorist's name appeared in the calendar of persons for trial at Gloucester assize. Taking the judge's hint perhaps that the coroner's jury had taken the case too seriously, the grand jury threw out the bill against the motorist who thus had not to stand his trial after all.

(FROM OUR OWN CORRESPONDENT)

PROPOSED REDUCTION OF SALARIES

The Cork county council recently invited its several whole-time officials, lay and medical, to consent to a deduction of 10 per cent. from their salaries. The enforced reduction in the salaries of civil servants carried out some months ago has, no doubt, encouraged local authorities to treat their officials with an equal lack of consideration. The salaries of the whole-time medical officers of the County Cork are already as low as can reasonably be expected, and there is no reason why they, more than any other class of the community, should be called on out of their own pockets to contribute to the relief of the rates. There is little doubt that if the whole-time medical officers were to fall into the trap set for them the next attack would be made on the salaries of the part-time medical officers, and the whole fruit of the struggle of the last 30 years for adequate remuneration would be imperilled. Reduction of salaries cannot at the moment be carried out except by consent.

(FROM OUR OWN CORRESPONDENT)

NEGLECT OF NOTIFICATION OF INFECTIOUS DISEASES

The legislative machinery for the notification of infectious diseases in France exists right enough. But its wheels do not always turn. There is article 15 of the law of Nov. 30th, 1892. There is also article 5 of the law of Feb. 15th, 1902. This legislation deals with the conflicting interests of respect for professional secrecy and respect for public health. But such rules are apt to receive cavalier treatment at the hands of the practitioner who is careless and forgetful, or who thinks in terms of the individual (his present patient) rather than in terms of the community (potential patients who may suffer from his neglect to notify). Matters came to a head a short time ago with a formal complaint to the Academy of Medicine by Dr. A. Loir and Dr. Daniel, of le Havre. They stated that for some time past medical practitioners have been sheltering behind professional secrecy in order to avoid notifying their cases of infectious diseases. They added that throughout France certain doctors, and even groups of doctors, betray the same deplorable tendency. Now the Academy of Medicine is a useful forum for complainants for this reason, among others, that its transactions have the ear of an important public. What is said at the Academy of Medicine to-day filters quickly out into the streets, if not to-morrow, then not many days later. And the daily illustrated paper *Excelsior*, whose profusion of pictures and paucity of words have endeared it to a vast public, has taken up the hue and cry in an interview one of its staff has had with Justin Godart, Minister of Public Health. In this interview he draws attention to a point which the defaulting medical practitioner may have overlooked, and which should prove a spur to conscientious notification. It is this, that while the fine for failing to notify a case of infectious disease may be only 5 francs, the payment of this modest sum does not necessarily mean that the matter ends there. For if failure to notify a case of infectious disease is followed by its spread to some other person or persons who bring an action for negligence against the practitioner concerned, the afore-mentioned fine may prove a stepping-stone to damages of a very different value.

TWO CONGRESSES

The forty-first Congress of French Surgery, which took place in Paris early in October, gave its president, Prof. Pierre Duval, an opportunity to voice his views on the educational system which turns out French surgeons. Besides such standard subjects as physiology and anatomy, he would like the future surgeon to have more than a nodding acquaintance with other subjects. He should, for example, take part in the laboratory work of experimental medicine. The evolution which Prof. Duval would like to see hastened is that from the merely dexterous handicraftsman to the scientist who has taken a doctor's degree in surgery. The subjects on which attention was focused at this congress were the surgery of the heart and neighbouring structures, the surgical treatment of the diseases of the blood—a subject whose very title might have been given a Gilbertian interpretation only a few years ago—and the surgical treatment of chronic, non-tuberculous diseases of the hip.

In his opening address to the twenty-second Congress of French Medicine, Prof. Fernand Bezançon tried to extract some main guiding lines out of the tangle of modern polypharmacy. It is not only that an infinite variety of remedies is now available for one and the same disease; an infinite variety of diseases is treated by one and the same remedy. Protein-shock therapy is dispensed round-handedly to sufferers from boils, urticaria, asthma, and so on; gold is administered to patients with another wide range of diseases, and specificity in treatment has become a confused conception in some quarters. The employment of one and the same drug in a host of different diseases may, however, be defended if proof can be found of the existence of certain features common to all these apparently different ailments. It is probably to interpret Prof. Bezançon truthfully, to credit him with a greater belief in the future of the remedy which acts on the patient's tissues than in that which is supposed to have some specific action on invading cells.

FIRST-AID ON THE HIGHWAYS

During the recent meeting of the board of governors of the League of Red Cross Societies, which brought to Paris Red Cross representatives of 58 different countries, a demonstration was given of air ambulances and first-aid stations on the highways. After visiting Le Bourget airport and inspecting a passenger aeroplane capable of conversion into an air ambulance on short notice, the Red Cross delegates were taken on the Senlis road, where they inspected some of the 2000 first-aid posts which have been established along approximately 8000 kilometres of roads in France by the Union Nationale des Associations de Tourisme, in conjunction with the French Red Cross. Dr. Béhague, president of the Association's committee on first-aid on the roads, gave an account of the functioning of the system which is now working with such marked success in France.

PANEL AND CONTRACT PRACTICE

Omission to Disclose

AT the twenty-ninth conference of the National Association of Insurance Committees, which met recently at Buxton, the president, a Lancashire man, made the significant declaration :—

> "It is admitted on all hands that the insurance medical service has justified itself and that it is incomparably better than any previous service available to the same class of person. It is a lasting tribute to all parties, to the committees, the doctors, and the chemists, who are working together in hearty and harmonious coöperation, that such sound progress has been made."

Some of the resolutions before the conference were of the hardy annual type. The Croydon representative contended once again that complete freedom to change his doctor should be given to insured persons, refusing to admit that frequent change may be due to pique and leads to excessive certification. A London delegate said he could prove from figures in his office that the restrictions on change had reduced the number of claims and the suggestion of free choice was lost. On the other hand an amendment was carried to substitute three months for one month in Clause 7, III., of the first schedule of the Medical Benefit Consolidated Regulations, 1928. This clause deals with the patient who obtains treatment privately from a doctor without declaring the fact that he is an insured person. At the present time he can make a claim either for a refund of the fee paid or for a withdrawal of the doctor's account, but he must claim within a month. A large number of these claims have to be disallowed on the ground that they are "out of time" The doctor is not likely to welcome this suggestion because anything which tends to delay such claims will make it more difficult to decide the facts. A certain number of insured persons claim private treatment and deliberately omit to disclose to the insurance practitioner (not necessarily their own) that they are insured persons. They do this thinking they will obtain better treatment, no waiting about at chemists for medicine. The doctor's medicine is always thought to be better than the chemist's. When treatment is safely over they claim from the insurance committee a refund under the clause. Committees generally act fairly in these cases; they allow or disallow according to the merits of the case, and they rarely inflict a fine although they have the power to do so. The clause gives much trouble in the way of correspondence with committees, looking up records, claims to be sent in for medicine supplied, arguments as to how the doctor was to know or not to know the person was insured, and so on; but it does prevent the doctor coming before the medical service subcommittee on a charge of receiving fees improperly.

A Question of Personal Service

The London Insurance Committee spent much time this week discussing the question of an assistantship and personal service. In this case the practitioner who has a smallish panel in the north of London bought the practice of a retiring practitioner south of the river with a large panel. He went himself to live on the south side, placing an assistant in residence on the north where he arranged himself to visit and attend patients at least four times a week, and more frequently if asked for. The insurance committee refused permission to employ an assistant. The panel committee, after hearing the practitioner, decided that he should be allowed to employ an assistant. The Ministry will presumably be asked to decide. One argument used was that all the insured persons in the northern practice had selected this doctor so that they might have his personal service; to put in an assistant to attend them was not fair to them. The position really is this. A principal is bound by regulations to do his work himself unless prevented by absence from home, illness, or other reasonable cause, when he must provide a deputy; assistants are entitled to deputise for a principal. An insured person therefore cannot protest at being attended in the first instance by the assistant, but he can (if he is so disposed) demand that in future he shall be attended by the principal, and he is, of course, entitled to continuity of *treatment*.

CORRESPONDENCE

CHLOROFORM CAPSULES IN CHILDBIRTH

To the Editor of THE LANCET

SIR,—In your issue of July 30th mention was made of the fact that a supply of chloroform capsules, as described by Mr. L. C. Rivett, F.R.C.S., in his paper read before the Royal Society of Medicine on June 17th, could be obtained free of charge for experimental purposes by all hospitals for a period of three months upon application to the secretary, National Birthday Trust Fund, Empire House, 175, Piccadilly, London, W.1. I am glad to say that 73 hospitals have availed themselves of the offer, and tests are accordingly being made on a wide scale. The results so far reported have been uniformly satisfactory.

It is now desired by the National Birthday Trust Fund to extend the offer to all medical practitioners for a further two months. Two boxes of 12 capsules will be supplied free to any registered medical practitioner for experimental use in return for full reports, forms for which will be enclosed; and a further supply can be obtained at cost price or free, if required for use in genuinely necessitous cases. It is especially hoped that medical officers of health will make a trial of these capsules.

It is also desired to make clear that within the three months period from the first application, repeat orders from those hospitals which have already received a supply are welcomed. Although the majority of hospitals have applied for considerable quantities and have repeated their orders, a certain number have asked for only one box, scarcely a sufficient quantity for an adequate test.

As already pointed out in your columns the reports, when received, will be submitted for examination and report to a medical committee of which Dr. J. S. Fairbairn, President of the College of Obstetricians and Gynæcologists, is Chairman.

I am, Sir, yours faithfully,

JULIEN CAHN,
Chairman, National Birthday Trust Fund.

Empire House, 175, Piccadilly, W., Oct. 31st, 1932.

SAFE MILK

To the Editor of THE LANCET

SIR,—During the past few weeks letters have appeared in your columns which indicate that doubt still exists as to the safety of Grade A (T.T.) milk, particularly as regards the freedom of this grade of milk from tuberculous infection.

So far as Scottish conditions are concerned, figures are available which show conclusively that raw milk from licensed tuberculin-tested herds is remarkably free from such infection. Three years ago, in a survey of the results of routine tests carried out in three large Scottish cities,[1] I pointed out that while milk from ordinary herds showed a fairly high incidence of infection, an examination of 550 samples of milk from tuberculin-tested herds supplied to Glasgow hospitals failed to reveal a single positive sample. Some doubt existed, however, as to the reliability of the routine test employed in examining these samples, and it appeared desirable that a further comprehensive investigation should be made, using a far more stringent technique. During the past two years such an investigation has been carried out at the Hannah Dairy Research Institute, the milk samples being tested by inoculation into duplicate guinea-pigs, the subsequent post-mortem examination being carried out after a four-week and an eight-week period respectively. Samples of milk were obtained direct from practically every licensed tuberculin-tested herd in Scotland and, in addition, a large number of retailed bottles of Certified and of Grade A (T.T.) milk were bought "over the counter" in the four largest Scottish cities. Altogether 750 samples were examined. *Of this number only one sample proved positive*—a result which is in marked contrast with Dr. Gloyne's findings.[2] Moreover, an immediate investigation of the herd from which this single infected sample was obtained revealed the source of the infection. Briefly, a defective fence had allowed the "free" cattle to mix with neighbouring infected stock, and a subsequent tuberculin test on the "free" herd revealed the presence of six newly infected reactors.

The potential danger to the milk-supply of such casual infection in a tuberculin-tested herd is obviously a matter of great importance, and the Hannah Dairy Research Institute has therefore also undertaken an inquiry into the frequency of infection in Scottish licensed herds. The report of this inquiry (issued as Bulletin No. 2 of the Institute) shows that out of 28,221 tuberculin tests made since 1923 only 428 proved positive, indicating the average number of reactors to be about 1·5 per cent. of the cow population of tuberculin-tested herds. Since it is probable that not more than 1 per cent. of such reactors can be assumed to secrete infected milk, it follows that the actual proportion of reactors in licensed herds which might be considered as actively dangerous, works out at 1 per cent. of 1·5 per cent., or 3 in every 20,000 animals. Moreover, it was shown in the same report that over 90 per cent. of the reactors in such herds had contracted infection from easily avoidable sources so that the risk of dangerous infection in an efficiently run herd would appear to be minute.

The above results indicate that, as far as Scottish conditions are concerned, the risk of tuberculous infection in milk from licensed tuberculin-tested herds—as judged either by direct examination of milk samples for living tubercle bacilli, or by inference from the number of reactors in such herds—is in practice negligible. There remains the risk of infection with other milk-borne diseases: septic sore-throat, diphtheria, scarlet fever, and enteric fever. Obviously it is impossible to give an assurance that *any* type of milk, or indeed any foodstuff, will be free from the risks of such infection since these arise from casual contamination rather than from faulty methods of production. At the same time it seems likely that the more careful methods which must be used in the production and handling of Certified and Grade A (T.T.) milk (as judged by the low bacterial count required for these grades) and the more educated mentality of the workers concerned will limit the risk of infection. That this is true may be shown from the following facts. In the first place it appears that no milk-borne infection has ever been traced to Certified or Grade A (T.T.) milk in any of the four largest Scottish cities although, according to the recent report (for the year, 1931) of the medical officer of health for Glasgow, milk-borne infections have been traced relatively, frequently to ordinary raw milk, and in one instance (200 cases of scarlet fever) to a pasteurised milk supply. In the second place, I understand that in the large scale milk-feeding experiment carried out in Lanarkshire schools when 10,000 children were given raw Grade A (T.T.) milk for a period of four months, no cases of milk-borne disease occurred. This fact should give some reassurance to those of your correspondents who have expressed doubt as to the safety of Grade A (T.T.) milk for children of school age.

---

[1] Brit. Med. Jour., 1929, ii., 453.

[2] Tubercle, July and August, 1932.

The whole of the facts stated in this letter apply to Scottish conditions. I do not know how far similar facts hold for English conditions, though Dr. Gloyne's results give some grounds for uneasiness. In this connexion it is possible that the administration of the Milk Designations Order is more efficient in Scotland than in England owing to the fact that while in Scotland it is the rule for each county to have at least one full-time veterinary officer, in England it is the exception. In any event it appears that there is complete justification for the stipulation made in the Education (Scotland) Act, 1930, that free milk supplied to school-children by local education authorities in Scotland should either be "Certified milk, or milk of the next best grade available." The real difficulty, at least so far as the south-west of Scotland is concerned, is the fact that the existing supply of milk from tuberculin-tested herds seriously exceeds the demand. According to the chief veterinary officer for Ayrshire, for instance (report for 1931), only 60 per cent. of the milk of 55 licensed herds in his county reached the market in 1931 as graded milk, the excess of supply over demand averaging about 1600 gallons per day. In addition, he estimates that a further supply of 1200 to 1300 gallons per day could be made available from other tubercle-free herds if the demand were stimulated. In this area alone, therefore, a total of practically 3000 gallons of milk from tubercle-free herds cannot find a market. It is a disaster that progressive milk producers should receive such scant encouragement in their efforts to provide the public with a first-rate product.

In conclusion I desire to emphasise the fact that this letter is not directed against those who advocate the pasteurisation of the bulk of the ordinary milk-supply, a procedure which may well be necessary until the incidence of bovine disease is reduced and the general level of efficiency in the production of milk is raised. My sole object is to show that a very definite safeguard against milk-borne disease is already available in Certified and Grade A (T.T.) milk, that a plentiful supply of the latter could be made available at a reasonable price if the demand were increased (particularly if the Government agreed to give some practical assistance to those desirous of clearing their herds of tuberculosis), and that, so far as any future national policy is concerned, the encouragement of licensed tuberculin-tested herds has the two-fold advantage of providing a safe milk-supply for the public, and of effecting valuable improvement in the health of farm stock.

I am, Sir, yours faithfully,

NORMAN C. WRIGHT.

The Hannah Dairy Research Institute,
Kirkhill, Ayr, Oct. 28th, 1932.

THE POLICY OF SCHOOL-CLOSURE

To the Editor of THE LANCET

SIR,—Once more the anxious question of the advisability of the dispersal of a school when cases of epidemic poliomyelitis appear is raised, and no doubt will continue to be raised until something definite has been settled. This time the Headmaster of Stowe has to bear the brunt of what must have been clear to him as the only course to save the lives and limbs of boys committed to his charge. The meticulous care he took to prevent the spreading of the infection safeguarded the community. Letters appearing in the daily papers make it clear that parents are carrying out his suggestions, and are grateful for getting their boys out of the danger zone.

It is no light matter disbanding a school, and it is only done when there is no other safe course evident to the "men on the spot." From the nature of things, these men are above the average—mediocrities do not get or hold high competitive appointments—and are well-qualified to weigh pros and cons and to decide. The Ministry of Health do not seem to think so, and proceeded to say so by broadcast on Oct. 24th (which was reproduced in the papers of Oct. 25th), obviously—as I shall show—without full knowledge of the facts. To take some of the broadcast points :—

Slight rise :

8 cases during week ending August 20th.
48 cases during week ending Oct. 8th.

A six times increase is not slight.

Singly and widely scattered.

This is wrong. The essence of poliomyelitis is that it appears in two forms, sporadic and epidemic. They are clinically identical but vastly different in effects. The sporadic form does not spread, the epidemic form does and it is deadly. The kindest thing is to assume that this is a clerical error which will be corrected.

Balance of advantage is in favour of keeping highly susceptible persons within the danger zone. How is the balance arrived at ? Let us have the data, please.

Conducted on hygienic lines.

My reply to this is to cite the table given in A. S. MacNalty's "Epidemic Diseases of the Central Nervous System" and Dr. MacNalty's comment on the figures.

TABLE XVI. *Poliomyelitis—Sanitary Conditions*

—	Dirty.	Fair.	Clean.	No data available.
Patient ..	0·9	4·8	53·5	40·8
House.. ..	3·9	14·5	63·6	18·0

These figures relating to the cleanliness of the patient and house approximate closely to similar figures which were obtained for the year 1917—namely, 53·7 and 63·3 per cent. They indicate, as do American statistics, that the disease cannot be regarded as specially associated with uncleanliness of the patient or of the patient's surroundings.

The obvious deduction is that good hygienic surroundings favour poliomyelitis. This was also seen in a spot-map of the Leicester epidemic of 1926. Stoneygate had more cases (proportionally) than Belgrave Gate—the former "west end," the latter a slum.

In the 1926 epidemic Broadstairs schools asked for advice and they were advised to carry on. They did—until parents removed what was left of their children. Other schools, knowing the disastrous results of the carry-on policy, dispersed, with happy results to their school populations. This question of dispersal of schools during epidemics of poliomyelitis is important : it must, and can, be definitely settled by careful investigation of past epidemics. Broadstairs alone affords valuable evidence. Let us have a full report of the Broadstairs epidemic from the Ministry of Health.

The Britisher's innate respect for "authority" makes headmasters loath to disband when they know it is the only safe course. It is not fair to these men to be acting in opposition to "authority." Until the Ministry of Health can say "We have shown you how to detect carriers of poliomyelitis virus and effectively treat the disease," safety first; dispersal is the best policy.

I am, Sir, yours faithfully,
WILLIAM DUNN,
Oct. 29th, 1932. Medical Officer to Uppingham School.

A CHRISTMAS APPEAL

To the Editor of THE LANCET

SIR,—May I ask once again for the kind hospitality of your columns on behalf of the Royal Medical Benevolent Fund? We have for several years past given a Christmas gift to all our annuitants and to the poorest of the grantees; and in order to accomplish this we have been compelled to ask for the assistance of our brethren in the medical profession. This is the special object for which I desire to secure your approval and support.

We hope with the help of our sympathisers to allot 30*s.* each to these poor folks. In these hard times old and infirm doctors, widows and children of deceased doctors, are often hard pressed even for the bare necessities of food, clothing, and fuel. Anything that is given to us for this object will be a real boon.

Donations may be sent to the hon. treasurer, Royal Medical Benevolent Fund, 11, Chandos-street, Cavendish-square, London, W.1.

I am, Sir, yours faithfully,
THOS. BARLOW,
President of the Royal Medical Benevolent Fund.
Nov. 1st, 1932.

PHARMACOPŒIAL LINIMENTS

To the Editor of THE LANCET

SIR,—Amongst the preparations in everyday use in dermatological practice, Linimentum Calaminæ has been proved of great value. The name is unfortunate, as most liniments are more liquid, and are generally understood to be applications that are rubbed on. Lotio Calaminæ Oleosa would indicate its uses more accurately. The formula is to be found in the British Pharmaceutical Codex 1923 as follows:

Prepared calamine	45·7
Zinc oxide	34·3
Solution of lime	500·0
Olive oil to	1000·0

In the pharmacopœias of the general hospitals it varies slightly, with olive, sesame, arachis, or almond oil as the oily constituent.

The consistency of all olive oil preparations changes according to the amount of fatty acids in the oil, and therefore the finest quality of oil will give an inferior preparation, which separates badly. It has been found necessary, therefore, to use either an inferior oil of high acid value or to add a small quantity of oleic acid to make a stable product. The Pharmacy Subcommittee for the revision of the B.P.C. therefore proposes the following formula:

Calamine	45·7
Zinc oxide	34·3
Oleic acid	5·0
Wool fat	10·0
Liquid paraffin	485·0
Solution of calcium hydroxide	500·0

This gives a uniformly good preparation which does not thicken appreciably on keeping and is therapeutically and pharmaceutically sound. It retains all the cooling, evaporating, and soothing properties without the disadvantages above-named. It has been tried clinically through the courtesy of Dr. A. M. H. Gray, at University College Hospital and at the Hospital for Sick Children, Great Ormond-street, for over six months. I am permitted to state that clinically the new preparation is not inferior in any way to the old one and possesses the advantage, both for private and hospital practice, of better keeping properties.

Linimentum Ammoniæ B.P. 1914, after keeping for a short while, has either separated into two layers, or become so thick that it is almost impossible to remove it from the bottle. It has been omitted from the B.P. 1932, and will therefore become a B.P.C. preparation, by arrangement with the Pharmacopœia Commission. Its efficacy depends on the ammonia content and the friction with which it is applied, and not on the oil. The B.P.C. Revision Committee proposes to improve the formula as follows:

Dilute solution of ammonia	250
Oleic acid	25
Liquid paraffin	725

Mix the oleic acid with the liquid paraffin, add the dilute solution of ammonia, and shake.

This preparation does not thicken or separate, and yields a reliable and satisfactory liniment.

Early publicity and criticism of changes in official formulæ are desirable, and it is with this object that I ask the courtesy of your columns.

I am, Sir, yours faithfully,
J. WICLIFFE PECK.
Hospital for Sick Children, Great Ormond-street, W.C.,
Oct. 17th, 1932.

INDICATIONS FOR AND AGAINST CÆSAREAN SECTION

To the Editor of THE LANCET

SIR,—In your report of this discussion (p. 944) an observation I made is incorrectly reported, and my own observation itself is inaccurate. I beg leave to correct the double error. The report should have read that an analysis of the deaths in eclampsia in Great Britain (excluding Ireland) showed that out of 45 maternal deaths, 17 women died undelivered —i.e., 37 per cent.

I am, Sir, yours faithfully,
EVERARD WILLIAMS.
Wimpole-street, W., Oct. 28th, 1932.

TROPICAL ULCER AS A DEFICIENCY DISEASE

To the Editor of THE LANCET

SIR,—In your issue of Oct. 22nd (p. 889) Dr. L. J. A. Loewenthal tells us that the great majority of tropical phagedænic ulcers healed rapidly when daily intravenous injections of calcium chloride were given. Many years ago I published a note[1] on the value of calcium iodide in the treatment of ulcers of the legs, especially those of a chronic nature. At that time I received a number of letters from abroad including some from the tropics in which it was stated that calcium iodide had proved of value in such cases. I drew attention to the fact that these ulcers occurred in people whose food contained too little lime. This point was re-emphasised in my book "The Heart and Spleen in Health and Disease."

I am, Sir, yours faithfully,
G. ARBOUR STEPHENS.
Swansea, Oct. 28th, 1932.

THE ACTIVATION OF INSULIN

To the Editor of THE LANCET

SIR,—I have read Dr. Himsworth's stimulating article in your last issue (p. 935) with great interest and I agree that the best explanation of the relative inefficacy of insulin in some cases is the absence of some insulin activator—called by him insulin-kinase. Studies of an insulin-resistant diabetic some years ago[1] led me to suggest in this case the absence of a necessary "insulin co-enzyme." Dr. Himsworth's suggestion that the liver is at fault in such conditions is interesting, but in my experience not supported by clinical facts, although I have been on the outlook for such a possibility. I shall look forward with great interest to the publication of the experimental facts on which he bases his hypothesis.

I am, Sir, yours faithfully,

Harley-street, W., Oct. 29th, 1932. R. D. LAWRENCE.

CITRATED BLOOD FOR INJECTION

To the Editor of THE LANCET

SIR,—My friend, Dr. R. C. Lightwood, has called attention to the fact that in my paper on Hæmorrhagic Disease of the New-born (THE LANCET, Oct. 22nd, p. 887) I did not give any reason for recommending that blood injected intramuscularly or subcutaneously should be citrated. Theoretically it would seem unwise to alter in any way the chemical composition of blood before injection; but in actual practice there is no evidence that citration of blood lessens its efficacy in controlling hæmorrhage, whilst most workers will admit that this simple precaution against clotting of the blood in syringe and needle ensures that the injection of an adequate volume of blood may be made with ease and without undue haste. I had no other reason for my recommendation.

I am, Sir, yours faithfully,

Liverpool, Oct. 29th, 1932. NORMAN B. CAPON.

CEREBELLAR SYNDROME IN MIGRAINE

To the Editor of THE LANCET

SIR,—The symptoms Dr. William Phillips mentions (last week, p. 941) are somewhat rare, but sufferers from migraine are very diverse and suffer from a multitude of different syndromes—cerebral, ocular, non-ocular, abdominal, &c., and much has been written on the subject. I was, however, surprised that no mention was made of any administration of arsenic or luminal in this case, for the latter especially is excellent in migraine; given if possible before an impending attack, for if given during an attack it is not absorbed, owing to spasm of the pylorus.

I am, Sir, yours faithfully,

Cambridge, Oct. 31st, 1932. H. WESTGARTH TAYLOR.

CORRIGENDUM.—In the letter by Mr. H. M. Woodcock, D.Sc., on Proteolytic Ferment in Amœbic Dysentery (last week, p. 972), the last sentence in the first paragraph should read: In the malarial parasites, for instance, the residual product of digestion, the pigment, is formed only in the cytoplasm of the parasite, never in the more or less used-up red corpuscle.

PUBLIC HEALTH SERVICES

Muddle-headed Economy

ANTICIPATING curtailment of educational activities to be recommended by the Government's Committee on Local Expenditure, a recent issue of *Education* animadverts upon the working of the school medical service, which, it is alleged, could be made equally effective at less than the present cost. The blame for this state of affairs is placed, not upon the local education committees on whom ultimately responsibility must fall, but upon the professional administrators of the service. There are vague phrases about loose organisation and "professional unapproachableness," but no evidence is produced for the statements, or rather the insinuations, made. It is remarkable that the official organ of the Association of Education Committees should be so ready to expose what it thinks to be the weakness of a service for which its constituent bodies are directly responsible, and when the relatively small cost of the service is considered, the criticism manifests some lack of a sense of proportion. It might more fitly have been directed against those laggard authorities who, by their inadequate staffing and equipment of the service, continue to hinder its efficiency. Of the success of the service in the more progressive areas in producing results there can be no question, and the suggestion of professional incapacity in its organisation is unjustified by facts. Efficiency in the child welfare and school medical services is a premium paid for the health of the nation; any reduction in that efficiency would lead to a return to conditions of former years. The suggestion that reduction of costs would not curtail efficiency shows ignorance of the workings of a service which is an integral part of the general educational system. It is impossible to believe that the article reflects a general feeling among education committees or their chief officials. If it does, it can only be hoped that the control of the school medical service in England will, as in Scotland, be transferred from education committees, and become part of the general health service of the country—as indeed in its activities and purposes it essentially is.

Endocrine Disturbances in School-children

Dr. H. J. Phillips, assistant school medical officer for the county of Kent, has kept a record of all the children during the year who showed endocrine disturbances. Visible enlargement of the thyroid gland was noted in 74 cases—20 boys and 54 girls—the highest figure being in the 13 age-group. Four of the cases showed hyperactivity and, in addition, six children had clinical signs of hyperthyroidism without visible enlargement of the gland. None of these 10 cases had any obvious septic focus; all of them were at or about the age of puberty, a time of mental strain. Dr. Phillips would diagnose hyperthyroidism, whether the thyroid is enlarged or not, in a spare boy or girl, at about the age of puberty, who has tachycardia, fine tremors of the upper limbs, and a tendency to general over-action. The question of treatment is difficult. Experience has shown that in a large number of these cases the symptoms subside without treatment, but the majority pass from the observation of the school service with symptoms still present. Whether they are potential cases of Graves's disease can only be established by careful following-up. Dr. Phillips does not mention that those who have to deal with senior students and teachers find a considerable proportion of hyperthyroidism among those who have to be invalided owing to nervous breakdown. Experienced examiners in fact hesitate to admit candidates who show even slight signs of this condition. Twelve of the children with enlargement of the thyroid gland showed symptoms of the opposite type; though none would have been called a cretin, they had in varying degree the malar blush, the heavy folds between nose and cheek, large tongue, supraclavicular pads of fat, and mental hebetude. None of these children had had any adequate treatment. The majority of the goitrous children showed no sign of either plus or minus thyroid activity, and this might appear to justify a laissez-faire attitude, were it not that simple goitres of months' or of years' standing may quite suddenly become hyperactive and develop into Graves's disease. "I am of opinion," Dr. Phillips writes, "that where treatment can be tried and adequately controlled, there is no justification for withholding it." He advises that every case should be carefully watched, the only sure guide to the functioning of the gland being the estimation of the basal metabolic rate. Such control might readily be available in school clinics, and Dr. Phillips regrets that facilities are not afforded.

Of disturbances of pituitary function there was one case of mild acromegaly, one of infantilism, and 49 cases of Fröhlich's syndrome in varying degree, especially the characteristic deposit of fat, the undeveloped external genitals in the males, and the mental somnolence. Dr. Phillips was struck by this rather large number of such cases found in his area. "Whether the actual incidence is greater in north-west Kent than in the rest of the country," he says, "I have no figures to show, but it is interesting to note that the great classical example of Brissaud's infantilism—viz., the fat boy in 'Pickwick Papers'—was created by the great novelist who wrote so many books based on the very area from which my cases have been drawn." The parents had not secured treatment for any of them, but Dr. Phillips, watching some of the worst over a period of years, noted that the symptoms definitely increased. He would try in every case the effect of compound pituitary gland and diet, plus thyroid extract where indicated; he can cite some striking successes such as that of a boy of 14 with double girdle obesity, infantile genitals, undescended testicles, beginning to get lethargic and dull at school, who after three months' out-patient treatment lost 14 lb. of weight, while the headmaster reported great improvement in his work. Cases like this are a source of satisfaction to all concerned; they offer a good field for coöperation between school medical officer and private practitioner.

The Swindon Maternity Scheme

Last year Dr. D. Brewer completed a scheme for making maternity safe in the borough of Swindon and neighbouring parts of Wiltshire. The new maternity home, claimed to be the last word in efficiency, was opened during the year, two principles, known as the New South Wales convention, being accepted in connexion with it. First, that deaths in childbearing are to be considered due to the reproductive process, unless it is proved to the contrary; secondly, that the temperature of the puerperal woman is to be recorded four-hourly during the first ten days in order that the onset of sepsis may be detected within four hours. Dr Brewer believes that this system of temperature recording, which has the effect of trebling the cases of puerperal pyrexia, will throw material light upon the occurrence of outbreaks of pyrexia, which are frequent in maternity hospitals and other institutions. The working of the home up to now suggests that about half the confinements in the borough will eventually take place there. The home is a recognised training school for midwives, and has an extern department which attended 161 deliveries and 8 miscarriages in 1931, the total number of births being 910. There were two deaths in the town in connexion with reproduction; one was from embolism, and the one death which occurred in the home—the only preventable maternal death of the year—would not have occurred had the woman received the attention which she could have had under the scheme. She was admitted moribund from antepartum hæmorrhage. Natal (including postnatal) clinics under the scheme are of three kinds: those held by the matron and the staff of midwives; those held by the woman medical officer who is inspector of midwives; and those held by the consulting obstetrician. For each patient attending the antenatal department a card is filled in, which is transferable from one clinic to another, and is available for cases delivered in the home or in the extern department, and also for domiciliary cases attended by medical practitioners or midwives. The corporation appoints a rota of practitioners to act as obstetricians to the home on behalf of cases other than those booked by practitioners. The rota consists of two private practitioners and one practitioner, with a deputy, appointed by the G.W.R. Medical Fund Society. The services of the consultant and of an anæsthetist are available for every case. Patients booking for the home as doctors' cases pay their own medical fees. Others are considered as midwives' cases, and admitted at fees varying with their income, but the corporation undertakes to pay all medical fees incurred when the midwife sends for medical assistance. The rules appear to provide for every possible contingency. Scrupulous care is taken to see that only clean cases are admitted to the ordinary wards and labour room, a separate department with its own labour ward being kept for doubtful cases. Cases of puerperal sepsis are referred to the isolation hospital, and sufferers from venereal disease are admitted to the county council's V.D. hospital. Of the 259 cases delivered in the home, instrumental assistance was given in 46—a forceps rate of 18 per cent. There were two induced abortions, one Cæsarean section, six cases of placenta prævia, four of eclampsia, and one of mania. With the exception of the case of placenta prævia (already mentioned) admitted moribund, every case was treated to a successful issue in the home, except for two cases of pyrexia which were removed to the isolation hospital, where they recovered. The scheme has won the appreciation and coöperation of the parturient mothers.

Official Advice on Nutrition

The Advisory Committee on Nutrition after a review of recent research work on this subject has advised the Minister of Health:

(1) Having regard to the cogency of the evidence that nutritional anæmia of infants can be greatly reduced by the administration of iron ammonium citrate, it would be proper for the Ministry to give practical advice on the matter to the medical officers of authorities responsible for the feeding of infants.

(2) The experimental evidence supporting the conclusion that rickets and dental disease can be mitigated or prevented by an adequate supply of vitamin D and calcium-rich foods, such as milk, eggs, cod-liver oil, in the diets of infants and children and of expectant and nursing mothers, is so cogent that it would be proper for the department concerned to call the attention of local authorities to the results obtained in Sheffield, in Birmingham, and elsewhere, and to state that, in the view of the department, these results should be applied.

(3) The Ministry should continue to emphasise the paramount importance of milk in the dietary of growing children.

Circular 1290, dated Oct. 27th, 1932 (H.M. Stat. Office, 2*d.*), implements these recommendations in crisp injunctions to county (borough) councils and other maternity and child welfare authorities. The following is a summary of the circular as given in an appendix.

SUMMARY OF CONTENTS OF CIRCULAR 1290

I. *Nutritional Anæmia in Infancy*

Nutritional anæmia is prevalent among infants, and is due to a deficiency of available iron. It is often present only in a mild degree. In its more severe forms it is found frequently in infants who were under weight at birth. Twins and prematurely born babies are especially liable to be affected.

Its chief feature is an abnormal liability to intercurrent infections, particularly colds, otorrhœa, bronchitis, and enteritis, and a tendency for infections to become chronic.

Nutritional anæmia can be prevented and cured by the administration of iron ammonium citrate to infants, or the feeding of infants with milk to which iron in an appropriate form has been added. Dried milk preparations containing added iron are already on the market.

II. *Rickets and Dental Disease*

Severe rickets is rapidly disappearing in this country generally, but in some areas the milder form of the disease is still widely prevalent among infants and young children.

Faulty dentition is widespread.

Both for the prevention and cure of rickets and to ensure a proper development of the teeth, the diet of pregnant and nursing mothers and of infants and young children should contain a sufficient supply of calcium, phosphates, and vitamin D. Of these, vitamin D is the most likely to be deficient.

The main foods containing vitamin D are fat fish, fish livers, egg yolk, milk, and butter. In cases where, for financial reasons, the purchase of eggs and butter and of adequate supplies of milk is not possible, the value of fat fish, such as herrings, sprats, and mackerel, should be borne in mind. Where margarine is the chief source of fat in a diet, those brands which contain added vitamins A and D should if possible be secured. Vitamin D may also be provided by the regular administration of cod-liver oil.

III. *Milk*

Milk is an almost perfect food. It is rich in calcium and phosphorus; it supplies protein of high biological value which is of great importance in building up a sound physique and good constitution; it provides the infection-resisting and calcifying vitamins A and D, the latter mainly in summer, and it has other nutritive and protective qualities which render it particularly valuable as a food.

The consumption of milk in this country is far below what is desirable, and every opportunity should be taken to draw attention to the merits of milk as food, especially as an article of diet for children.

Typhoid in Yorkshire

In two ridings of Yorkshire epidemics of typhoid fever have occurred during the last few weeks. In the North Riding several cases were reported around Malton in the second week of October, and during the week ended Oct. 29th (Dr. H. Mason tells us) 78 cases were notified in this urban district. In the West Riding the little village of Denby Dale, near Huddersfield, was involved with a total up to Oct. 31st of 71 cases with 6 deaths. We are indebted to Dr. T. N. V. Potts, county medical officer, for an account of the origin and nature of this outbreak.

In every case, Dr. Potts writes, the infecting agent was found to be the *Bacillus typhosus*, and there appears to be little doubt about the original source of infection. A young woman, aged 21, returned from holiday in Scarborough towards the end of August. Her home is one of a group of houses situated on the hillside (Quaker Bottom) 500 yards or so above the Square Wood reservoir which supplies the village of Denby Dale, further down the valley. This woman was notified as suffering from typhoid fever on Sept. 17th, and between Oct. 8th and 20th 50 other cases occurred in the village.

Owing to the proximity to the reservoir of the house occupied by the original case, the local medical officer of health, Dr. J. T. Bleasdell, immediately became suspicious of a contaminated water-supply being the medium of infection and, along with the surveyor, he carried out a careful survey of the gathering ground. The Square Wood reservoir was constructed about 40 years ago and has a capacity of approximately two and a half million gallons. It draws its supply of water from eight or nine springs situated in a semicircular gathering ground, half a mile or so in diameter, immediately surrounding the reservoir, the springs being connected up with the latter by sundry underground pipe lines. There is another spring, the water from which flows down by the side of the reservoir, the resultant stream being known as the Munchliffe Dyke; and it appears that many years ago, upon the introduction of the water-carriage system into the group of houses referred to above, the sewage from these dwellings was connected up by drains with the Munchliffe Dyke. Following upon a careful examination of the sides of the dyke by the surveyor an opening into an old rubble drain was discovered, and after tracing this drain to the other end it was found to be communicating directly with the main spring supplying the reservoir, the contaminated water of the dyke being actually seen to be entering the communicating channel. The most likely explanation of the presence of this rubble drain is that the supply of water from the remaining springs was found to be occasionally inadequate, and for the purpose of augmenting the supply the Munchliffe Dyke was drawn upon. No doubt the existence of this channel between the Munchliffe Dyke and the nearby spring was not known to the persons who were responsible for connecting up water-closets and slop-closets to the dyke when the conversion of the houses to the water-carriage system took place. It does appear, however, that the inhabitants of Denby Dale village, numbering some 1400 persons, will have been drinking contaminated water for many years, and had it not been for the advent of the typhoid patient to the houses in Quaker Bottom, situated above the reservoir, it is likely that this tainted water would have continued to be consumed indefinitely.

The supposed infecting case was removed to hospital on Sept. 19th and the supply of water from the Square Wood reservoir was turned off on Oct. 13th. It has been noted that the great bulk of the cases were notified between Oct. 8th and 20th. The period of maximum infectivity of the water would be during the few days prior to the original patient going to hospital, although the risk of infection would continue until Oct. 13th, when the water from the reservoir was cut off. The foregoing sequence of events is consistent with the suggestion that the Scarborough case was the original source of infection. It was fortunate that the surveyor was able to connect up an alternative supply from the Rusby Wood reservoir. The latter is owned by the urban district council and is used for supplying a number of nearby parishes. No difficulty was experienced in finding the necessary hospital accommodation, and the cases have been sent to the infectious diseases hospitals at Penistone, Meltham, Kirkburton, and Huddersfield. The danger of further infection has disappeared with the cutting off of the infected water-supply, and only by disregard of ordinary preventive measures will any further risk be encountered. The department of the county medical officer at Wakefield has been busily engaged in coöperation with the local medical officer of health. Anti-typhoid vaccine has been supplied by the county department, and the necessary Widal reactions and water examinations have been made in the county laboratory.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED OCT. 22ND, 1932

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 33 (last week, 12); scarlet fever, 2265; diphtheria, 1031; enteric fever, 79; acute pneumonia (primary or influenzal), 848; puerperal fever, 37; puerperal pyrexia, 103; cerebro-spinal fever, 19; acute poliomyelitis, 26; acute polio-encephalitis, 1; encephalitis lethargica, 7; dysentery, 8; ophthalmia neonatorum, 94. No case of cholera, plague, or typhus fever was notified during the week.

Of the cases of small-pox, 24 were reported from the county of London, distributed among the metropolitan boroughs: Bethnal Green, Islington, and Southwark each 1; Stepney 2, Hackney 3, Poplar 16.

The number of cases in the Infectious Hospitals of the London County Council on Oct. 25th–26th was as follows:—Small-pox, 65 under treatment, 4 under observation (last week 49 and 0 respectively); scarlet fever, 1926; diphtheria, 1720; enteric fever, 19; measles, 228; whooping-cough, 327; puerperal fever, 24 (plus 10 babies); encephalitis lethargica, 231; poliomyelitis, 6; "other diseases," 161. At St. Margaret's Hospital there were 15 babies (plus 7 mothers) with ophthalmia neonatorum.

Deaths.—In 117 great towns, including London there was no death from small-pox, 2 (0) from enteric fever, 5 (0) from measles, 6 (1) from scarlet fever, 11 (2) from whooping-cough, 21 (3) from diphtheria, 70 (22) from diarrhœa and enteritis under two years, and 50 (7) from influenza. The figures in parentheses are those for London itself.

Birkenhead and Liverpool each reported a fatal case of enteric fever. Diarrhœa was credited with 10 deaths at Liverpool, 4 each at Leeds, Manchester, and Birmingham. Liverpool reported 4 deaths from diphtheria.

The number of stillbirths notified during the week was 249 (corresponding to a rate of 39 per 1000 births), including 26 in London.

OBITUARY

ANDREW FREELAND FERGUS, M.D., F.R.F.P.S., LL.D. Glasg.

THE death of Dr. Freeland Fergus, the well-known ophthalmologist, was announced last week. It occurred on Oct. 24th at his residence, Fernycrag, Rothesay, in the seventy-fifth year of his age. He was the son of Dr. Andrew Fergus, of Glasgow, a well-known sanitarian and formerly president of the Royal Faculty of Medicine and Surgery, Glasgow.

Andrew Freeland Fergus was educated at the University of Glasgow, where he graduated M.B., C.M., in 1888. After holding several resident appointments he decided to make ophthalmology a specialty, and with that purpose studied under Snellen at Utrecht for a considerable period. On his return he was elected to the staff of the Glasgow Eye Infirmary and shortly afterwards to the Royal Infirmary, Glasgow. With these large fields of observation open to him he rapidly became a recognised authority in his subject. He translated Meyer's Diseases of the Eye, and published a certain number of sound papers in medical journals. At Anderson's College he was elected professor of ophthalmology, and lectured at the institution while he was also an examiner in ophthalmology at the Royal Faculty of Physicians and Surgeons, of which corporation he became President.

His public and professional work were equally distinguished. He was among the most energetic of those who promoted the existing machinery for the examination of the blind in Scotland, and became president of the Scottish National Federation of Institutions and Societies for the Blind. He was a medical referee under the Workmen's Compensation Act, and the locality of his activities gave him a fruitful opportunity for observing miners' nystagmus. His views on the treatment, and especially on the question of unfitness for work of the subjects of this disease, were clear-cut and valuable, and he became a recognised authority on the subject, collecting information from many sources in Europe and America. He wrote on the subject in THE LANCET, among other places, but he was not a frequent author, publishing only one small volume on elementary ophthalmic optics in 1903. During the war Prof. Fergus worked with great assiduity in examining the eyes of recruits and treating eye diseases among the soldiers, especially in the 4th General Scottish Hospital, and for these services he was officially commended. In addition to the appointments mentioned he was also president of the Glasgow Medico-Chirurgical Society, vice-president of the Glasgow Art Club, and president of the Royal Philosophical Society of Glasgow, of which institution he was for many years honorary secretary.

Dr. Fergus, who was unmarried, was the brother of Dr. John Fergus, who has also filled the presidential chair of the Royal Faculty; the two sons following in the steps of the father.

LAWRIE HUGH McGAVIN, C.B.E., F.R.C.S. Eng.

WE regret to announce the death of Mr. Lawrie McGavin, which occurred on Oct. 31st at Folkestone, in the sixty-fourth year of his age.

Lawrie Hugh McGavin was born in 1868, the son of Mr. John McGavin, of Calcutta. He was educated at Fettes College and Sandhurst, his original intention being to join the army. But in 1893 he entered Guy's Hospital as a student, obtained the English double qualification in 1898, and, after filling the usual resident appointments, became F.R.C.S. Eng. in 1890. At Guy's he held the post of surgical registrar, and later became surgeon to the Women's Hospital, Soho, and the North-West London Hospital. At the time of his death he was consulting surgeon to the Women's Hospital and the Dreadnought Hospital, Greenwich. During the war he held a number of hospital appointments, being surgeon to King George's Hospital, the Endsleigh Hospital for Officers, and the Michie Red Cross Hospital, while he was also a member of the final appeal board of medical assessors. For these services he was created C.B.E.

Mr. McGavin married in 1892 Edith Mary, daughter of the late Horatio Beauchamp, of Melbourne.

MEDICAL NEWS

Royal College of Physicians of London

At a comitia of the College on Oct. 27th, with Lord Dawson, the president, in the chair, Dr. H. C. Cameron, Dr. W. E. Hume, Sir Hubert Bond, and Dr. W. W. Jameson were elected councillors. The following were elected representatives of the College: Dr. H. Letheby Tidy as a member of the committee of management of the Conjoint Examining Board; Dr. Comyns Berkeley on the Central Midwives Board; Dr. J. H. Abram on the court of governors of the University of Liverpool; Dr. A. S. Barnes on the court of governors of Birmingham University; and Sir Stanley Woodwark on the Central Council for District Nursing. The president announced that Sir George Buchanan had been appointed Milroy lecturer for 1934, and that the Jenks memorial scholarship for 1932 had been awarded to Gerald Sutherland Irvine, late of Epsom College.

The FitzPatrick lectures on the Development of Neurology from the Commencement of the Nineteenth Century to the Present Time will be delivered by Dr. James Collier on Nov. 8th and 10th, and the Lloyd Roberts lecture on the Liberal Education of the Body by Prof. L. P. Jacks on Nov. 22nd, *all at 5* P.M.

The following candidates, having satisfied the Censors' Board, were elected to the membership:—

Ernest Henry Capel, M.B. Lond.; Paul Ward Farmer, Jnr., M.B. Melb.; Clifford Gordon Gordon-Wilson, L.R.C.P.; Harold Kingston Graham Hodgson, M.B. Durh.; Robert Dennis Harding, L.R.C.P.; Reginald St. Alban Heathcote, M.D. Oxf.; John Collinson Heather, M.B. Lond.; Henry Lovell Hoffman, M.B. Camb.; Henry Robert Holmes, M.B. Lond.; Max Honigsberger, L.R.C.P.; Harry Barlow Jackson, M.B. Lond.; Geoffrey Hales Jennings, L.R.C.P.; Rajmal Kasliwal, M.B. Lucknow; Eldon Munro Litchfield, L.R.C.P.; Herbert Geoffrey McComas, M.B. Lond.; Arthur Ian Granville McLaughlin, M.B. Sydney; Ian Gideon McLean, M.D. Melb.; Willson Alexander McTavish, M.D. Toronto; George Douglas Morgan, L.R.C.P.; Richard John Langford O'Donoghue, M.B. Lond.; Harold Anstruther Palmer, M.B. Manch.; Kallenkarai Narayana Pisharoty, M.B. Madras; William Gordon Robson, M.B. Edin.; David Paul Hannaford Schafer, M.B. Melb; Philip Graham Stock, M.B. Bristol; Ramaier Viswanathan, M.D. Madras; John Frederick Wilkinson, M.D. Manch.; and John Alan Bruce Young, M.B. Edin.

Licences to practise were conferred upon 130 candidates, 113 men and 17 women, who have passed the final examination of the Conjoint Board and have complied with the by-laws of the College. The following are the names and medical schools of successful candidates:—

Mary-Ann C. Adams, Royal Free; R. M. Alford, St. Thomas's; J. C. G. Anderton, Camb. and Westminster; H. J. B. Atkins, Oxford and Guy's; R. H. Bailey, Camb. and King's Coll.; Helen Baker, Royal Free; N. J. Bakhru, M.B. Bombay, West London; J. B. Bamford, St. Bart.'s; P. Baron, M.B. Cape Town; S. A. Bather, Oxford and St. Mary's; T. P. Binns, Guy's; M. S. W. Bisdee, Tasmania and St. Mary's; E. N. Brockway, St. Thomas's; Doris B. Brown, M.B. Leeds; R. C. Brown, St. Thomas's; R. H. Brown, Camb. and Westminster; W. M. Capper, St. Bart.'s; P. K. Chanmugam, L.M.S. Ceylon, King's Coll.; E. M. Clark, St. Bart.'s; C. A. Clarke, Camb. and Guy's; C. C. Cobb, Oxford and St. George's; J. C. Colbeck, Guy's; N. C. Coombs, Camb. and Bristol; S. W. Cooper, St. Mary's; S. M. Cruz, Madras and Birmingham; A. R. Cutlack, St. Bart.'s; Joan M. C. Dancy, Royal Free; A. L. Davies, Middlesex; Doris A. Dean, Birmingham; R. A. Desai, M.B. Bombay, West London; Phyllis M. Dobbs, Camb. and Royal Free; Joan C. Drury, Camb. and Royal Free; Evelyn M. Eggleton, Univ. Coll.; G. M. Evans, Bristol; R. C. Evans, Univ. Coll.; J. Fishman, London; L. P. Fitch, St. Thomas's; Fanny C. Fraser, Royal Free; T. H. Gardener, London; D. W. Geidt, Guy's; W. G. Gill, Camb. and Guy's; J. A. S. Goonawardena, L.M.S. Ceylon, Univ. Coll.; W. B. Gough, M.B. Birmingham; E. H. B. Grey, London; H. C. P. Gunewardene, L.M.S. Ceylon, St. Bart.'s; B. P. Harris, Camb. and Middlesex; Augusta G. Harrison, Charing Cross; C. L. Hay-Shunker, Madras and St. Bart.'s; O. S. Heyns, Cape and Univ. Coll.; E. A. Hoare, St. Thomas's; Phyllis L. Holliday, Camb. and Leeds; H. D. Holt, Univ. Coll.; A. W. J. Houghton, St. Bart.'s; T. G. F. Hudson, St. Thomas's; Elizabeth M. Hutton, Royal Free; W. A. Hyslop, London; R. James, St. Mary's; N. D. Jekyll, Camb. and London; Ruby D. Johnson, Oxford and Univ. Coll.; W. H. Jones, Manchester; F. R. Kitchin, M.B. Liverpool; R. G. Knight, Camb. and Guy's; S. Levontin, London; B. S. Lewis, St. Bart.'s; W. Lewis, Camb. and Guy's; D. P. Lockhart, St. Thomas's; Barbara R. Lockwood, Royal Free; J. Lubran, Guy's; J. J. McCann, St. Thomas's; D. C. McClure, London; D. U. MacDonald, Leeds; M. B. McGinn, London; S. A. MacKeith, St. Mary's; V. S. Majmudar, M.B. Bomb., Birmingham; K. Malik, L.D.S. Eng., London; J. B. Maurice, Oxford and St. Mary's; I. R. W. Merrick, King's Coll.; C. J. Morgan, Cardiff and St. Bart.'s; F. P. Morgan, M.B. Melbourne; H. F. Moseley, Oxford and St. Thomas's; N. J. S. Nathan, Charing Cross; G. F. O'Connor, Camb. and Birmingham; Elizabeth M. Ogden, King's Coll.; G. Y. Oon, Charing Cross; M. W. L. Owen, Camb. and St. Mary's; R. Q. Parkes, Camb. and St. Thomas's; R. V. Payne, Camb. and Guy's; H. E. Pearse, Bristol; C. J. P. Pearson, St. Thomas's; G. E. Phillips, Cardiff; R. W. Pickering, Cape and Guy's; W. S. Pitt-Payne, L.M.S.S.A. Lond., Guy's; E. C. Powell, Guy's; F. J. P. Price, Cardiff and King's Coll.; R. G. Pulvertaft, Camb. and St. Thomas's; F. Ridehalgh, Camb. and Charing Cross; A. E. A. Ridgway, A.M.I.Mech.E., Charing Cross; B. F. B. Russell, St. Bart.'s; H. K. B. Rustogi, M.B. Lucknow, West London; V. M. Seifert, London; M. Shankla, M.B. Leeds; B. Sharma, M.B. Punjab, London; R. T. Shipman, St. Thomas's; S. C. Shore, Cape and Guy's; J. P. Singer, Camb. and Guy's; H. Singh, Punjab and Birmingham; V. C. Snell, Camb. and St. Bart.'s; W. H. C. Spooner, St. Mary's; E. J. Stubbs, Guy's; R. Sykes, Manchester, J. W. C. Symonds, St. Bart.'s; A. E. Terry, Leeds; Jessie A. Thirtle, Royal Free; H. H. Thompson, Manchester; J. R. Thornton, St. Thomas's; T. M. Tyrrell, Camb. and St. Thomas's; Patricia I. Unsworth, Liverpool; H. B. D. Vaughan, St. Bart.'s; C. B. M. Warren, Camb. and St. Bart.'s; W. H. C. Watson, Camb. and St. Thomas's; G. C. Welply, St. Mary's; J. H. West, St. Bart.'s; H. M. Williams, St. Bart.'s; H. V. Williams, Univ. Coll.; H. R. I. Wolfe, St. Thomas's; L. J. Wolfson, Guy's; T. G. R. Woods, St. Bart.'s; S. W. Wright, Guy's; H. W. Wykes, Middlesex; and K. E. L. Yuill, Birmingham.

Diplomas in Public Health were conferred (jointly with the Royal College of Surgeons) upon the following 15 candidates:—

N. D. Begg, R. Evans, J. Galea, P. Henderson, C. B. Huss, Dorothy M. James, E. T. James, H. N. C. van G. Kelaart, I. B. Lawrence, W. D. Lovelock-Jones, B. S. Nanjiani, T. St. M. Norris, J. A. D. Radcliffe, R. E. Robinson, and L. A. S. Trott.

Society of Apothecaries of London

At recent examinations the following candidates were successful:—

Surgery.—G. W. Aston, Univ. Coll. Hosp.; F. W. Baskerville, St. Mary's Hosp.; R. N. O'D. Burns, Univ. of Bristol; M. B. Chandulal, Hongkong and Univ. Coll. Hosp.; W. E. P. Corbett, St. Mary's Hosp.; C. H. Fagge, Univ. of Oxford and Guy's Hosp.; F. M. F. Forrest, St. Mary's Hosp.; A. J. McBrearty, Queen's Univ., Belfast; M. N. Mandelstam, Univ. of Witwatersrand and Middlesex Hosp.; J. W. Meyers, King's Coll. Hosp.; A. E. A. Ridgway, Charing Cross Hosp.; H. Shukry, Univ. of Cairo and Univ. Coll. Hosp.; and R. H. Wheeler, Univ. of Sheffield.

Medicine.—J. L. Bates, Guy's Hosp.; E. F. David, Univ. of Cologne and Royal Free Hosp.; J. O. Gordon, Middlesex Hosp.; J. Harris, Univ. of Witwatersrand and Middlesex Hosp.; E. J. Littledale, Guy's Hosp.; A. J. McBrearty, Queen's Univ., Belfast; S. Pugmire, Univ. of Liverpool; H. Shukry, Univ. of Cairo and Univ. Coll. Hosp.; and M. Sourasky, Charing Cross Hosp.

Forensic Medicine.—E. L. Burgess, King's Coll. Hosp.; J. L. Cope, Univ. of Cambridge and Westminster Hosp.; K. M. Hahn, Middlesex Hosp.; J. E. Morrish, St. Mary's Hosp.; S. Pugmire, Univ. of Liverpool; P. J. Purcell, St. Mary's Hosp.; H. Shukry, Univ. of Cairo and Univ. Coll. Hosp.; and B. K. Siddhante, Calcutta Med. Coll.

Midwifery.—F. M. F. Forrest, St. Mary's Hosp.; K. M. Hahn, Middlesex Hosp.; D. Kyle and P. J. Purcell, St. Mary's Hosp.; B. K. Siddhante, Calcutta Med. Coll.; and R. C. P. Thomas, St. Mary's Hosp.

The following candidates, having completed the final examination, are granted the diploma of the society entitling them to practise medicine, surgery, and midwifery: R. N. O'D. Burns, M. N. Mandelstam, M. B. Chandulal, J. W. Meyers, C. H. Fagge, S. Pugmire, A. J. McBrearty, and A. E. A. Ridgway.

A Livery dinner will be given by the Master and Wardens of the society in the Apothecaries' Hall, Blackfriars, on Tuesday, Nov. 15th, at 7.30 P.M.

British Institute of Philosophy

Sir Arthur Eddington, F.R.S., will deliver an address on Physics and Philosophy at University College, Gower-street, London, W.C., at 8.15 P.M. on Tuesday, Nov. 15th. Tickets may be had on application to the director of studies, University Hall, 14, Gordon-square, W.C. 1.

University of London

At a meeting of the Senate on Oct. 26th it was decided that the title of the university chair of physiology at the Middlesex Hospital medical school should now be the John Astor chair of physiology. It has lately been announced that Major J. J. Astor, M.P., was the anonymous donor who endowed the chair with £20,000 in 1920.

In consequence of the gift of £1500 a year for seven years from the Prudential Assurance Company for the endowment of the chair of public health tenable at the London School of Hygiene and Tropical Medicine, it was decided that the chair should be known as the Prudential chair of public health for the duration of the gift.

The degree of D.Sc. in biochemistry was conferred on Dr. E. C. Dodds, Courtauld professor of biochemistry at the Middlesex Hospital medical school.

The University College Committee have elected Sir John Rose Bradford, F.R.S., as chairman in succession to Lord Chelmsford.

Sir Charles Sherrington, O.M., will deliver two lectures on Reflex Action, at University College, Gower-street, London, on Thursdays, Nov. 17th and 24th, at 5.30 P.M. No ticket is required for admission.

University of Manchester

Dr. A. N. Birkett has been appointed demonstrator in anatomy.

National University of Ireland

Dr. Walter Fallon has been appointed professor of medicine in University College, Galway.

Guy's Hospital

Dr. C. H. Rogerson has been appointed to the Sir Alfred Fripp memorial Fellowship in child psychology, tenable at Guy's Hospital.

National Institute of Industrial Psychology

Lord Macmillan has agreed to succeed Lord D'Abernon as president of this institute. Lord D'Abernon, who has had to resign owing to the pressure of other engagements, succeeded the late Lord Balfour in 1930.

The Place of Biology in Education

In connexion with the conference on this subject, to be held in London on Nov. 30th and Dec. 3rd (see THE LANCET, Oct. 29th, p. 977), a public meeting will be held at the Essex Hall, Essex-street, Strand, W.C., at 6.30 P.M. on Thursday, Dec. 1st. The subject of discussion will be Biology and Education, and the principal speakers will be Dame Helen Gwynne-Vaughan and Prof. A. C. Seward, F.R.S. No tickets are required.

Burton Infirmary Enlargement

Lady Evershed, wife of Sir Herbert Evershed, the chairman, recently opened extensions of Burton-on-Trent Hospital. The works now include a casualty department, an extension of the out-patients' department generally, an ear, nose and throat theatre, a clinic for social hygiene work, a new dispensary and secretarial offices, and a large X ray department. Three wards have been added, and the nurses' and staff quarters enlarged.

Conference on Mental Welfare

A conference on mental welfare will be held at B.M.A. House, Tavistock-square, London, W.C., on Dec. 1st and 2nd. At the first meeting, it is hoped, Sir Hilton Young, the Minister of Health, will open the proceedings; the chairman will be Sir Leslie Scott, and the subject of discussion Problems of Mental Health Work. At the second meeting, on Thursday afternoon, Sir Henry Brackenbury will take the chair, and Dr. R. Ashleigh Glegg will open a discussion on the Social Control of Feeble-minded Children leaving Elementary Schools. On Friday morning Mr. L. G. Brock, chairman of the Board of Control, will preside, and Mr. E. J. Lidbetter will speak on the Inheritance of Mental Deficiency. The last meeting will be devoted to School Retardation as a Factor in certain Conduct Problems of Childhood and Adolescence. Further particulars may be had from the secretary of the Central Association for Mental Welfare, 24, Buckingham Palace-road, London, S.W.1.

Hampstead General Hospital

At the opening of the third winter session of lectures at this hospital on Oct. 26th, under the chairmanship of Sir William Collins, an address was delivered by Sir Ernest Graham-Little, M.P., on the future of the voluntary hospital system. The lecturer gave the arguments, with figures, to support the following propositions: (1) that the voluntary hospitals are in a stronger position financially and morally at the present moment than at any time in recent history; (2) that they command a tradition of service and humane consideration which cannot be imitated by any institutions lacking their long organic growth; (3) that the administration of a voluntary system must be incomparably cheaper than that of any State-controlled system; and (4) that the functions of advancing teaching and research, discharged by the voluntary hospitals, cannot be supplied by institutions functioning under either State or municipal control. Sir Ernest found pessimism as to the future of the voluntary hospitals quite unjustified in the face of the figures quoted by the Prince of Wales at the meeting of the King Edward's Hospital Fund for London last June, which demonstrated the vastly improved position of the previous year; while he reminded the audience of the notable rebuilding operations carried out recently by the London, King's College, Middlesex, University College, Guy's, and St. Mary's Hospitals, solely upon voluntary subscriptions. Sir Ernest, regretting the attitude of the British Hospitals Association, considered that the acceptance of money derived from sweepstakes would be disastrous to the voluntary principle, and quoted a report of King Edward's Hospital Fund to prove that the voluntary hospitals are becoming largely a coöperative effort in which all classes of the community, including the patients, are joining. He closed with a demand for a drastic alteration of the medical curriculum, so that it may fit the needs more closely of the student who is ring general practice.

Annual Dinners

The annual dinner of the Royal Society of Medici will be held on Thursday, Nov. 17th, at the May Fair Hot London, W., Mr. Warren Low, the president, in the chair.

The annual dinner of the British College of Obst ricians and Gynæcologists will be held on Monday, Dec. 5 at Grosvenor House, London, W., at 7.30 P.M. At 3 P on the same day, H.R.H. the Duchess of York will [illegible] the ceremony in connexion with declaring open the Ho of the College, 58, Queen Anne-street, London, W.

The annual dinner of the Medico-Legal Society be held at the Holborn Restaurant, London, on Frid Dec. 9th, at 7 P.M.

The annual dinner of the Prince of Wales's H [illegible] will be held at the Trocadero Resta [illegible]., on Thursday, Nov. 24th, at 7.45 [illegible] with Dr. C. E. Sundell in the chair. The sec[illegible] is Dr. Bertram H. Jones, 47, Queen Anne-street, W. 1.

Liverpool Society of Anæsthetists

An ordinary general meeting of this society, with A. J. O'Leary, the president, in the chair, was held at David Lewis Northern Hospital, Liverpool, on Oct. Dr. I. W. Magill, of the Westminster Hospital, Lond gave a demonstration in blind nasal intubation thesia, and a short discussion followed.

The society was formed in July, 1930, and has a ship of 26 ordinary and 9 honorary members. hon. secretary is Dr. R. J. Minnitt.

New Hospital at Papworth

On Friday last Lady Baron laid the foundation-ston a hospital at this tuberculosis settlement. There wil accommodation for 84 in-patients, and the out-patie department will serve the whole of the village. The B hard Baron trustees have contributed £20,000 towards cost. The building has been designed by Mr. M manager of the building department of the settlement, Mr. Copsey, both of whom have been patients, and hospital will, as far as possible, be erected by skilled in the colony.

Nottingham General Hospital

The Lord Mayor of Nottingham, Alderman W. Gr has recently opened the new "W. G. Player Wing" Nottingham General Hospital, which replaces tempo huts erected in 1916. The entire cost, £23,000, has defrayed by Mr. Player, an anonymous donor has provi the equipment, and the linen has been paid for by the Guild. The new building, which is a male block, is of one-storey type, and is nearly 400 feet long. It two large and two small wards, with a total of 36 bed patients' day-room, a laboratory, and a clinical room other necessary accommodation.

Maternal Mortality Committee

This committee, whose chairman is Mrs. H. J. Tenn has arranged for a meeting at Friends House, Euston-r London, N.W., at 2.30 P.M., on Tuesday, Nov. 15th. L Iveagh, the hon. treasurer, will preside, and an add will be given by Sir Hilton Young, the Minister of Hea The committee came into existence about six years in order to bring the influence of all women to bear on question of maternal mortality. At the meeting, it is sta a resolution will be proposed pressing for improvem in the care of mothers before and after childbirth, an better standard of nursing and better training for doct It will also urge "the putting into force of all the serv for the protection of motherhood which the local authori can use, and which form the nucleus for that comprehens national maternity service which all in touch with moth hood are anxious to see established." Tickets may had from the secretary, Miss Tuckwell, C.H., 13, Ches terrace, S.W.1.

Harrow and Wealdstone Hospital

On Saturday afternoon last a performance of Mr. J. McCarthy's "If I were King" was given by the Trin College Dramatic Company, under the direction of F. G. Lloyd, at the New Scala Theatre, for the benefit the Harrow and Wealdstone Hospital, which celebrates t year the twenty-fifth anniversary of its opening. La Patricia Ramsay represented Princess Louise, who oper the hospital in 1907, and was to have been present on t "silver wedding" occasion had the weather not been unfriendly. The house was full of patrons of the hospi and college, who were warmly appreciative of the way which the piece was staged and played. At the conclusi Mr. Sydney Walton, as president of the hospital, express the thanks of the governors to the members of the ca and revealed an engagement of a permanent charact between two of the principal actors. The entr'acte mus conducted by Mr. Henry Geehl, was in keeping with t high level of the acting.

Grocers' Research Scholarships

To encourage original research in sanitary science the Grocers' Company offers scholarships of £300, tenable for one year and renewable for a further term, together with grants towards expenses. Particulars will be found in our advertisement columns.

Royal Photographic Society of Great Britain

An exhibition of cinematography will be held at the galleries of this society, 35, Russell-square, London, W.C., from Nov. 14th to Dec. 10th. An attempt will be made "to place before the public a comprehensive set of exhibits demonstrating the history of cinematography and its present-day applications." A series of evening meetings will be held during the exhibition, at which apparatus will be demonstrated and films projected. The one on Thursday, Nov. 24th, will be devoted to science, medicine, natural history, and research. Admission to the exhibition is free, and seats for the lectures can be reserved.

Enlargement of Worcester Infirmary

On Friday last the Prince of Wales opened extensive enlargements of this hospital, which have cost £60,000; the scheme, when completed, will have cost £90,000. The new works include an orthopædic block, a pathological laboratory, two theatres, and a nurses' home. The last-named, which is connected with the hospital by a covered passage, accommodates 62 nurses, and among its amenities is a hairdressing room. One of the rooms will be used as a coroner's court.

Ormond Maternity Trust

In aid of the advanced post-graduate courses in midwifery organised by this trust in connexion with the Queen's Institute of District Nursing, three lectures will be given in London during November. On Wednesday, the 9th, at 3.15 P.M., at 1, Cadogan-gardens, S.W., Mrs. Stanley Baldwin will preside, and Mr. L. Carnac Rivett, assistant obstetric surgeon to the Middlesex Hospital, will speak on the use of anæsthetics in midwifery. On Thursday, the 17th, at 5.30 P.M., at 25, Lennox-gardens, S.W., Miss Darbyshire, matron of University College Hospital, will give an address on the Report of THE LANCET Commission on Nursing. Both Miss Darbyshire and the chairman, Mr. Lister Harrison, were members of the Commission. The third lecture will be given at Queen's College, 43, Harley-street, W., at 5.30 P.M. on Thursday, Nov. 24th. Lady Salisbury will preside, and Dr. J. S. Fairbairn, president of the British College of Obstetricians and Gynæcologists, will speak on the Maternal Mortality Report. Tickets for the lectures may be had from Mrs. Bruce Richmond, 3, Sumner-place, London, S.W. 7.

The Government and Local Expenditure

In the absence of the Minister of Health, Mr. Geoffrey Shakespeare, Parliamentary Secretary to the Ministry, received on Oct. 31st a deputation from the Public Economy Association of South Wales and Monmouthshire, which represents almost all the industries in that district, local chambers of commerce, trade associations, and landowners. All the speakers stressed the decline of trade in South Wales since the war, and especially in the last two or three years. At the same time, they said, the expenditure of local authorities, both on capital and on revenue account, had greatly increased, and the burden on the depressed industries of the area was now so crushing that there was a real danger of collapse. The deputation suggested that the Minister of Health should refuse to sanction any further borrowing, except in cases of urgency, and even then only after careful inquiry into the future effect on local industry. He should also encourage, where possible, the conversion of outstanding loans to lower rates of interest, or, if necessary, obtain powers to this end. Thirdly, local authorities should be pressed to dispose of uneconomic trading undertakings to private enterprise. When the expenditure of a particular local authority was established to be grossly excessive, the Minister should supersede them and appoint a commissioner. In the course of his reply Mr. Shakespeare explained that the Government's policy was to restrict very severely the incurring of fresh capital expenditure on services not likely to be remunerative. The success of the conversion of war loan made it much easier for local authorities to convert their own loans on favourable terms. As regards trading undertakings run at a loss, it must be recognised that it might sometimes be difficult to induce private enterprise to take them over. The suggestion to appoint commissioners implied, of course, a fundamental break with the traditions of English local government; there had been a temporary power—which had been exercised in a few cases—to appoint commissioners for poor-law purposes, but this had now lapsed.

The Infants Hospital

On Monday last H.R.H. the Princess Royal, president of the hospital, opened the new out-patient department in Bentinck-street, Westminster, part of a much-needed extension scheme which has been made possible principally by the generosity of Sir Gomer Berry, the chairman, and Sir Robert Mond, the treasurer and founder. The new department, which was described in our issue of Oct. 8th (p. 810), is constructed on modern lines, with medical, surgical, ophthalmological, dental, and ear, nose, and throat consulting-rooms, and a well-equipped operating theatre for minor operations. There are also special rooms for X ray work, light treatment, and massage, and a large waiting hall with a refreshment bar adjoining. On the top floor of the building, but wholly disconnected from the out-patient department, there will be a fully equipped milk laboratory with dietetic kitchen, and in the basement there will be five isolation rooms for out-patients, a pathological laboratory, a post-mortem room, and a mortuary and chapel. It is hoped that a new in-patient block, which will raise the number of beds from 50 to 100, will be ready by the middle of next year. This block will include private wards for paying patients, special wards for nursing mothers, a complete operating theatre suite and administrative offices.

Appointments

London County Council: RAE, L. J., M.B., B.Ch., Radiologist, St. Nicholas' Hospital. MONTGOMERY, S. K., M.D. Lond., Radiologist, Hammersmith Hospital.

Vacancies

For further information refer to the advertisement columns

Barrow-in-Furness County Borough.—Asst. M.O. £500.
Bedford County Hospital.—Second H.S. At rate of £140.
Belgrave Hospital for Children, 1, Clapham-road, S.W.—Asst. Surgeon. 50 gns.

Worcester General Infirmary.—Third Res. M.O. £120.
York County Hospital.—H.P. £150.

The Chief Inspector of Factories announces a vacancy for a Certifying Factory Surgeon at Porlock (Somerset).

Medical Diary

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

Tuesday, Nov. 8th.—5 p.m., Therapeutics and Pharmacology. Paper: Dr. E. P. Poulton: The Nature of the Action of Insulin and Some Results with High Carbohydrate and Low Fat Diet. 8.30 p.m., Psychiatry. Dr. Henry Devine: The Problem of Schizophrenia. (Presidential address.)

Friday.—5.30 p.m., Clinical. (Cases at 4.30 p.m.) Cases: Dr. H. V. Morlock: 1. Hæmopneumothorax. Prof. J. M. Woodburn Morison: 2. Myelomata Successfully Treated With X Rays. Dr. Terence East: 3. Hypertrophic Osteo-arthropathy. Dr. Philip Ellman: 4. Angina Pectoris with Recent Coronary Thrombosis, Infarction, and Cardiac Aneurysm. 5. Pulmonary Tuberculosis Treated with Insulin. Dr. Geoffrey Konstam: 6. Pre-gangrenous Changes in a Finger Due to Senile Arterial Degeneration. 7. Ophthalmoplegic Migraine. Dr. C. Newman: 8. Subconjunctival Hæmorrhage with Splenic Enlargement. Other cases will be shown. 8.30 p.m., *Ophthalmology*. (*Cases at 8 p.m.*) Paper: Mr. E. D. D. Davis: Three Cases to Illustrate Modified Toti's Operation for Lacrymal Obstruction, with X Ray Photos of Dilatation of the Lacrymal Sac Reinforced by the Injection of the Sac with Lipiodol. Cases will be shown.

HARVEIAN SOCIETY OF LONDON.

Wednesday, Nov. 9th.—8.30 p.m. (at Paddington Town Hall), Prof. Grey Turner: "Nil Desperandum."

SOUTH-WEST LONDON MEDICAL SOCIETY, Bolingbroke Hospital, Bolingbroke-grove, Wandsworth Common, S.W.

Wednesday, Nov. 9th.—9 p.m., Dr. J. A. Torrens: Consideration on the Treatment of Certain Common Medical Conditions.

MEDICAL SOCIETY OF INDIVIDUAL PSYCHOLOGY, 11, Chandos-street, Cavendish-square, W.

Thursday, Nov. 10th.—8.30 p.m., Dr. J. S. Fairbairn: Psychology in Gynæcological and Obstetric Practice, followed by Dr. Marjory Edwards and other speakers.

PADDINGTON MEDICAL SOCIETY.

Tuesday, Nov. 8th.—9 p.m., in the Great Western Royal Hotel, Paddington. Dr. Ernest Jones: The Significance of Psycho-analysis in Modern Medicine.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.

Friday, Nov. 11th.—Dr. Donald Paterson: Some Advances in Pædiatrics.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, S.W.

Tuesday, Nov. 8th, and following Thursday.—5 p.m., Dr. James Collier: The Development of Neurology from the Commencement of the Nineteenth Century to the Present Time (FitzPatrick Lectures).

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn-fields, W.C.

Monday, Nov. 7th.—5 p.m., Mr. R. Davies-Colley: Tumours of the Jaw (Museum demonstration).

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

Monday, Nov. 7th, to Saturday, Nov. 12th.—Medical Society of London, 11, Chandos-street, Cavendish-square, W. Series of Lectures on Renal Disease. Tues., at 4 p.m., Lecture by Dr. A. Arnold Osman on Nephritis and Nephrosis. (Free to Members.)—West End Hospital for Nervous Diseases, 73, Welbeck-street, W. A Course in Neurology daily at 5 p.m.—Royal Waterloo Hospital, Waterloo-road, S.E. A Course in Medicine, Surgery, and Gynæcology. Nov. 7th to 26th. Afternoons and some mornings.—Hospital for Consumption, Brompton, S.W. A Course in Practical Pathology dealing with Laboratory Methods and the Interpretation of Results. Thurs., at 11.45 p.m. Limited to 6.—10, Bedford-square, W.C. Clinical Pathology Demonstration by Dr. A. Knyvett Gordon on Wed., at 8.30 p.m. (specially suitable for M.R.C.P. candidates), on Splenic Enlargement.—These Courses are open only to Members of the Fellowship of Medicine.

NATIONAL HOSPITAL, Queen-square, W.C.

Monday, Nov. 7th.—2 p.m., Dr. Riddoch: Out-patient Clinic. 3.30 p.m., Dr. Kinnier Wilson: The Motor System.

Tuesday.—2 p.m., Dr. Walshe: Out-patient Clinic. 3.30 p.m., Dr. Martin:

Wednesday.—2 p.m., Dr.
3.30 p.m., Dr. Collier:

Thursday.—2 p.m., Dr. Kinn
3.30 p.m., Dr. Kinnier

Friday.—2 p.m., Dr. Adie:
Dr. Bernard Hart: Psychoneuroses.

WEST LONDON HOSPITAL POST-GRADUATE
Hammersmith-road, W.

Monday, Nov. 7th.—10 a.m., Skin Department, Surg Wards. 2 p.m., Eye and Gynæcological Out-patients 4.15 p.m., Lecture, Mr. Sinclair: Gastric and D Ulcers.

Tuesday.—10 a.m., Medical and Surgical D
2 p.m., Throat, Nose, and Ear Out-patients. 4.15 p.m. Lecture, Dr. Ironside: The Nervous System.

Wednesday.—10 a.m., Medical Wards, Children's Out patients. 2 p.m., Eye Out-patients. 4.45 p.m., V. Diseases Demonstration.

Thursday.—10 a.m., Neurological Out-patients, Demonstration. 2 p.m., Eye and Genito-urina Out-patients. 4.15 p.m., Lecture, Mr. Davenport Injuries to the Eye.

Friday.—10 a.m., Medical Wards, Skin D
2 p.m., Throat, Nose, and Ear Out-patients. 4.15 p.m. Lecture, Dr. Ironside: The Nervous System.

Saturday.—10 a.m., Medical Wards, Children's Out patients, Surgical Wards.

Daily, 2 p.m., Operations. Medical and Surgical Out patient Departments.

The lectures at 4.15 p.m. are open to all medical without fee.

HAMPSTEAD GENERAL AND NORTH-WEST LOND HOSPITAL POST-GRADUATE SCHOOL.

Wednesday, Nov. 9th.—4 p.m., Mr. A. Clifford Morson Psychological and Clinical Results of Division of Vas Deferens.

GLASGOW POST-GRADUATE MEDICAL ASSOCIATION.

Wednesday, Nov. 9th.—4.15 p.m. (at the Royal Infirmary) Dr. John Henderson: Medical Cases.

MANCHESTER ROYAL INFIRMARY.

Tuesday, Nov. 8th.—4.15 p.m., Dr. D. Dougal: Pregnancy in Relation to General Diseases.

Friday.—4.15 p.m., Mr. W. R. Douglas: Demonstration Surgical Cases.

Births, Marriages, and Deaths

BIRTHS

Grant.—On Oct. 27th, 1932, at the Mothers' Hospital, Lowe, Clapton-road, to Florence Margaret Grant (née Gamble) M.D., M.R.C.P., wife of Arthur Stanley Grant, of 306, St. James-court, Buckingham Gate, S.W.1—a son.

MARRIAGES

Tuckett—Thompson.—On Oct. 22nd, 1932, at Cobham, Cedric Ivor Tuckett, M.Chir., to Lettice Charlotte, younger daughter of Mr. and Mrs. W. Graham Thompson.

DEATHS

Black.—On Oct. 25th, at a nursing home, Tunbridge Wells, Dr. Arthur Campbell Black, aged 66.

Fergus.—On Oct. 24th, suddenly, at Ferncrag, Rothesay, Andrew Freeland Fergus, M.D., LL.D., F.R.F.P.S. Glasg., eldest son of the late Andrew Fergus, M.D., M.R.C.S. in his seventy-fifth year.

McGavin.—On Oct. 31st, at Folkestone, Lawrie Hugh McGavin, 63.

Nicholson.—At Ryde, Thom M.B., &c., in his seventy-first year.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS

Ottawa Agreements Bill

On Thursday, Oct. 27th, the Ottawa Agreements Bill was read a second time in the House of Commons by 423 votes to 77.

Ottawa and Cod-liver Oil

On Monday, Oct. 31st, the House of Commons considered in Committee the Ottawa Agreements Bill. Sir Dennis Herbert, Chairman of Committees, was in the chair.

Mr. George Hall moved an amendment to exclude cod-liver oil, castor oil, cocoanut oil, and certain other oils from the scheduled duties. He said that cod-liver oil was in use in almost every working-class household in this country, especially where there were young children, and local authorities spent considerable sums in purchasing bulk supplies for hospitals and sanatoria. Those authorities were concerned as to the increase in price which would result from this new imposition, and they considered that they ought not to be asked to pay an increased price for this commodity for the purpose of encouraging the cod fishing and cod-liver oil industry in Newfoundland. The Opposition would take every possible opportunity of doing their utmost to prevent the enforcement of this duty, which might be described as an imposition on the invalid and the cripple.

Mr. Mallalieu, in supporting the amendment, said he associated himself with everything that Mr. Hall had said on the question of a rise in the price of cod-liver oil. It was suggested that if there was any rise in price it would be insignificant. But it seemed to be quite forgotten that this was a time of falling wages, and small amounts added up considerably in the aggregate.

Mr. H. G. Williams said that they were told that Newfoundland oil was not good enough for medicinal purposes. Two or three years ago Prof. Drummond, of University College, London, and Prof. Hilditch, of the University of Liverpool, were invited by the Empire Marketing Board to make an authoritative report on supplies of cod-liver oil in the British Empire. In page 114 of that report its authors wrote as follows:—

> "At the present moment a considerable proportion of the cod-liver oil sold in this country is of relatively low medicinal value, largely because the pharmaceutical trade has a preference for the pale oils—mainly of Norwegian origin. In some cases, these oils are sold with a guarantee of vitamin activity that is virtually worthless, as the figures or 'units' given are often based on unreliable methods of testing."

This was the oil which the Liberal Party wanted people to consume. In pages 124–5 these scientific gentlemen, who had really been intimate with the subject, stated this as their conclusion:—

> "Of the oils from the important cod areas studied, those from Newfoundland were found to be of richest vitamin potency. Next in order of merit came those of Icelandic origin. The oils from Scotland were found to be intermediate in value between the rich Newfoundland oils and the much poorer class of oils of Norwegian origin."

In view of authoritative statements like that it was really time that that section of the Liberal Party which was opposing this Bill should abandon the vote-catching device of trying to terrify electors by saying that the health of their children was going to be imperilled. He really asked these gentlemen to drop this campaign, which was not creditable to a party with great traditions.

Dr. Burgin (Parliamentary Secretary to the Board of Trade), replying for the Government, said that they were passing through a period of extremely low prices, and consequently it was possible by arithmetic to make the cod-liver oil duty appear to be a very high ad valorem figure. That was quite a fallacious argument, because the existing price level was far too low. The ordinary method under which medicinal cod-liver oil was sold in a retail chemist's establishment was in an 8-ounce bottle. Taking the duty at the level proposed by the Ottawa agreements, it would work out at a penny on an 8-ounce bottle, but there was no reason why the penny on an 8-ounce bottle should be passed on to the consumer at all. Including the duty, the cost price of the oil was 4*d.* per 8-ounce bottle, and this was sold over the counter at 1s. 6*d.*

Sir S. Cripps: Will the hon. gentleman give an undertaking on behalf of the Government that steps will be taken to see that no addition to the price is made?

Dr. Burgin said that the hon. and learned gentleman knew perfectly well that he could give no such undertaking. Members of the Committee were susceptible to the arguments based on the figures he had given.

The amendment was rejected by 266 to 61—majority 205.

HOUSE OF COMMONS

WEDNESDAY, OCT. 26TH

Medical Treatment of Disabled Men

Mr. Smedley Crooke asked the Minister of Pensions whether he was aware that disabled men were being refused treatment by the Ministry for the disease which had at one time been accepted as attributable to service, and whether he would see in cases of attributable disability that treatment was at all times available for disabled men.—Major Tryon replied: Wherever it is established that the present condition of a previously accepted disability, whether attributable to or aggravated by war service, is due to such service, any special course of treatment certified to be necessary is provided.

Physically and Mentally Defective War Orphans

Mr. Smedley Crooke asked the Minister of Pensions whether he would inform the House of the number of physically or mentally defective war orphans over the age of 21 who were still receiving allowances from the Ministry of Pensions.—Major Tryon replied: The number of these cases in receipt of allowances at the end of September last was 87.

National Health Insurance

Mr. Buchanan asked the Minister of Health the names of the members of the consultative committee of approved societies which were consulted on the National Health Insurance and Contributory Pensions Act recently passed.—Mr. Shakespeare (Parliamentary Secretary to the Ministry of Health) replied: The proposals which were embodied in the recent National Health Insurance and Contributory Pensions Bill were submitted to the Consultative Council on National Health Insurance (Approved Societies Work) as a whole. The proposals were approved by the Council as a whole, and the consultation did not take the form of eliciting the views of each individual member, though all members were at liberty to express their views at the meeting when the proposals were under consideration. The proceedings of the consultative council have always been treated as confidential.

Fatal Road Accidents

Sir Bertram Falle asked the Minister of Transport what steps his department had taken since the beginning of the recess to diminish the loss of life from the total of 450, or more, persons per month arising out of road accidents.—Mr. Pybus replied: During the recess I have, in conjunction with the Home Office and the police, brought to their final stage the arrangements for a special investigation of the causes of fatal road accidents over a period long enough to give definite and reliable results. A form of return suitable for mechanical tabulation has been prepared for use by all police forces in reporting fatal accidents. I believe that by a more complete diagnosis of the causes of fatal accidents it will be possible to devise more effective methods to reduce their number.

THURSDAY, OCT. 27TH

School Meals and Unemployment Relief

Mr. Hicks asked the Minister of Labour whether he was aware that the London County Council, in assessing the means of applicants for transitional benefit, took into account the value of meals given at school to children; whether this was the usual practice of public assistance authorities; and, if so, whether this practice was approved by his department.—Sir Henry Betterton replied: I understand that regard is had to the value of these meals in the London County Council area and that this is commonly, though not universally, the practice elsewhere. As the same practice is followed by the London authority in dealing with applications for public assistance, their procedure is in conformity with the requirements of the Order in Council governing transitional payments.

Fatality in a Poor-law Institution

Mr. Pickering asked the Minister of Health whether his attention had been called to the case of Reuben Gilbert, an inmate of the Leicester poor-law institution, who died as the result of slipping on the polished floor, and to the fact that, although there had been several other fatalities previously from the same cause, the floors of the institution were still polished, in compliance with the orders of the Ministry of Health; and whether, in view of these facts, he would inquire into the matter generally and do all that was possible to remove such a danger, especially to the aged and infirm inmates.—Sir E. Hilton Young replied: This inmate was an old man, unable to get about by himself, and was at the time of the accident being assisted by an officer. The inmate did not, as I understand, blame the officer or make any complaint to the authority of the state of the floor, and it is questionable whether the accident was due to that cause. On the general question, I have not made any order on the subject, but I am advised that polished floors have advantages on medical grounds. A dangerously high polish should obviously be avoided, and I am instructing my inspectors to bring this point as occasion offers to the notice of local authorities.

Maternal Mortality

Mr. Lunn asked the Minister of Health what steps he was taking to implement the recommendations in the report of the departmental committee on maternal mortality.—Sir E. Hilton Young replied: So far as the work of local authorities is concerned, the final report of this committee confirms the recommendations made in their interim report which were communicated to those authorities, and on which action has already been taken in many districts. I have recently taken steps to secure the continuance of the system of confidential inquiries into the circumstances of maternal deaths in accordance with the recommendation of the committee, and I am considering what further action can most usefully be taken.

Health Insurance and Poor-law Assistance

Mr. Buchanan asked the Secretary for Scotland if he had made inquiries into the question of the director of public assistance in Glasgow and the public assistance committee continuing to defy the law relating to health insurance in the taking into account of the first *7s. 6d.* of health insurance benefit for poor-law purposes; and if he intended to take any action to have the law carried out.—Sir Godfrey Collins replied: The Department of Health for Scotland have made representations to the poor-law authority of Glasgow in cases where it appeared that the statutory provision referred to was not being observed. The amount of relief to be afforded in an individual case is, however, a matter for the poor-law authority, subject to the individual recipient's right of appeal on the ground of inadequate relief.

Silicosis and Asbestosis

Mr. Jamieson asked the Home Secretary the number, down to the last convenient date, of persons employed in the asbestos industry who had been medically examined in pursuance of the Silicosis and Asbestosis (Medical Arrangements) Scheme in England and Wales and Scotland, respectively; the total amount paid by employers to the Medical Expenses Fund in respect of such examinations; and the number of persons certified by the medical board as totally disabled or suspended from employment as suffering from asbestosis.—Sir J. Gilmour replied: Since June 1st, 1931, when the Silicosis and Asbestosis (Medical Arrangements) Scheme came into force, 1535 workmen have been examined under the scheme in the asbestos industry in England and Wales, and 80 in Scotland. The total amount paid by employers to the Medical Expenses Fund in respect of these examinations is £2300. Certificates of total disablement or suspension on account of asbestosis, or asbestosis accompanied by tuberculosis, have been issued in 30 cases in England and Wales, and 2 cases in Scotland.

Mr. Jamieson: In view of the large expense incurred by employers and the small number of men found to be unfit for work, will the right hon. gentleman consider rescindi or modifying this scheme?

Sir J. Gilmour: No, Sir. I think that this new experiment is fully justified. Of course, it is true that it require very expert examination, but it may be that the cost will b materially reduced in the future.

Lieut.-Commander Agnew: Is the right hon. aware that in the case of tin mining the scheme oper to the disadvantage of both employers and employees especially as the latter cannot get employment?

Sir J. Gilmour: I think it is too early to make assertion of that kind.

Defective Eyesight of Juveniles

Mr. Lovat-Fraser asked the Minister of Health if attention had been called to the report of the recent gation by the Ministry of Labour into the question unemployment among boys and girls under the age of 18 in which it was stated that the chief defect in both was poor eyesight; and if he would inquire into the cau of this evil with a view to counteracting it.—Sir E. Hilto Young replied: The report to which my hon. friend indicates the importance of the preservation of eyesigh and the prevention of blindness, and my hon. friend w be aware of the work which is already being done in direction under the maternity and child welfare and schoo medical services. The whole problem is at present the consideration of two committees, one of which appointed by the Board of Education, and I will for this report to be brought to their notice.

TUESDAY, NOV. 1ST

Outbreak of Typhoid at Malton

Mr. Turton asked the Minister of Health how many of typhoid had been discovered at Malton to date; th present condition of the patients; where these were treated; and whether the cause of the outbreak had located.—Mr. Shakespeare (Parliamentary Secretary the Ministry of Health) replied: 88 cases of typhoid are known to have occurred at Malton up to and Oct. 30th. My right hon. friend is unable to say any about the condition of individual patients, except tha three of the patients have died. Patients are being in the fever hospitals at York and Driffield and in cottage hospital at Malton, which has been appropriated for the purpose. As my right hon. frien is at present advised, the infection appears to have be water-borne, but he will communicate further with my friend when he has received the report of his medical who has been investigating the outbreak.

Clapham Maternity Training Hospital

Mr. Denville asked the Minister of Health if any tests were imposed on pupils who were training in Clapham Maternity Training Hospital.—Mr. Shakespe replied: My right hon. friend has no information on point raised by my hon. friend. I should perhaps add my right hon. friend's concern is solely with the effic of the training given in such an institution.

THE SERVICES

ROYAL ARMY MEDICAL CORPS

Lt.-Col. E. H. M. Moore, having attained the age compulsory retirement, is placed on retd. pay.

Maj. A. L. Stevenson to be Lt.-Col.

TERRITORIAL ARMY

Capt. D. Lamont resigns his commn.

Lt. J. Wright to be Capt.

TERRITORIAL ARMY RESERVE OF OFFICERS

Lt.-Col. C. H. J. Fagan and Majs. C. E. K. Herapath and J. C. Marklove, having attained the age limit, relinquish their commns. and retain their rank.

Maj. A. S. Hebblethwaite, from the Active List, to be Maj.

Capt. D. E. Core, having attained the age limit, relinquishes his commn. and retains his rank.

INDIAN MEDICAL SERVICE

Col. E. A. Walker to be Maj.-Gen.

Lt.-Col. E. W. C. Bradfield to be Col.

Lt. (on prob.) D. P. Mitra to be Capt. (on prob.).

Surg. Lt.-Comdr. E. O'Reilly and Capt. J. S. B. Forde to be Capts. (on prob.).

J. W. Bowden and W. Mackie to be Lts. (on prob.).

Maj.-Gen. C. Hudson retires.

Capt. A. K. Menon relinquishes his temp. commn.

NOTES, COMMENTS, AND ABSTRACTS

MENTAL AFTER-CARE

A MEETING of the Mental After-Care Association was held at Springfield Mental Hospital on Oct. 25th, the chair being taken by the President, Lord WAKEFIELD OF HYTHE, who emphasised the fact that the work of the Association was one of salvation, not salvage, since mental disease was curable. The most important thing about the treatment of mental illness was its increasing success. He appealed for funds, and supported his own appeal by wiping off the overdraft of £579. After the Dean of WESTMINSTER had spoken in moving terms of the religious aspect of the work, Miss RUTH DARWIN described after-care work in America. In America there was a readiness to recognise mental illness and no tendency to regard it as a bugbear. People were much more prompt in seeking advice, and young social and medical workers were keen to work on the mental health side. Inevitably this attitude was associated with much superficial psychological talk and with too great eagerness to run to a psychiatric out-patient clinic with the children. In New York State there was a hospital for 6000 mental patients and a new one for 10,000 was being built. There was also a special bureau for social work in the 20 mental hospitals of the State. As a general rule one social worker was added for every hundred patients on parole. Five main aims could be distinguished: (1) to help the doctor in diagnosis and treatment by providing information; (2) to help the patient by coming directly into touch with the home surroundings, and by doing things that had been left undone because of a sudden departure; (3) to help the family to understand what the mental illness of the patient had meant and to wipe out soreness, anger, and irritation; (4) to prepare the way for the patient's return; (5) to help the patient to remain out when once out on parole or recovered. The number of patients able to go out and the length of time they stayed out depended very largely on the number and skill of the social workers.

Attached to the hospitals were community clinics, which met periodically. Here cases were referred from the courts and schools. In the hospital itself was a social service office where all cases were registered, and a central exchange bureau in New York supplied information about the families. The social worker saw each patient in the ward and paid a home visit, and further visits were paid as required. The office was always open on Sundays, as that was the day on which the relatives most often called. One medical officer was in charge of the parole patients who had to report month by month at a clinic. The social workers acted as technical assistants to the doctors attending the medical case conferences. The work was thorough and well organised, and yet was done without over-elaboration of reports in psychological detail. The workers were paid members of the staff and were highly trained. The correlation of knowledge of the home with knowledge of the patient in hospital was a great asset. The work of the Mental After-Care Association had been studied by American visitors before the work over there had been initiated. The need for such work was great and was not only a question of common humanity, but also of common sense.

AFTER-CARE IN LONDON

Mr. E. J. SAINSBURY (chairman of the L.C.C. Mental Hospitals Committee) spoke with high appreciation of the work of the Association. During its 40 years of life, he said, it had extended in every possible way, both in magnitude and in character. In every L.C.C. mental hospital it was called on for a report of home conditions which were of vital importance to the welfare of patients released on trial or discharged. It was useless to send a patient back to a home which would involve him or her in such stress that another collapse was inevitable. No official inquiry could reach the depths plumbed by the Association's workers, and he hoped the time would never come when the L.C.C. would set up a department to take over the work. To have it said by a neighbour, "I saw the County Council inspector at your house yesterday," was to damn the whole effort to help. When there were no friends to help or home fit to go to, the Association stepped in again with its convalescent hospitals. The Association acted as the County Council's almoners and often had to incur additional expenses—a difficulty which the L.C.C. was trying to meet. Patients on trial were visited at home and reports on progress and advice were sent to the authority, the advice invariably being accepted and that over very long periods. The work was of the utmost value to the London County Council. Now that voluntary patients could be received, the Association were taking these cases under the same conditions as they took certified ones. It was in the early stages that the greatest care was required and clinics had been set up throughout London. In these also the Association helped. During the first six months of 1932, preliminary inquiries had been made by the Association in 526 cases; 117 patients had been received into hostels, work had been found for 35 discharged patients, and another 127 had been helped in various ways. In addition, 21 voluntary cases had been taken into hostels, work had been found for 8, and 22 others had been helped. The total was nearly 900 for the six months. Mr. Sainsbury concluded with one or two "human documents" to illustrate the work which was so greatly valued by his Council. He was most grateful of all, he said, for the succour given to young girls who were homeless and friendless.

Mr. C. L. DE SALIS (chairman of the Springfield Mental Hospital Committee) welcomed the Association to Springfield, and said that in Middlesex also they found the Association most helpful. Its good offices were being used more and more, and especially in connexion with the out-patient clinics. Many patients could be sent to hostels from these clinics instead of to mental hospitals. The accounts were in rather a gloomy state; a great deal of money must be provided by voluntary contributions if the work was to go on and to increase. He hoped that the work would always be on a voluntary basis, and that it would never become officialised. People seemed to be far readier to help hospitals than to help after-care. There should be a representative of the Association in every parish, for people must be educated to the fact that mental disease was curable.

Dr. REGINALD WORTH (medical superintendent, Springfield Mental Hospital, and chairman of the Association), in thanking the chairman and speakers, emphasised the voluntary standing of the Association.

FUTURE OF HYGIENE IN THE FAR EAST

IN his Chadwick lecture, delivered in London on Tuesday last, Prof. Kielstra, of Leiden, said that the old theory that "the native is crusted with prejudice" could no longer be regarded as a sufficient explanation of his aversion and indifference to modern hygienic and medical treatment. More thorough investigation showed that these attitudes should be considered in relation to the thought-structure of the indigenous population, the base of which was animistic even where Islam prevailed. Animism by its nature was conservative; therefore hygienic measures met with opposition, except when the fear of an immediate danger as from cholera or small-pox kept it down, or where the native's mind was made accessible to new ideas. In this connexion he greatly praised the work of the missionary societies. Prof. Kielstra unfolded how modern colonisation itself paves the way for new ideas, since it cannot abstain from measures which influence native society and force its members to adjust their attitude. Moreover, it was sufficiently proved, he said, that when the influence of the indigenous society was eliminated—as, for instance, in the army or among the Javanese labourers on the estates in Sumatra—hygienic results could be obtained as in any western society. In his opinion the public health service should confine its work to general hygienic measures—such as the draining of swamps, the regulating of rivers, and the improvement of housing conditions—until ethnological and social observations showed that the indigenous population was ripe for more individual medical treatment.

THE HOSPITAL ALMONER

A STUDY of hospital social services in England has been published by the Committee of the Hospital Almoners' Association and is obtainable at the Institute of Hospital Almoners, Tavistock House, W.C.1, for 2*s*. It is dedicated to Sir Charles Loch, to whose intimate study of the working of out-patient departments of the London hospitals the foundation of the office of hospital almoner is due. The pamphlet deals briefly with the development of the British hospital system and the early days of almoners' work. The present duties of the hospital almoner are discussed in more detail—her social work, practical problems connected with institutional and convalescent treatment, procuring instruments and surgical appliances for patients, arranging for special diets and extra nourishment and rest, and for the care of chronic and incurable cases, and of those who are cripples or mentally subnormal. Social work in municipal hospitals, the prevention of hospital abuse, the assessment and collection of patients' donations, coöperation with other workers and other funds, and follow-up work are also discussed. More specialised almoners' work, such as work in venereal disease, maternity, and ophthalmic departments are indicated. An interesting chapter is that describing a typical day in an almoner's life. In a future edition it may be hoped that the conditions of entry to this comparatively new profession and some account of the course of training provided will be included.

THE MECHANISM OF HYPNOTISM

Two little brochures [1] recently published deal with hypnotic suggestion on somewhat the same lines. Dr. Cannon concentrates on the stages of induction and the physiological state that supervenes. He describes very fully the various methods used; but is frankly most interested in the neurology of the condition. Mr. Metcalf is more psychological, and even gives Freud's interpretation of the state of hypnosis—i.e., its relationship to transference and the libidinal rapport between subject and physician. He discusses the relation of hypnosis and suggestion to Christian science and religious healing in general, and writes discursively on spiritism. Clinicians might profitably read this book, since the influence of suggestion and the unconscious application of psychotherapy are far more potent factors in their daily work than most of them realise even to-day.

ZEBE-À-PIQUE

VEGETABLE extracts have some vogue in West Indian islands as malaricides. One of these is zebe-à-pique, which is the local name for the bastard cedar bush (*Parphenium hysterophorum*) commonly distributed over the island of Grenada. A favourite method of preparing the extract from the leaves is to place three or four in a bottle of vermouth, brandy, or whisky until the infusion is very bitter. Incidental to a malaria survey of the island under the auspices of the international health division of the Rockefeller Foundation, an examination of the efficacy of this reported remedy was made by Dr. J. Andrews,[1] assisted by the staff of the colony hospital at St. George's. Varying doses from one tablespoonful to a wineglassful were given with meals three times a day. In all, 12 individuals suffering from the clinical manifestations of malaria, in whose blood subtertian malaria parasites were demonstrable, were placed under observation. Of these, one half (six) received normal quinine therapy whilst the remainder received the nostrum. No proof could be obtained of any specific action. Dr. Andrews concludes that if zebe-à-pique does have any malaricidal properties they are not comparable with those of quinine.

ABSORPTION OF OXYGEN FROM THE SUBCUTANEOUS TISSUES

OXYGEN is sometimes administered subcutaneously for therapeutic purposes, and an attempt has lately been made by Indeyit Singh,[2] of Rangoon, to find how fast it is absorbed from the tissues. Decapitated cats were used in the experiments, and preliminary observations on oxygen intake were made to see whether metabolism was constant or whether it was declining regularly—in which case corrections had to be made. The concentration of oxygen in the inspired air was maintained at a constant level, and after the preliminary estimations oxygen was injected subcutaneously at one, two, three, or four places; it spread, as a rule, over more than half the total subcutaneous area if four punctures were made. The rate of consumption of oxygen was observed at half-hourly intervals, and the investigator found that absorption from the subcutaneous tissues was very slow; it varied from 0·6 to 1·2 c.cm. per minute when 500 c.cm. were injected. An hour, or an hour and a half, after injection absorption almost ceases, owing to the lowering of oxygen tension by the diffusion of carbon dioxide and nitrogen from the tissues.

It is concluded from these experiments that the efficiency of the lungs in saturating the blood with oxygen is 15 to 20 times greater than that of the whole subcutaneous region.

LONDON MEDICAL EXHIBITION.—The Wilson Rubber Company, Ltd. (Slough, Bucks), ask us to point out that no foreign labour is now employed in their factory.

LONDON MEDICAL SOCIETIES

LAST week we gave a list of officers of London medical societies during the present session. The following particulars may be added to those already published:—

Hampstead Medical Society.—President: Dr. Herbert Dixon; Hon. Secretaries: Dr. G. B. McCaul and Dr. David Gillespie. Address: 248, Finchley-road, N.W.3.

London Jewish Hospital Medical Society.—President: Mr. Harold Kisch, F.R.C.S.; Hon. Clinical Secretary: Dr. David Krestin. Hon. General Secretary: Dr. L. Phillips. Address: London Jewish Hospital, Stepney Green, E.1.

North London Medical and Chirurgical Society.—President: Dr. P. O. Ellison; Hon. Secretaries: Dr. W. E. Snell and Dr. Kathleen Matthews. Address: Royal Northern Hospital, Holloway-road, N.7.

Priory Medical Society.—Hon. Secretary: Dr. John Reid. Address: Thornton House, The Avenue, N.W.6.

ADDRESSES AND ORIGINAL ARTICLES

SUGGESTION, HYPNOTISM, AND THE WILL *

By WILLIAM BROWN, D.M. OXF., D.Sc., F.R.C.P.LOND.

WILDE READER IN MENTAL PHILOSOPHY IN THE UNIVERSITY OF OXFORD; HON. CONSULTING PSYCHOLOGIST AND DIRECTOR OF THE PSYCHOLOGICAL LABORATORY, BETHLEM ROYAL HOSPITAL

MODERN investigations of the phenomena of suggestion and auto-suggestion are throwing further light upon the nature of the will. In suggestion as ordinarily understood the mind is regarded as in a momentary state under the driving force of ideo-motor action. An idea, an impression, a thought, is in the mind, and that thought tends to pass over into action. Indeed, Pierre Janet's theory is that in suggestion an idea produces its maximum effect, and conditions favourable to suggestion do tend to produce the maximum effect, keeping other considerations—competing considerations—in abeyance. In ordinary normal mental life idea follows idea, and you have a train of mental activity going on, as it were, on the surface of the mind, and any particular idea is not given time to produce its maximum effect, but is quickly replaced by another. But in formal suggestion treatment, what is aimed at is to give this idea its full chance to express itself to the fullest possible extent. So suggestions of muscular power take effect as long as ideas of muscular feebleness, difficulties, and doubts are kept in abeyance. The idea of a sensory experience, such as a feeling of heat or pain, can be intensified and allowed to produce its full effect. An idea of a burn or blister will actually raise a blister in a hypnotised patient where competing ideas are kept away. Ideas are not mere ideas, they are also forces. They carry with them not only a cognitive aspect but also a conative aspect, an aspect of striving, a tendency to bring about some change in the outer world or in the inner world. In suggestion an idea is given an opportunity of developing itself to its full extent. That is one way of thinking of suggestion.

Suggestion and the Subconscious

Prof. W. McDougall defines suggestion as the acceptance of an idea independently of logically adequate grounds for such acceptance. A subject of successful suggestion treatment accepts what is said to him independently of logically adequate grounds. But here the word acceptance can have more than one meaning. The individual may consciously accept and nothing may happen. Conversely an individual may consciously reject or doubt and yet something may happen. The acceptance of the idea depends on the condition of another part of the mind than the conscious mind—viz., on the condition of the subconscious mind, the background of the mind. That again is merely a popular term. The subconscious is the sum total or system of fundamental tendencies, urges, instincts, interests, which the individual has inherited from previous generations, and others which he has developed on the basis of his earlier inherited instincts. All these are of importance to him. In his conscious mind he may not have a clear and adequate view of what are the most important urges of his life. Consciously he may attach himself to certain aspects of existence, certain desires and wishes, whereas the desires and wishes that are fundamentally more important and move him more are hidden (more or less) in the subconscious. Suggestion appeals to these subconscious wishes and desires, and the realisation of suggestion is the realisation or modification of such wishes and desires. Hence the surprising results which may sometimes occur in hypnotic suggestion. Certain suggestions may be hardly accepted at all, hardly reacted to, although the person seems to have obvious reasons for responding. Other suggestions may be accepted, although there is no obvious reason in consciousness why they should be. This is specially the case with regard to pathogenic or bad suggestion. A person does not consciously wish to be ill. He consciously fears illness. Nevertheless he may have a subconscious desire for illness because of a craving for sympathy or for power over relatives, or to preserve his self-respect in the face of apparently insurmountable difficulty. He may cut these fears out of his conscious mind and yet retain them in full force in his subconscious. There are two general forms of fearlessness: the fearlessness of the individual who has faced the ordinary possibilities of danger and has recognised once and for all that fear is no good and gives it up, and that of an individual who finds the experience of fear a painful process, and so turns away from it but does not really face the matter, and then can be easily taken off his guard, and subconscious fear may surge up or may manifest itself in consciousness in distorted ways. Fear is an important factor in the working of suggestion even on the fully conscious level, but it is very much more important when working on the subconscious level.

Suggestion, Instinct, and Emotion

Nevertheless it is not only fear and desire that may explain the realisation of suggestion, but the working of every fundamental instinct. There is not a primary instinct that does not bring its own suggestive tendency. Self-assertion, self-abasement, gregariousness, curiosity, whatever it may be, brings its own suggestion. The secondary emotional tendencies also bring suggestion. Jealousy, which may or may not be a primary emotion, brings its own system of suggestion. A person under the influence of jealousy is ready to believe statements about a rival which he would not believe if he had a completely clear and rational view of the situation. Baudouin has put the matter in the following way. He regards emotion as an auxiliary factor, a factor that helps suggestion. This statement needs qualification and correction. The truth is, firstly, that the instinctive tendency underlying the emotion is in some cases the driving force of suggestion; and secondly, that the emotion is often a sign of conflict, of a lack of unity of the mind. The mind is not at one with itself, and in this condition suggestion is more likely to be accepted. For in these cases emotion is not so much cause as effect. Emotion is a sign that the person is not in harmony with himself, and can be taken off his guard, and thus become the victim of suggestion. He cannot marshal his intellectual powers and ideas, to bring them to bear on the situation. He has been carried away by the suggestion before he has really begun to think about the matter.

Suggestion and Volition: the Law of Reversed Effort

Then the problem of suggestion impinges upon the problem of will, in the facts under the general "law

---

* Paper read to Section J (Psychology) of the British Association for the Advancement of Science at York on Sept. 2nd.

of reversed effort." The facts had long been recognised, but Coué was the first to summarise them in a paradoxical and challenging way. "Where the will and the imagination are in conflict," he says, "the imagination always wins." And he identified imagination with suggestion. In his little book, "La Maîtrise de Soi-même," the word imagination in French is interchangeable with suggestion. He puts suggestion or imagination higher than will. One feels there must be some error here, because according to any systematic theory of psychology, will is the highest form of mental activity. Will indeed is the entire mind in action in its unity—so far as at any moment it is a unity—it is the character fully expressing itself. If the character only partially expresses itself, the man's actions may not be entirely in harmony with his character. If the other sides of the character show themselves later the person may feel remorse or regret. He would not feel this if his mind had previously been acting in its entirety.

How are we to explain the law of reversed effort? Let us take examples. (1) A desire to remember a proper name. We are unable to do so; we make an effort, and we find that the more effort we make the less we succeed. Whereas before, the name was "on the tip of the tongue," it now seems entirely to retreat, and leaves no sign in consciousness. On the other hand, if, instead of willing and making an effort, we calmly think to ourselves that the name will come to us presently and that we will not bother about it, we find that it does come. Or (2) when we are learning to ride a bicycle, if we see a stone in the road, and become alarmed and make an anxious effort to avoid it, there is a tendency for the bicycle to make a bee-line for the stone. On the other hand, if we keep calm and cool, and simply affirm to ourselves that we are going to avoid the stone, we do avoid it. In the effort to remember the name or avoid the stone, have we will? We have desire and wish—a wish that is spasmodic, that is violent, but we cannot say that with our whole mind we have willed to avoid the stone or remember the name, because will in its complete form carries with it *belief that we shall succeed.* That is why, as Aristotle said, we cannot will the impossible. We can will what we believe to be possible, although it actually is impossible, and then we fail. Where we know that the result is impossible we cannot will. In the case of the forgotten name there is a fear of failure checking and preventing us from reaching the complete stage of will. If we can reach the complete stage of will, believing that we are going to remember the name, that will produce the maximum effect. But in the condition of effortful wish, the spasmodic effort arouses and intensifies the fear of failure, which prevents the belief in success. Belief in the possibilities of success, the essential constituent of will, is absent. You have wish instead of will. You have suggestion accompanied by fear of failure, based upon the fear instinct or the danger instinct. And against that you can only put the desire to succeed, unaccompanied by any special emotion. This is put against the idea of failure, accompanied by fear of failure, which is what Coué means by the imagination.

There is really a conflict between two imaginations—the imagination of success and the imagination of failure. The imagination of failure is accompanied by a feeling of fear. There is no real conflict between will and suggestion, but a conflict between one suggestion and another suggestion. The state is a state of incomplete will. Coué was quite right in his practical conclusion that in order to get the maximum effect of suggestion treatment, patients should avoid effort, because effort tends to bring with it the idea of failure and fear of failure, and tends to neutralis any effort towards success. Our deepened of suggestion derived from its use in psychotherap has deepened our insight into the nature of the We still hold that any patient suffering from psy neurosis suffers from defective will. He needs to b helped to achieve complete volition. In directions a patient is unable to will; if he tries t will, the law of reversed effort comes in.

A typical example is agoraphobia; a p suffering from fear of open spaces cannot walk dow the street or cross the street, becomes more and m panicky and nervous, and has to return home. An the more he tries the less he succeeds. It is n that his will is failing, but that he has not reall completed the act of will in this respect, that he unable to walk down a street alone and unable reach that state of will which involves calm in success. A feeling of certainty is absent. Why The reason can only be discovered by deeper anal going over the patient's past life and seeing how agoraphobia set in. The memories and tenden of those early experiences are of importance to patient and to the doctor who wishes to cure him. The doctor helps him to will, to be capable of compl volition. In this volition, apart from analysis, it necessary to get rid of spasmodic effort, spasmodic effort brings fear of failure. If encourage the patient to get rid of his fears, to calm, he will be more successful. And the way which you give the patient advice is to encourage to make the affirmation with confidence, with that he is going to succeed. If the patient himself down and says, "I am going to manage it, he is more likely to succeed. He has to attack source of the fear by analysis, but suggestion tre ment will help him to reduce the fear to a when it does tend to rise.

In a way suggestion treatment is a of the will, or a help towards the completion of the will The complete will carries with it the suggestion success, an adequate control of the imagination The individual has to train himself to imagine success. It is important, not only for psychoneurotic patient but for all of us, to train our imagination in this matter. That is why I am so emphatic that fea should be denied, should be turned away from, and in its place should be put confidence, and one sh make affirmation to one's self that whatever happen one is not going to be afraid or disturbed. This i more than the spirit of stoicism. The spirit of stoicism is that evil, though inevitable, should be bravely borne, but in this attitude of mind you go further and "deny" evil. Having taken whatever steps are necessary to avoid danger, you refuse to let the thought of danger play upon you subjectively and lower your vitality by raising a feeling of fear. Likewise with lesser dangers and difficulties, there should be control of the imagination so that the mind is as active as it possibly can be in its unity.

Auto-suggestion for the Normal Person

I should like here to emphasise the value and importance of formal suggestion and auto-suggestion for the *normal* person as a means of increasing his mental power in various directions. If he makes calm affirmations to himself while lying on a couch in a state of mental and muscular relaxation, such affirmations may be realised by subconscious mental activity and in this way he may improve his powers of mental concentration, his memory, and his mental aptitude along special lines. He may also correct bad habits and increase self-confidence and self-control.

Often suggestion treatment from another person is needed to give him a start, and then he can carry on by himself. The method acts by releasing mental tension and removing subconscious dead-locks and inhibitions, encouraging spontaneity and self-realisation. Above all it neutralises subconscious doubts and fears, and clears the way for the creative process that wells up from the depths of the mind. Thus it can revive failing inspiration in the realm of music and of the other arts, and can enable a discouraged person to believe in himself once more. By facilitating the imagination of success, and by giving precision and control in imagination, it contributes powerfully to adequate and complete volition in any special direction. Perseverance in the practice of auto-suggestion may sometimes transform a person's temperament and change him, for instance, from a worrying and self-tormenting hypochondriac into a man of calm tenacity of purpose and serene self-confidence.

Personality and the Will

This brings one to the question of personality. When considering the question of will, the question of personality is not far behind. It is the same problem looked at from a different point of view. When we speak of the will we think of the momentary reaction of the mind to a particular situation; when we think of the character, we think of the totality of the mind expressing itself in the will. We are at once faced with the problem of multiple personality, and our best way of dealing with that problem is to avoid rushing to extreme cases of multiple personality and drawing premature conclusions from them, but to consider closely the variations of the so-called normal mind.

In the normal mind there is a tendency to alternation of mood and to multiplicity of ideals. Individuals have more than one ideal of themselves. Especially as children do they find from day to day and from week to week that they have different ideas as to what they would like to be, which are mutually exclusive. So the mind oscillates from day to day, and gradually settles down as one gets older under the pressure of circumstances, and a sort of natural selection goes on. Certain ideals are stamped out under the cruel influence of circumstances. The individual throws himself more and more into the following up of one ideal. But nevertheless he has to meet different types of people with different interests and ideals, and we find that he responds to them in different ways. He is certainly a different kind of person in one general environment from what he is in another. His business self is different from his social self, and both differ from his religious self. With every single person he meets he is slightly different. He does not show the same side of himself to different people. These different aspects are, in a way, subsidiary selves and one can be encouraged at the expense of others.

Besides that there is a more fundamental unification, the more fundamental self, of which these are manifestations. The question is whether that more fundamental self is something existing at the beginning and continuously present and active through life, or something that is gradually being developed. From the purely scientific point of view there is much to be said for the theory of development, that the personality is created partly through identification with different types of people who call out admiration, and partly under the impetus of innate tendencies. Besides that there is the work of reason, which is of great importance. The individual learns from experience, and knows that if he follows up certain spontaneous fundamental tendencies he suffers for it; he is unhappy and makes other people unhappy. Besides this he gets a feeling of lowered worth..

Here we must admit an intuitional element. We must assume that the individual comes into the world with the power of discovering values through intuition or direct insight. Just as he can discriminate values in beauty, truth, and goodness, so he can discriminate values as regards personal activities. This power is to a certain degree a power of creation. The mind pushes forward, develops out of the primitive levels, the earlier stages of evolution, and is continually pushing forward, and it is reminded of this especially when it fails, when there is regression. And of course in wrong-doing there always is such regression. But especially in pathological cases, in nervous illness, is there a regression, and the symptoms are signs of such regression. The mind is failing in some directions to proceed, and is retreating from reality. And in order to save itself from the realisation of this retreat it becomes definitely ill.

Illness is a piece of apparent bad fortune that prevents the mind from understanding the true situation and relieves it of the responsibility of failure. In treatment therefore we have to encourage the patient to face the situation more fully, and to be ready to accept responsibility once more. But I admit that this is a hard saying and in some cases really too hard. Often the illness is the result of failure to deal with responsibility almost too heavy for the individual's shoulders, and the main burden of responsibility should be placed not on the individual but on society. There is such a thing as collective responsibility, and in many cases the responsibility for the failure of some particular individual may be more the responsibility of the people around him. Where a person has become psychoneurotic through unfortunate experiences in early life, the responsibility rests on the shoulders of those who should have protected the child from such experiences, rather than on the child itself.

We find that just as auto-suggestion strengthens the will, because it gives the patient the opportunity of controlling his imagination, so analysis is an indirect means of training the will. Through analysis the individual is relieved from false personality, from undesirable influences of early life, undesirable identifications, &c., that have taken place. As the patient reviews his past life, as these influences come up, he sees them for what they are and can simultaneously free himself from them. He realises how much was just childish imitation. He can bring reason to bear and later experiences to bear, and see things in their true proportion, and so judge their value more truly.

Multiple Personality

Finally we have to decide about the more extreme cases of multiple personality. We must bear in mind the possibility that they are artificially produced or intensified through the hypnotic methods employed in investigating them. They are small in number, few and far between. One does not question the bona fides or genuineness of the scientists, many of them of high standing, who have reported such cases, but it is possible that in trying to describe the cases they may have made the facts too clear-cut. An investigator of such experience in these matters as Dr. Morton Prince has emphasised his belief that multiple personality is not a denial of the unity of the mind. These persons are one, and only many in the sense that they are one. These other personalities of theirs are aspects of the one personality. The main reason for the limited aspect of the subsidiary personality is a breaking across of the memory continuum. But that is not the only characteristic. You seem to have a dissociation not only of past memories, but also of instinctive dispositions, and this shows itself in a selective influence over the memories. Certain sets of memories are controlled by the self-assertive instinct, others by the instinct of self-abasement, and so may arise an alternation of a depressed with an elated personality.

The cause of dissociation may be physiological and ultimately physical. It may be that through fatigue toxins are produced which paralyse some of the synapses of the higher levels of the nervous system, so that you get a dissociation on the cerebral side, and the brain cannot function as a unity. So with rest and physical treatment these patients may gradually recover. On the mental side, too, there is incompatibility of thought, mental conflict, a deadlock, and one side or the other has to give way.

The Psychology of Conversion

It is in such a mental situation as this that the phenomenon of conversion may occur. In conversion you have a change of heart and mind, almost a new birth, the appearance apparently of a new person. Probably in its true form it is a process of growth. There has been a certain incubation period during which ideas have been maturing—a new outlook has been maturing—but it does not come into consciousness until a later stage of development is reached, and the person looks back on his past self as dead. He rises on stepping-stones of his dead selves. Indeed it is possible that this is really the most accurate way in which we can describe the development of the mind. We hold certain general ideas which must later on be superseded, we pass from ideal to ideal, and as we near the achievement of some ideal we realise its weakness and shortcomings, and a new ideal, a further prospect has been opened to us. "New occasions teach new duties." That may come sometimes very suddenly in the form of a conversion experience. In religious psychology conversion is best defined as a turning away from a merely naturalistic outlook on life to a more spiritual outlook, a turning from the temporal to the eternal, a realisation that there is an eternal aspect of life where one may be spiritually secure independently of whatever misfortune may befall one. The personality suddenly recrystallises into a new mental attitude with an altered scale of values, and with renewed energy and inspiration, and a deepened insight into the meaning of existence.

SURGERY OF THE BLOOD-VESSELS*

By Sir William Wheeler, M.D. Dub.,
Hon. F.A.C.S.

HON. SURGEON TO THE SOUTHEND GENERAL HOSPITAL; PAST PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS IN IRELAND

Those who have paid homage to Murphy at these great assemblies in past years have alluded specifically to some branch of his work, and some have recorded their own experiences in surgery in order to emphasise their indebtness to his teaching. The scope of Murphy's writings is so wide that each successive speaker has been able to find a path which covers new ground. By referring to individual and detached cases I will endeavour in small measure to follow this precedent, and I propose to begin by speaking of the surgery of the blood-vessels.

This branch of surgery became a favourite subject of research and of practice during the opening years of the last century.[1] The teaching of John Hunter was carried across the Atlantic by Wright Post to New York, by Physick to Philadelphia, by Gibson to Baltimore, and by Warren to Boston. One surgeon alone, Valentine Mott, ligatured the common carotid 43 times, the external carotid once, the first part of the subclavian once, and the third part of the subclavian four times. It is no matter of surprise, says D'Arcy Power, that the tradition of the surgery of the blood-vessels is stronger in the United States than it is in this country. Prof. Rudolph Matas has notably maintained the tradition at New Orleans by his reparative treatment of aneurysm which is based upon experimental surgery in the true Hunterian spirit.

Murphy was at home in the realm of vascular surgery. In the year 1896 he performed the first recorded end-to-end suture of a divided artery. His description of how he approached a false aneurysm of the axillary artery by division of the clavicle and ligature of the subclavian artery is a noteworthy contribution to his surgical records. He paints a dramatic picture of a case of aneurysm of the internal carotid artery mistaken for a tonsillar abscess. Then comes the mention of 13 different forms of treatment for aneurysm, and finally the statement that no surgeon should start the active practice of surgery until he has done a considerable amount of experimental work on the arteries and veins of dogs.

LIGATURE OF THE INNOMINATE ARTERY FOR RIGHT SUBCLAVIAN ANEURYSM

In May last I ligatured the innominate artery for aneurysm of the subclavian artery involving the first and second stage.

The patient was wounded in 1915; pieces of shrapnel were shown by X rays, scattered in the region of the right shoulder-joint, and portion of a bullet could be felt to the right of the suprasternal notch under the insertion of the sternomastoid muscle. The wall of the artery was apparently injured, but the aneurysm did not become evident until 1928, 13 years after the wound. It steadlily increased in size until the swelling above the clavicle reached the size of a duck's egg. The right recurrent laryngeal nerve was paralysed. The radial pulse was not affected, the blood pressure was the same on both sides. The X rays demonstrated some calcification within the sac. The Wassermann reaction was negative.

In some respects this tumour was not typical of aneurysm; there was no bruit, expansile pulsation could not be detected; there was no difference in the carotid or radial pulses when compared with those of the other side. The operation was designed to ligature the subclavian artery behind the scalenus anticus muscle at the commencement of the second stage.

The middle portion of the clavicle was turned downwards on the chest with its pectoral attachments. The aneurysm was laid bare and the bullet was removed. The external and internal jugular veins were found obstructed and distended. The supraclavicular and transversalis colli arteries spread transversely across the upper portion of the tumour. The scalenus anticus muscle had disappeared and the phrenic nerve was not located. It was soon seen that the sac extended to the bifurcation of the innominate artery, and that ligature of the subclavian vessel was impossible. It was obvious that without further removal of bone the innominate artery could not be exposed behind the sterno-clavicular articulation without the rough handling of the aneurysm, which had led to disaster in many recorded cases. With chisel and mallet, the inner end of the clavicle together with the right half of the manubrium sterni (leaving the sternoclavicular joint intact) were separated and retracted ards and to the left. The innominate artery was now alised in its entire length. The innominate veins were seen; the pleura caused no embarrassment, the nerves ained hidden.

---

* Abridged from part of the J. B. Murphy oration delivered before the annual clinical congress of the *American College of Surgeons* at St. Louis on Oct 17th.

wo ligatures of No. 2 chromicised catgut were passed d the artery distal to the thyroidea ima branch. They e gradually tightened, taking care not to cut through inner coats of the vessel. Pulsation at once ceased in aneurysm and the radial pulse disappeared. Proximal he ligature each pulsation appeared like a sledge-hammer v upon the occluded portion. It looked as if the assault ld not be resisted. For this reason an additional single ture of catgut was placed round the artery near its origin n the aorta. The thyroidea ima was ligatured with fine . The divided portions of the sternum and clavicle e replaced in position and held by catgut passed through l holes. Recovery was uneventful but for some downward placement of the divided portion of the clavicle. In three s the radial pulse reappeared and within a week it was l and synchronous with the pulse on the opposite side. ur months after the operation the aneurysm had npletely disappeared.

The lesson learnt from this case was that ligature the innominate artery was not a difficult operation ovided the old inadequate methods of approach ere abandoned. Six weeks after ligature some slight lsation could be felt in the aneurysm, but otherwise e cure appeared complete.

Up to and including the year 1922, according to allance,[2] there had been 57 ligatures of the innominate rtery, with 19 recoveries.

A case of ligature of the innominate artery was exhibited y Mr. Coppinger, of the Mater Hospital, Dublin, at the ection of Surgery of the Royal Academy of Medicine in reland on Feb. 24th, 1893. The record states that this as the first successful case of ligature of the innominate rtery ever exhibited at any medical society in Europe.

The ideal operation for subclavian aneurysm is xcision of the sac after proximal and distal ligature. This has been successfully performed by Moynihan,[3] by Halstead,[4] who removed with the aneurysm a portion of the subclavio-axillary vein, and also by Braithwaite.[5] The possibility of ligaturing either the first or second portion of the artery is a condition precedent to excision. Both portions were involved in the sac in the case just mentioned.

In a volume on the works of Colles by Robert McDonnell,[6] who was President of the Royal College of Surgeons in Ireland in 1877, the operation of tying the subclavian artery is admirably described. Colles attempted more than once to ligature the first stage of the artery, a far more difficult procedure than ligation of the innominate. He thought that ligature of the first stage on the left side was almost an impossibility, but A. K. Henry [7] has shown that this operation is greatly simplified by an approach from behind.

THORACIC ANEURYSM TREATED BY WIRING

Some years ago (1928) an ex-soldier was admitted to hospital with an aneurysm protruding through the chest wall to the right of the sternum below the clavicle. It appeared on the point of rupture.

The heart and aortic arch were shown in the radiograms to be greatly enlarged. It was thought that rupture might be delayed by consolidation if a wisp of Colt's wire was introduced. A month later the end of the wisp at the point where the wires are joined became superficial and later ulcerated through the skin. The junction was nipped with pliers and all the strands of wire were removed from the aneurysm. Three months after operation the patient died from gradual leakage into the mediastinum and pleural cavity? No post-mortem examination was obtained.

ABDOMINAL AORTIC ANEURYSM

America holds the world's record for thoracic aneurysm treated by wiring and electrolysis. Colt [8] states that Dublin holds the record for abdominal aneurysm treated by wiring alone.

In August, 1910, a patient with a large abdomina aneurysm in the region of the cœliac axis was treated in Mercer's Hospital by the introduction of a cage of Colt's wires (150 in.) into the sac. He died suddenly on March 31st, 1928, approximately 18 years after operation. The doctor in attendance reported there was no abnormality of pulse or temperature, or signs of internal hæmorrhage when he saw him immediately before death, but no post-mortem was obtained.

In a second similar case [9] a wisp of 105 in. of wire was introduced into the sac of the aneurysm. After operation the man was passed as sound for service during the war as a stoker on a patrol trawler in the Naval Reserve. He died of leakage from a secondary dilatation of the aorta below the aneurysm while thus serving, four years and eight months after operation. At post-mortem examination the aneurysm was found completely consolidated. It was about the size of a full-time fœtal head. The wires had expanded uniformly. The specimen is preserved in the surgical museum of Trinity College.

The abdominal aorta was first ligated by Sir Astley Cooper. In 12 cases recorded subsequently the mortality was 100 per cent. Nevertheless, ligature below the renal vessels has been followed by success. Brooks [10] describes and illustrated a case which died of intestinal obstruction three months after successful ligation.

The prognosis of abdominal aneurysm without operation is unfavourable. The duration of the condition is said to vary from three months to three years.

ANEURYSM OF THE POPLITEAL ARTERY

How the more modern conception of the surgery of the blood-vessels comes to our assistance may be illustrated by a case of popliteal aneurysm in a man aged 62.

The aneurysm resulted from a slight injury and had reached the size of a coconut. It had extended upwards from the popliteal space to the opening in the adductor magnus. The patient was a bad surgical risk. He was fat and short necked. His heart was fibrillating, his systolic blood pressure was 220, his pulse-rate 140. His foot was cold and gangrene was impending. The old operation of ligature of the femoral artery would almost certainly have been followed by gangrene. An extensive operation on the sac or amputation, in all probability, would have been followed by death.

A complete cure with restoration of the circulation in the limb followed resection of 1 in. of the artery in Hunter's canal and ligation of the femoral vein.[11] Resection of the artery is a radical form of sympathectomy and in this case produced increased heat and blushing of the foot. The sheath of the artery above and below the ligatures was injected with alcohol, as recommended by Sampson Handley, to ensure against transitory vasoconstriction.

The advisability of ligaturing both artery and vein or the vein alone, when there is a dangerous diminution of the blood-supply to a limb has only been recognised since the war. This recognition, reinforced by a better understanding of the surgery of the sympathetic nerves, has saved many limbs from death in recent years.

ORTHOPÆDIC TREATMENT IN POLIOMYELITIS

IN THE ACUTE AND SUBACUTE STAGES

By Alan H. Todd, M.S. Lond., F.R.C.S. Eng.

ORTHOPÆDIC SURGEON TO THE CROYDON GENERAL HOSPITAL, THE WEST KENT GENERAL HOSPITAL, AND THE ALEXANDRA HOSPITAL, SWANLEY; LATE CHIEF ASSISTANT IN THE ORTHOPÆDIC DEPARTMENT, GUY'S HOSPITAL

In view of the prevalence of infantile paralysis at the present time, it will probably be useful to call attention to the importance of correct treatment in the early stages of the disease. Diagnosis is always difficult until the actual loss of power in certain muscle-groups has become evident. In other words, the disease is fairly well established, as a rule, before the diagnosis is made and treatment is instituted. It is all the more important, therefore, to retrieve as much as possible of the lost ground. Moreover, the right choice of treatment at this stage has a very direct bearing upon the ultimate functional capacity of the patient. It may, and often does, determine the complete recovery or the permanent loss of certain movements. This statement does not imply, of course, that treatment is the only factor that determines recovery of function or failure; that, notoriously, is not the case; for patients vary very much in their power of withstanding the disease and of recovering from its effects. One quite commonly finds that, in one and the same epidemic, two patients who appear to have been affected about equally in similar muscle-groups, and have received identical treatment, differ markedly in their degrees of recovery. The reasons for this are only very imperfectly known; probably several factors are involved, and at present they are beyond our control. But the important point to appreciate is that unless certain conditions, which are known, are satisfied, recovery of the paralysed muscles will be rendered impossible and a recoverable, preventable paralysis will be converted into a permanent one.

Furthermore, the rapidity with which appropriate treatment is begun seems to have a profound effect, not only upon the degree of paralysis that persists, but also upon the duration of restorative treatment necessary. Treatment at present cannot wholly determine the ultimate result of a case; in some cases (but not in all) certain muscles are foredoomed, and we cannot yet save them. But in many cases the muscles are not thus doomed; they possess the capacity to recover, and when they do so they can be destroyed by wrong treatment, they can be caused to recover by right treatment, and the extent to which they will recover, and the time taken in the process, will be largely determined by the speed with which that treatment is instituted. A week gained at the outset will probably save weeks, and possibly months, later on. The resulting material gain is, of course, enormous; many months of attendance at hospital for massage or for the performance of operations, the provision of splints and walking apparatus, and so on, mean a tremendous strain upon the resources of any family. A right choice of early treatment may well determine whether a patient is to be a lifelong cripple or a self-supporting citizen.

PRINCIPLES OF TREATMENT

Standard text-books say little or nothing about the treatment of poliomyelitis in the acute stage. For the most part they content themselves with remarking that the treatment of infantile paralysis consists in massage, electrical stimulation, and the use of appropriate walking appliances, when necessary, and they give no indication as to the stage at which these treatments should be used, or their relative values. The result is that the average doctor is led to believe that electrical treatment and massage are the mainstay of treatment, even when the disease is recent in onset, and the public, who love anything mysterious and incomprehensible, pin their faith to electricity in any shape or form and clamour for it.

It is therefore vital to state, as emphatically as possible, that in the acute stage of infantile paralysis complete rest and relaxation of the affected muscles constitute the one and only indication in treatment as far as the orthopædic aspect of the case is concerned. It is not enough merely to keep the affected muscles at rest, though that is important; they must be physically relaxed as well.

A paralysed muscle that is stretched will not recover. That is certain. There is abundant clinical proof of this fact. If a paralysed muscle be stretched it will not recover, even though it be given electricity and massage. On the other hand, paralysed muscles frequently recover when given relaxation and nothing else. How long the capacity to recover with relaxation persists is not known. It is probable that when once a muscle has been severely damaged by poliomyelitis and by stretching, a physical change takes place in its structure which renders it incapable of full recovery. But if a paralysed muscle be protected from stretching from the outset it may recover to a considerable extent, even after a number of years, and in spite of a severe initial paralysis. The late Mr. T. H. Openshaw once showed at the Royal Society of Medicine a young man whose quadriceps had so far recovered, after the use of a caliper for 19 years, that he was able to discard the splint and enjoy the use of a stable knee-joint; and this was a patient whose initial paralysis was exceedingly severe.

Rest with relaxation is the sheet-anchor of the treatment of infantile paralysis in the acute and the subacute stages. This is fortunate, because it is, as a rule, a treatment that can be carried out easily and cheaply almost anywhere. It sometimes happens that infantile paralysis attacks a patient who is unable, by reason of distance or expense, to attend hospital, and that the only treatment possible is to provide correct splintage and rest at home. A striking degree of recovery often ensues.

Massage and electrical stimulation are undoubtedly valuable in the later, more chronic, stages of the complaint, though even there they are of less relative importance that the continuous protection of the damaged muscles by relaxation in appropriate appliances. If one had to choose, at any stage of infantile paralysis, between efficient splintage and any other method of treatment, the preference should undoubtedly be given to splintage.

It is often stated that infantile paralysis, being an affection of the motor nerve-cells, is painless; but this is not always or even generally true in the earliest stage of the disease, when some pain in the limbs or along the spine is often present. Exceptionally, the pain is severe. In all cases splintage is the most efficient means of relieving this pain. If fixation be good, relief is almost immediate and lasting.

DISTRIBUTION OF PARALYSIS

It is not always easy to know which muscles to relax. When definite loss of power has appeared the proper line of treatment is obvious. But one would wish, if possible, to anticipate this stage in a case in which the diagnosis of acute poliomyelitis seemed probable on other grounds. It is sometimes possible in such a case to feel the flabbiness of the muscles before definite inability to make voluntary movements has appeared; and it is useful to remember that poliomyelitis seldom affects individual muscles, but nearly always certain groups of muscles. If a group-distribution of suggestive flabbiness be observed in a case of probable infantile paralysis, the diagnosis is rendered so probable that treatment by relaxation of that group should be instituted at once.

One knows from experience that infantile paralysis is specially liable to attack certain muscle-groups. For instance, the quadriceps extensor cruris is more likely to be affected than the hamstrings, and the extensor group on the front of the shin is very likely indeed to be affected; more or less foot-drop is still one of the commonest stigmata of a bygone attack of infantile paralysis. As a general rule the paralysis is much more extensive in the early stages of an attack than it is eventually. If, then, one is called upon to treat a patient in the early stage, when no definitive signs have appeared, and several limbs perhaps are paralysed, the best course is to relax those muscles which (1) matter most, from the point of view of ultimate function, and (2) are known from practical experience to be most liable to attack.

THE LOWER LIMBS

In the case of the lower limbs, the quadriceps and the extensor group on the front of the leg are the most important muscles, and are also the groups most liable to be affected. The indication is obvious; the foot must be supported at a right angle with the leg and the knee must be kept straight. (The nurses' beloved pillow behind the knees must here be strenuously avoided.) In the exceptional case, in which the calf was affected more than the extensor group, the reverse treatment would of course be necessary; that is to say, the foot would have to be placed in plantar flexion.

The principle should be carried through, however, to its logical conclusion. One of the commonest defects after extensor paralysis is a flail condition of the toes, which drop down uncontrollably and prevent the putting on of an ordinary boot or shoe. The usual type of splint has a right-angled footpiece, which either stops short of the toes and does not support them at all, or else supports them in the horizontal position midway between extension and flexion. Clearly they should be dorsiflexed by an appropriate cocked-up terminal portion or a suitable pad.

Weakness of the abductors of the hips, and especially of the gluteus medius, profoundly impairs the stability of the pelvis and of the body generally on the lower limbs. Therefore, if the abductors seem to be at all weak, or if both adductor and abductor groups be paralysed, and one does not know as yet which group will ultimately prove to be the more severely affected, the lower limbs should be widely separated to relax the glutei. (The function of the glutei in steadying the trunk upon the lower limbs is even more important than that of moving the thigh in various directions.) Incidentally one may observe that a paralysed gluteus medius is very difficult to substitute, either by the action of other muscles or by surgical operation; one should therefore take all the greater care to protect it when it is damaged.

THE TRUNK

The paralyses of the trunk present a far more difficult problem than any of the limb paralyses. They are not easy to diagnose, though with care one can usually make out which are the preponderating masses that are affected: the effect of gravity comes in to a very important extent; they take, apparently, a particularly long time in recovering; and, most important of all, the functions of all the muscles are important, so that in relaxing any one group the conflicting interest, so to speak, of the opposing group has to be very seriously considered. It is impossible to lay down any fixed rules with regard to the position to be enjoined in any case of paralysis of the trunk muscles; each case must be considered according to general principles. It may be laid down, however, as fundamental that any paralysis, or suspected paralysis, of the trunk muscles necessitates complete and prolonged recumbency. It is probable that many of the cases of severe scoliosis that one still sees in hospital out-patient departments are due to paralysis of the trunk muscles having passed unnoticed and untreated, in face of the much more obvious limb affections. Even so, it is also probable that many trunk paralyses that have in fact been observed have been given insufficient treatment. Three months' complete rest and relaxation are the very minimum, and in most cases a year of recumbency or even longer is the proper period. Such treatment of course involves severe interference with a child's education, and in practice it almost always means residence in a special orthopædic hospital-school; for when the subacute stage has passed, prolonged treatment by massage and the like is indicated, and this can only be obtained in institutions by all but the richest parents. Nevertheless, the time and money are well spent, for thorough treatment of this kind often results in complete or very considerable recoveries even from severe paralyses. On the other hand, lack of treatment, or insufficient treatment, gives rise to some of the most unsightly and disabling deformities. Many of the extreme scolioses that are seen, formerly labelled rachitic, are undoubtedly due to neglected infantile paralysis.

The erector spinæ, the oblique abdominal muscles and the transversalis, and the quadratus lumborum, as well as the ilio-psoas, are all commonly and severely affected by infantile paralysis. The rectus abdominis suffers also, but perhaps less often, and so do the lesser muscles of the trunk. If the back muscle is affected as well as the abdominal, one is in a quandary; if the patient is sat up at all to relax the abdominals the back is being stretched and vice versa. Any raising of the patient is objectionable from the point of view of the action of gravity thus introduced; also the erector spinæ is perhaps irreplaceable, as compared with the abdominal muscles, which can be substituted to some extent by a belt or other device. Therefore, in such a case, it seems best, upon the whole, to keep the patient lying flat. Probably the best relaxation of both erector and abdominal muscles is secured by the prone position. Patients adapt themselves readily to this position, and sometimes indeed prefer it after a few days; at any rate, it seems to be theoretically correct; it gives good results, and it is worthy of being borne in mind as a variant upon the tedious supine position. In the acute stage it is certainly right, except when there is paralysis of the ilio-psoas or of the posterior muscles of the neck—i.e., the upper extremity of the erector spinæ. If the ilio-psoas is specially affected the patient should be raised at the hips, the back being supported flat—that is to say, the hips should be flexed, whilst the trunk lies flat but relaxed on a firm board or other support, hinged to the bed-frame at the level of the hips. The device is identical, in fact, with that devised by Mr. F. G. Ernst for use in Pott's disease would be, in certain respects, an improvement on toxoid-antitoxin.

The qualities which such an antigen should possess may be summarised as follows: (1) rapid induction of immunity; (2) induction of an immunity higher in degree than that conferred by toxoid-antitoxin; (3) induction of immunity, even in "immunologically *obstinate*" *individuals*; (4) *freedom from unpleasant* reactions.

Glenny[2] refers to experimental work on the antigenic effects of an alum-toxoid produced by the addition of aluminium sulphate or potash alum to a diphtheria toxoid.. Of 41 animals treated with alum-toxoid 29 were Schick-negative within three weeks, and all were immune by the fifth week. In the control series none was negative by the third week, and 8 were still Schick-positive as late as seven weeks after injection. Somewhat similar results on a smaller scale were obtained by Ramon by the addition of tapioca to toxoid. Glenny concludes that the increased antigenic response in both cases is due to delayed absorption.

We therefore tried alum-toxoid for immunisation on 436 children (varying from 8 months to 14 years of age). Treatment was commenced in November, 1930, and contact was maintained throughout with Dr. R. A. O'Brien, Director of the Wellcome Research Laboratory, through whose courtesy the necessary supply of materials was obtained.

Experience had already shown[1] that approximately 80 per cent. of unimmunised children were positive reactors. This fact, coupled with the difficulty of inducing parents to submit their children to a protracted series of injections, led us to dispense with the preliminary test, both at the clinics and in the day-schools. There remained, however, a third group of children in two institutions over which it was possible to exercise more complete control, and here a preliminary test was carried out.

The basis of comparison has therefore been worked out under three headings: (1) the percentage of *negative* reactors after immunisation in children treated with alum-toxoid and in those treated with toxoid-antitoxin, and the rate of development of immunity in both groups; (2) the number of *reported* cases of diphtheria occurring in both groups after treatment; (3) the rate of development of immunity in a group of controlled *Schick-positive* children in institutions.

In introducing the alum-toxoid, which is designated A.M.T., the laboratory workers were faced with an almost complete lack of experience of its use with human beings, and had to proceed with extreme caution in regard to the degree of dilution of the toxoid and the proportion of added alum. Four different batches were tried out during the experiment, and in assessing the value of the work done it is important to bear in mind the Lf value[3] of the different batches, which varies in proportion to the dilution of the toxoid and the amount of added alum. The following Table shows the relative composition of the different batches.

TABLE I

Showing the relative composition of different batches of alum-toxoid.

Batch.	Dilution of toxoid.	Percentage of alum.	Lf value.
B6219	1 in 10	0·5	under 1
B6217	1 in 10	2·0	1·5
B6539	1 in 1	7·5	11·0
B6707	1 in 1	9·0	15·0

B6219 was the first batch used; only nine cases were treated with this antigen, which was withdrawn shortly after introduction.

The original procedure was to give a preliminary dose of 0·25 c.cm., and if no unpleasant reaction resulted to proceed to 0·5 c.cm., with two subsequent doses (at fortnightly intervals) of 1 c.cm. each. The procedure with the other batches was somewhat different. With B6217 our experience in the early cases enabled us to proceed straight away with a full primary dose of 1 c.cm. for the later ones without provoking any unpleasant reactions. With B6539 the procedure throughout was to give a preliminary dose of 0·5 c.cm. and two subsequent doses of 1 c.cm. each. The reactions (if any) with both B6217 and B6539 were almost invariably mild, but in one or two instances it was necessary to modify the technique. A similar procedure was used with B6707. No reaction of any consequence ever developed after *the preliminary dose of 0·5 c.cm.*, although there was a greater tendency for reactions to develop after the subsequent injection than there was with the other batches.

RELATIVE POTENCY OF THE TWO ANTIGENS

The findings of Glenny and his co-workers suggested a period of six weeks between tests with alum-toxoid, and this was determined on. In actual practice this period was exceeded in many instances owing to the difficulty of getting the children to attend for the Schick test. Nevertheless a considerable proportion were actually tested within the prescribed period. With toxoid-antitoxin a further difficulty was encountered. Our early experience with this antigen had shown that it was useless to test children within a period of even three months after completion of treatment, as so many of them still yielded positive reactions. The period was therefore extended to six months. It must be borne in mind, therefore, that whereas in the toxoid-antitoxin group the tests were carried out six, nine, and twelve months after treatment, with the alum-toxoid the tests were performed in so many weeks. Nevertheless, the results have been sufficiently striking to justify the expectations on which they were based, and to serve as an index of the relative merits of the two materials as immunising agents.

TABLE II

Toxoid-antitoxin. Analysis of results of Schick tests carried out after treatment.

Interval*	Results of Schick test.		Percentage. Neg.	Interval*	Results of Schick test.		Percentage. Neg.
	Neg.	Pos.			Neg.	Pos.	
months.				months.			
4	25	8	75·7	10	79	9	89·5
5	203	59	77·0	11	92	13	87·6
6	223	66	77·1	12	55	10	84·6
7	93	23	80·1				
8	163	25	86·1	Totals ..	999	231	81·2
9	66	18	78·5				

* Interval in months between last injection and date of Schick test.

Table II. represents 1230 children. In the subgroup tested within four months of treatment only just over 75 per cent. were negative. The figures for the five-month and six-month periods are slightly better, but it is not until the seven-month and longer periods are reached that the desired results are obtained—80 to 85 per cent. of negatives. In the group as a whole 81·2 per cent. were negative. There is a curious variation in the ratios in the various groups, which can only be attributed to idiosyncrasy. For instance, the maximum proportion of negative reactors (89·5 per cent.) occurs in the ten-month group, while the eleven- and twelve-month groups show a progressively smaller proportion of negatives.

Table III. comprises 270 individuals. In addition, there were 166 cases who failed to present themselves for the Schick test, and have therefore not been included for comparative purposes. It is to be read in conjunction with Table I. There is a very marked improvement in the figures as measured by the proportion of resultant negative reactions. This depends upon whether the figures bulk largely in the interval period, 0 to 6 weeks, or in that of 7 to 12 weeks. This is what one would naturally expect, and it is necessary therefore to analyse the figures further.

TABLE III

Alum-toxoid. Analysis of results of Schick tests carried out after treatment.

Interval*	Results of Schick test, with batch numbers of materials.							
	B6219		B6217		B6539		B6707	
	Neg.	Pos.	Neg.	Pos.	Neg.	Pos.	Neg.	Pos.
4 weeks	—	—	6	—	—	—	—	—
5 ,,	—	—	17	2	—	—	—	—
6 ,,	—	—	21	3	65	7	—	—
7 ,,	—	—	27	—	3	—	7	—
8 ,,	—	—	20	—	2	—	5	—
9 ,,	—	—	—	—	4	—	9	—
10 ,,	—	—	3	—	6	—	18	—
11 ,,	4	1	3	—	9	—	13	—
12 ,,	2	2	9	—	—	—	2	—
Totals ..	6	3	106	5	89	7	54	—

* Interval in weeks between last injection and date of Schick test.

With B6219 all the cases come within the latter group, so that no further examination is necessary. With B6217 49 cases were tested within six weeks and 62 between seven and twelve weeks. In the former group 86·2 per cent. were negative and in the latter 100 per cent., while the group taken as a whole over the full period of twelve weeks yielded 95·5 per cent. of negative reactors. With B6539 72 children were tested on the expiration of six weeks as compared with 24 during the seven- to twelve-week period, and, as one would therefore expect, the group taken as a whole yields a slightly smaller proportion of negative reactors than the B6217 group. It is found, however, that of the 72 cases tested after six weeks no less than 90·2 per cent. yielded negative reactions, which is a very good showing indeed. As with B6217, of these tested between six and twelve weeks (24 in number) 100 per cent. yielded negative reactions. With B6707, all the cases were tested more than six weeks after treatment and all gave negative reactions.

These results may be summarised as follows:—

TABLE IV

Results of Schick tests carried out after treatment with different batches of alum-toxoid.

Percentage negative—	B6219	B6217	B6539	B6707
Over whole period ..	66·6	95·5	92·7	100
In 6 weeks (and under)	—	86·2	90·2	—
From 7 to 12 weeks ..	66·6	100	100	100

In view of these figures it seems reasonable to assume that alum-toxoid will induce a rapid and high degree of immunity.

INCIDENCE OF "IMMUNISED" CASES AMONGST THE DIPHTHERIA NOTIFICATIONS

Three alum-toxoid cases were notified. Two of them (brother and sister) were treated with B6219, receiving 0·5 c.cm., 1 c.cm., and 1 c.cm., on each of their three visits.

In one case diphtheria ensued within three weeks of the last injection, in the other six months later. Neither child had been Schick-tested after treatment. The Lf value of this batch is very low (less than unity). In the third case the batch used was B6217 and only one injection of 0·5 c.cm. had been administered. The child did not attend for the subsequent treatment and contracted diphtheria six weeks later. One may reasonably state, for practical purposes, that there has been no case of diphtheria reported among children treated with alum-toxoid, regardless of whether such children have been subsequently Schick-tested or not.

The confirmed attack rate among the toxoid-antitoxin cases in 1930 was 2·35 per 1000 (as compared with an attack rate of 25·69 per 1000 among non-immunised children under 15 years in Cork City during the year 1930), but if one includes all cases notified the rate is raised to 10·73 per 1000.

The occurrence of such cases has a deterrent effect. Of the 50 reported cases, the diagnosis of 19 was not confirmed after admission to hospital. Follicular tonsillitis furnished the bulk of them, but there were also cases of simple tonsillitis, membranous rhinitis, scarlatina, and "septic sore-throat." It is difficult to suggest how such cases can be avoided with any immunising agent, but nevertheless it is a curious and significant fact that there has not been so far a single such occurrence among the 436 children treated with alum-toxoid.

THE SCHICK TEST IN CONTROLLED CHILDREN IN INSTITUTIONS

There are but two suitable institutions in Cork, both of them orphanages, and they were placed at our disposal by the authorities. The procedure was to perform a preliminary Schick test; the positive reactors were then segregated into two groups, one of which received alum-toxoid and the other toxoid-antitoxin. Six to seven weeks later both groups were again tested and the results noted. Curiously enough our results with the preliminary Schick test in both these institutions were completely different from those obtained among children generally in the city. The two institutions together furnished 405 children, of whom only 38·5 per cent. were positive, as compared with 80 per cent. among the general school population. Dr. H. J. Parish informs me that similar results have been obtained in poor-law schools in England. He estimates that in the average industrial school the immunity rate is in the neighbourhood of 60 per cent.

In order to ensure that exposure to infection should be as even as possible, each group was divided into classes; these classes were further subdivided as evenly as possible, one portion receiving alum-toxoid and the other toxoid-antitoxin. The first doses of prophylactic were administered early in April, 1931, and subsequently at fortnightly intervals. The alum-toxoid used was B6539. In the first instance 0·5 c.cm. was given and two further doses of 1 c.cm. each. Of toxoid-antitoxin 1 c.cm. was administered on each occasion. Approximately six weeks after the last injection the children received the secondary Schick test. The elimination of the original negative reactors, together with leakage caused by leaving school, reduced the number of cases submitted to the final test to 142. This is, admittedly, small but the results are sufficiently striking to justify publication, particularly as they conform closely not only to our own experience among the child population of the city generally, but also to the results obtained by Glenny with guinea-pigs.

TABLE V

Analysis of results of Schick test in children in institutions after treatment with alum-toxoid and toxoid-antitoxin (all cases).

Prophylactic.	Cases.	Neg.	Pos.	Percentage negative.
Alum-toxoid ..	73	59	14	80·8
Toxoid-antitoxin	69	41	28	59·4

Taking the group as a whole, 80·8 per cent. of those treated with alum-toxoid were negative as compared with 59·4 per cent. of the toxoid-antitoxin cases. In view of the comparatively indeterminate character of the figures, it was decided to make a further analysis on the basis of the nature of the original Schick reaction. Following the usual procedure this had been classified as "slight," "moderate," or "marked," according to the character and extent of the resultant inflammation. Owing to the unexpectedly large number of negative reactors and the consequent reduction of material for the experiment, there would seem to be no doubt now when reading the results of the preliminary tests that there was a marked tendency to include among the "slight" group a large proportion of cases which in the ordinary course of events would be classified as negative, with a consequent vitiation of the ultimate figures. This assumptiom receives confirmation from Table VI., in which the results have been separately analysed for the three groups.

TABLE VI

Analysis of Schick tests carried out after treatment, according to the nature of the original Schick reaction.

Nature of original reaction.	Prophylactic.	Cases.	Neg.	Pos.	Percentage negative.
Slight	A.M.T.	34	29	5	79·6
	T.A.M.	36	27	9	75·0
Moderate ..	A.M.T.	20	17	3	85·0
	T.A.M.	29	13	16	44·8
Marked ..	A.M.T.	19	13	6	63·4
	T.A.M.	4	1	3	25·0

There is no material difference between the two subgroups in which the original reaction was classified as "slight." This is what one would expect if the majority of the children composing the group were originally negative and not positive (or even slightly positive). There was a strong element of doubt in the reading of the original reaction, so that the two sets of figures do not serve well for the purpose of comparing the relative merits of the two prophylactics. In the "moderate" group there is a striking difference between the end-results. The cases treated with alum-toxoid yield 85 per cent. of negative reactions, as compared with 44·8 per cent. yielded by those who received toxoid-antitoxin. There is a similar differentiation in the group classified as "marked"—63·4 per cent. of negative reactors with alum-toxoid and 25 per cent. with toxoid-antitoxin. Both these groups were composed of children who exhibited definite and unmistakable positive reactions with the preliminary test. Taking the two groups together the proportion yielding negative reactions after alum-toxoid is 76·9 per cent., as compared with 42·4 per cent. after toxoid-antitoxin. These are the significant figures, and there is little doubt that they reflect the relative efficacy of the two antigens.

It seems clear that alum-toxoid is a definite advance on toxoid-antitoxin. The figures adduced have received confirmation in the recently published work of Park and Schroder [4] who have shown, both in children and guinea-pigs, that it has given better results than either toxin-antitoxin or formol-toxoid. Two hundred and twenty-eight children immunised with alum-toxoid gave an immunity rate of 98·2 per cent., as against 90 per cent. with toxin-antitoxin and 93·7 per cent. with formol-toxoid.

CONCLUSIONS

1. These observations are based on experience of 436 children treated with alum-toxoid and over 7000 treated with toxoid-antitoxin.
2. Alum-toxoid is superior to toxoid-antitoxin in the prevention of diphtheria. It induces immunity more rapidly.
3. In epidemic periods, when rapid induction of immunity is essential, alum-toxoid is the best antigen.
4. When administered in properly graduated doses the reactions caused by alum-toxoid are not more severe than those caused by toxoid-antitoxin.

Clinical and Laboratory Notes

IRRITATION OF THE VAGUS BY A TUMOUR OF THE CAROTID BODY

BY MAURICE COKE, M.R.C.S. ENG.
LATELY SENIOR RESIDENT MEDICAL OFFICER, WESTMINSTER HOSPITAL
AND
H. A. DUNLOP, M.D., M.R.C.P. LOND.
LATELY MEDICAL REGISTRAR TO THE HOSPITAL

THE condition of the autonomic nervous system known as vagotonia, representing functional derangement rather than gross structural alteration, has been regarded by Eppinger and Hess [1] as resulting from a disturbed balance of endocrine secretion. However little favour the endocrinological aspect of the theory has received, there can be no doubt that patients are occasionally encountered whose symptoms are most reasonably explained in terms of vagotonia. Such patients receive some benefit from the administration of atropine, but this often to a lesser degree than might be expected because usually only one set of branches of the vagus is seriously involved, and since the over-excited terminals are less susceptible to the action of the drug than are the normal ones.

Stimulation of the vagus by the pressure of neoplasms is recognised, although paralysis is more commonly observed. In any case, the visceral effects are not usually obtrusive. Carotid body tumours may excite the vagal functions, but so far we have not seen a record of such severe and long-continued over-activity as in the case presently to be described. Stanford Cade,[2] in a paper in which many references to the literature will be found, points out the frequency of pain due to the pressure of these tumours on the cervical plexus. This author also mentions that dyspnœic and syncopal attacks occurred in one patient in whom, moreover, digital pressure on the tumour caused a sensation of giddiness.

THE CASE DESCRIBED

The present case was that of a man, aged 36, who was admitted to the hospital in January, 1930, under the care of Sir James Purves-Stewart.

The patient was a labourer by occupation, and complained of abdominal pain, vomiting, and breathlessness. The pain was of a dull aching character, and was felt in the left side of the epigastrium where it began about one hour after each meal. From this point it spread upwards into the left side of the thorax and downwards into the left iliac fossa. Vomiting then occurred, giving relief of the pain. Some relief was also obtained by lying down or by taking bismuth. The occurrence of these symptoms, epigastric pain and vomiting, dated from August, 1928, a few weeks after convalescence from an illness diagnosed as pneumonia, and during the one and a half years of their duration the longest period of freedom was two days.

In December, 1929, the patient experienced severe giddiness and breathlessness, which subsequently abated, leaving breathlessness and palpitation on exertion only. Constipation was severe throughout the period of illness, and during the three weeks prior to the operation presently to be described the bowels were opened on five days only, with the help of purgatives and enemata. Loss of weight was complained of, but no accurate figures are available.

Examination of the moderately emaciated patient showed pallor of the skin and mucous membranes, and coated tongue. A tumour of firm consistency was palpable a little way below the left angle of the lower jaw, deep to the sternomastoid; it was not attached to the skin, and felt as though it was composed of "several glands matted together."

In the abdomen the upper part of the left rectus was rigid and tender; there was no cutaneous hyperæsthesia. The central nervous system and cervical sympathetic were normal. The vocal cords moved normally. The lungs were normal to physical examination. The respiration-rate was 20 to 25 per minute.

The pulse-rate at the time of admission was 80 per minute. It subsequently fell to 52 for a period of six days, but before operation it had risen to 80. Otherwise the heart appeared to be normal. The blood pressure was 110/75 mm. Hg.

The blood count was as follows:—

Red cells	3,630,000	Polymorph	70 %
White cells	8,400	Eosinophil	0
Hæmoglobin ..	53 %	Lymphocytes ..	27 %
Colour-index ..	0·7	Monocytes	3 %

The blood Wassermann reaction was negative.

Unfortunately, a fractional test-meal could not be carried out as the passage of the tube gave rise to distressing vomiting. A single examination of the gastric contents showed absence of free hydrochloric acid and a total acidity of 0·072 per cent. No occult blood was detected in the stools. A barium meal and radiogram of the chest showed no abnormality of the stomach, but there was 48 hours' delay in the ascending and proximal half of the transverse colon.

On Feb. 4th Mr. William Turner removed the tumour. The operation proved not easy, as the

509³ Mrs Kennedy – Dr [illegible]
Diabetes mellitus
Probable bronchopneumonia.

Danielopolu and his co-workers[3] claim to have demonstrated that the carotid reflex is *amphitropic* in action; that is to say, it has both a pressor and a depressor component. The fluctuating pulse-rate of the present case can readily be understood in the light of this observation. The same conception as that of Danielopolu is implicit in a communication by Prof. R. J. S. McDowall to the Physiological Society.[4] This observer noted that when the carotid sinuses had been painted with cocaine, the application of warmth to the skin caused a marked fall in arterial blood pressure, but not in every case; in some of the experiments the vagi had been cut so that part of the response may have been made possible by loss of the vago-pressor reflex. The normal slowing of the heart beat which occurs when the vagus is compressed in the neck is due to pressure on the carotid sinus rather than on the vagus itself, and the giddiness which ensued when this was done in Stanford Cade's case, referred to above, probably represents an exaggerated example of this phenomenon.

The constipation was undoubtedly due to vagal stimulation, since it was relieved from the day following the operation. The reason why pathological stimulation of the pneumogastric nerve should cause constipation is not clear, since the physiological teaching is that the action of this nerve on the gut is to increase peristaltic movement; possibly spasm may be set up. It is noteworthy that in the present case there was no delay—rather the reverse—in the passage of contents through the stomach and small intestine, but that there was great retardation in the ascending colon and proximal half of the transverse colon. Both of these regions of the large intestine are innervated by the vagus, in contrast to the distal colon which is supplied by the sacral autonomic nerves.

As to whether in cases such as the present one the afferent or efferent fibres of the pneumogastric are chiefly affected is unknown.

We wish to thank Sir James Purves-Stewart and Mr. William Turner for permission to publish the case. To Dr. Braxton Hicks we are indebted for the histological findings, and to Dr. David de Souza for much helpful advice.

THE BARIUM ENEMA IN THE DIAGNOSIS OF INTUSSUSCEPTION

BY R. HODGSON BOGGON, M.S. LOND., F.R.C.S. ENG.
CHIEF ASSISTANT IN THE CLINICAL SURGICAL UNIT, ST. THOMAS'S HOSPITAL

THE object of this short communication is to remind those engaged in the active treatment of acute abdominal lesions that the barium enema is of value in the diagnosis of doubtful cases of intussusception in infants. It is not claimed that the method is new, for papers have been published on the subject on the continent and in America as far back at least as 1913,[1] and while I was preparing these notes an example was published by Dr. Reginald Miller.[2] The text-book case of intussusception in an infant can be diagnosed with ease by the ordinary clinical methods of examination; but there are cases, usually of the subacute variety, in which diagnosis is not so simple. There is usually sufficient evidence to put the patient under suspicion, but insufficient to warrant an exploratory laparotomy. It is in these that the assistance of the barium enema settles the matter, as shown by the two cases described here. In advocating this additional diagnostic procedure, it is fully realised that it can only be carried out when working under ideal conditions. A competent radiologist with his X ray plant is required, and this usually means that the patient must be in a large hospital at a reasonable time of day.

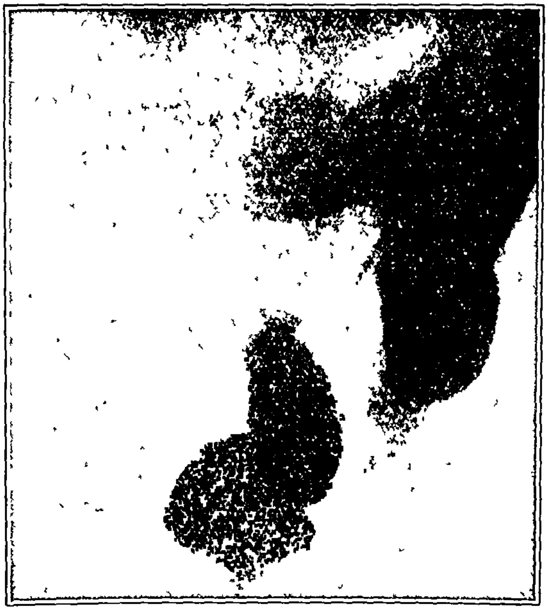
[2] Arch. Dis. Child., August, 1932, p. 201.

CASE 1.—Girl aged 2 years. First child; breast-fed. She was admitted on Feb. 2nd, 1930, with four days' intermittent attacks of colicky abdominal pain. There was no vomiting, and the bowels had been opened once, but the motion contained no blood or mucus. The child looked well, and on examination of the abdomen a tumour was felt just above the umbilicus. This, however, disappeared shortly after examination. On the following day, as the diagnosis was still in some doubt, a barium enema was given and the X ray taken by Dr. Geoffrey Fildes. This revealed the presence of an intussusception with the apex in the transverse colon (Fig. 1).

Laparotomy was performed immediately and the intussusception found almost reduced, presumably by the enema. Reduction was completed in the act of withdrawing the cæcum from the abdomen. It was of the ileocolic type. The patient made a good recovery.

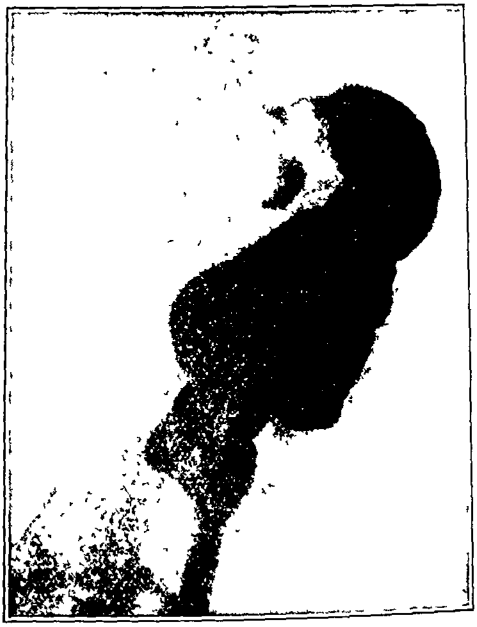
FIG. 1



Intussusception in the proximal half of the transverse colon.

CASE 2.—Boy aged 6 months. Admitted on August 10th, 1932. He was a first-born and breast-fed. Two days prior to admission the mother noticed that he was disinclined to take his feeds, and commenced to vomit. This was shortly followed by attacks of screaming. The bowels were opened the day before admission by means of castor oil, and no blood or mucus was then noticed by the mother. The child on examination appeared perfectly normal and healthy, except that a movable tumour could be felt just to the left of the umbilicus. The tip of the finger, after being inserted high into the rectum, was smeared by a little dark-coloured blood. Barium enema radiography was carried out by Dr. Bertram Shires, and this showed an intussusception, which had reached the left half of the transverse colon (Fig. 2). Operation was performed immediately and the intussusception reduced. It originated from the outer and lower part of the caput cæci. Recovery was uneventful.

FIG. 2



Intussusception in the distal half of the transverse colon.

The X ray appearances are characteristic, for the barium can be seen insinuating itself between the intussuscipiens and the intussusceptum, and also outlining the mucosal folds resulting from the concertina-like effect of the intussusception on the bowel. The position of the apex is also indicated at the time the picture is taken, but it must be remembered that the enema may in part reduce the intussusception, as in Case 1. This partial reduction should not be a temptation to postpone operation on the grounds that total reduction may occur.

As the opaque enema is a comparatively simple procedure, and the effect on the child merely that of discomfort, it seems reasonable to consider its use in doubtful and subacute cases, for the additional evidence obtained makes the diagnosis conclusive.

I am indebted to Sir Percy Sargent and Dr. R. C. Jewesbury for permission to publish the notes of these two cases.

SALFORD ROYAL HOSPITAL.—The annual report calls attention to a serious lack of adequate accommodation at this institution, to a great extent in consequence of "the rapid growth of specialised medical science." Plans for improvements have been prepared, but cannot be carried out for lack of means, and in the meantime an adjoining building is being temporarily taken over. The report of the medical board states there is still a good deal of unavoidable waiting for admission, particularly on the surgical side. The large number of industrial accidents and the increasing number of motor injuries occupy many beds which would otherwise be available for general surgical work. There is great difficulty, with the present inadequate out-patient accommodation, in dealing with the increasing number of patients who attend this department. It is added that of all the large hospitals in Manchester "the pathological department is the worst equipped." Notwithstanding these difficulties an out-patient clinic for cases of early mental disorder has been established under the Mental Treatment Act in collaboration with the Lancashire mental hospitals board. Dr. A. Corsar Sturrock, who has retired from the active staff of the hospital, is taking charge of the clinic.

MEDICAL SOCIETIES

ROYAL SOCIETY OF MEDICINE

SECTIONS OF SURGERY AND MEDICINE

At a joint meeting of these sections on Nov. 2nd the chair was taken by Mr. HUGH LETT, President of the Section of Surgery, and a discussion on the

Treatment of Acute Appendicitis

was opened by Dr. J. A. RYLE. This problem, he said, was really a complex problem in judgment; it could not be decided by statistics or opinion, but only by a pooling of experience and careful analysis of clinical records and of the factors contributing to success and failure. The cultivation of judgment in modern medicine, however, had not proceeded pari passu with the cultivation of technique. Decisions might be warped as well as expedited by the knowledge that inaction might cause disaster. If Sir James Berry's address on Fallen Idols[1] had done no more than arouse thought and controversy, it had been valuable. A bare diagnosis of appendicitis was not enough; the stage and type of the pathological process must be visualised. There could be no antagonism between the medical and the surgical mind, and there could be no "always"; a best procedure for each contingency must be discoverable. Physicians tended too readily to visualise the worst and to be too vague in their images of what was happening. They saw to-day far fewer cases of acute appendicitis than the surgeon, but more often the "problem" case or the complicated case. Some surgeons of to-day stood in need of the "physicianary" qualities of an earlier age. Collaborations between surgical and medical minds were too rare in these rushed days. There was need for medico-chirurgical team-work.

Both personal experience and hospital figures suggested that the outstanding cause of mortality was still delay in diagnosis, while the most dangerous type and the type most often and easily missed was Wilkie's obstructive type. If there was obstruction there should always be immediate operation. It was characterised by pain, continuous or at first colicky, but always severe, and not accompanied by inflammatory symptoms such as pyrexia, increased pulse-rate, or rigidity. Surgical interference was not an appreciable cause of mortality. In the inflammatory type delay and medical treatment might be justifiable; interference in the "middle" period might be dangerous and cause spread of infection or ileus. The most difficult decision arose in cases first seen with symptoms of ileus or obstruction; in these cases especially, collaboration between physician and surgeon was desirable. Sometimes the patient might be tided over for a few days by medical measures, until greater localisation was obtained and operation became less risky.

The delay in diagnosis might be due to unwisdom of the patient, the parent, the schoolmaster or matron, the general practitioner or the surgeon. The chief thing to be desired of the general practitioner was greater knowledge of signs and symptoms and ability to recognise the obstructed type. Dr. Ryle's recommendations were as follows: (1) for the inflammatory case, the interval operation or—if operation were undesirable—a watching brief; (2) for circumscribed abscess, simple drainage at the most favourable moment, by the most favourable path and with the minimum of interference; (3) for the obstructive or gangrenous type, immediate operation; and (4) for the late case with distension and signs of obstruction, a consultation. The essential factors in the problem were alimentary rest for the patient and a mental picture of the pathology for the doctor.

A SURGEON'S VIEW

Mr. H. H. RAYNER protested at the suggestion that surgery was making no progress in this disease. The statement was based on the Registrar-General's return: that there had been a steady mortality-rate for the last 20 years. In fact, however, case-mortality had been more than halved in the last 20 years; the figures were not accounted for by increasing operation on mild cases which had previously recovered under medical treatment. There had been a remarkable increase in the number of cases, and the improvement in the operation figure was due to earlier and better diagnosis. The proportion of operations in the first 24 hours had increased considerably.

The terms "early" and "unperforated" appendix were not synonymous, but the proportion of unperforated appendices removed could only be raised by insisting on the need for early operation. An appendix might perforate at any time in an attack—or never. The mortality of removal of the unperforated appendix did not exceed 1 per cent.; it was therefore obviously the duty of the surgeon to urge immediate operation in all cases. To secure early and accurate diagnosis, the clinical features at the onset must be recognised. In practice the fundamental question was: Has this patient got acute appendicitis or not? This was more important than: Has this patient got an obstructive appendicitis or not? The doctor should not attempt to discriminate degrees of severity in the ordinary case. Many patients did not seek medical advice for two or three days, and a serious result might follow the lack of rest and unsuitable diet. The pain was often mild for the first day or so. The most difficult type of appendix to diagnose was the pelvic type, for there might be no physical signs except per rectum. The public—especially those in charge of children—needed some knowledge of early symptoms. Early operation under proper conditions reduced the risk of death from 14 per cent. to 1 per cent., greatly reduced morbidity, and obviated the risk of recurrence. "Proper conditions" included a suitable state of the patient; contra-indications were: senility, excessive stoutness, cardiovascular abnormalities, and severe arthritis. On the third day and afterwards there were grounds for prognosis and estimate of the pathological state. Patients seen for the first time at this stage were in a different class from those seen earlier. There were three types: the subsiding; those with localised peritonitis; and those with widespread peritonitis. Operation should be performed at once on patients with general peritonitis. About half the cases with localised peritonitis would settle down, but cases not operated on must be watched carefully, as they might deteriorate and lose their chance. Those who did not settle down might develop abscess. The following types were suitable for expectant treatment: (1) those in which muscular rigidity was localised to a comparatively small area of the abdominal wall; (2) those in which there was a palpable mass—if this subsequently became an abscess the patient did better after a later drainage operation than after an operation on an early abscess with a friable appendix at its centre. The indications for immediate operation were: (1) history of recent severe exacerbation of pain; (2) presence of marked acute tenderness; (3) evidence of toxæmia in the facies, pulse-rate, and temperature. The clinical and pathological features were the foundation of treatment.

---

[1] THE LANCET, 1932, i., 1027.

The anæsthetic for toxæmic patients should be spinal or gas and oxygen; the additional toxic effect of ether was enough to turn the scale against the patient.

DISCUSSION

Dr. H. MORLEY FLETCHER agreed with both the openers. He found it difficult to interpret the contradictory statistics and suggested that a great many appendicectomies were performed in diseases (such as typhoid fever) for which the appendix was not responsible. There had been a great fall in the number of operations during the war period. One point should be strongly emphasised: operation should always be immediate in children. The ileocæcal glands should be examined, as sometimes they were acutely inflamed although the appendix was healthy. If inflamed they should be removed, to avert possible tuberculous peritonitis later. If the patient was seen on the third day and seemed quiescent, the starvation and bowel rest régime should be maintained.

Mr. R. DAVIES-COLLEY doubted if anyone would question the value of operation within the first 24 hours. In the middle stage there seemed to be a tendency to teach that the right routine was to watch, and only operate if things were going wrong; that even an abscess should be allowed almost to point through the skin before interference. He was strongly opposed to delay in that stage unless operation was definitely contra-indicated. Mortality in his opinion was not due to bad choice of a time but to bad technique. There was no great risk in operating on early spreading peritonitis, and the physical signs in these cases were very anomalous. One possible cause of death was faulty diagnosis. Appendicitis was three times less common in women than in men, but women figured quite largely in the Registrar-General's figures. Operation in the acute phase of salpingitis was well known to be dangerous. If there was any real doubt of the diagnosis it was better to wait and watch.

Dr. LEONARD FINDLAY was quite unable to reconcile the physician and the surgeon on this subject. What was wanted was not so much "judgment" as the ability to make a diagnosis. Whenever the diagnosis was made, operation should be performed. He had never regretted the ruling of immediate operation—at any rate in children. Surgeons did not sufficiently often ask the physician to help in diagnosis. Cases of pyelonephritis, cystitis, and lobar pneumonia had all been operated on for appendicitis. It was a good rule to say: If you can't find anything and you suspect appendicitis, behave as if it were appendicitis. He had seen several severe cases of delayed anæsthetic poisoning after up-to-date ether anæsthesia.

Mr. JOHN MORLEY thought that it was not sufficiently realised that in the very early hours of the attack the localised tenderness and rigidity were often quite absent and examination revealed nothing. The patient simply complained of diffuse colicky pain in the upper abdomen. Occasionally Wilkie's fulminating peritonitis was seen, but Wilkie seemed to suggest that early cases could be divided into inflammatory and obstructive types. Mr. Morley, however, thought that a large majority of cases were obstructive, but that cases varied very much in the speed of progress. There was no means of telling which would be fulminating and which benign. A good deal depended on the position of the perforation; some of the worst were at the base of the appendix, allowing gas and fæcal contents to leak from the cæcum. Another factor was the position of the appendix; the pelvic appendix was sinister. The old teaching on cutaneous hyperæsthesia had, he was glad to gather, been dropped. Spinal anæsthesia was very much safer than general; the surgeon could operate with much less trauma to the patient and much greater ease to himself.

Mr. A. J. WALTON thought there were three distinct pathological types: (1) Wilkie's; (2) one in which the infection began as a colitis and localised in the appendix; and (3) a hæmatogenous type, as seen after influenza epidemics. Clinically, however, it was often quite impossible to distinguish the types, and there was no value in attempting to recognise them. Statistics were valueless. The real problem was the third-day appendix. No good could be gained by leaving a diffuse peritonitis; such a case must be drained. Nor was it any use leaving a gangrenous appendix. He did not believe there was such a thing as a "subsiding" appendix; it might perforate at any time. There was a danger of spreading infection from a localised abscess, but technique should overcome this. The interim operation had a high mortality; there might be dense adhesions and a caseous mass inside. Thus, he advised urgent operation in all cases. The one exception was the very fat patient, and that was the danger of any operation and not of appendicectomy. To do the greatest amount of good to the greatest number of patients there was only one rule: operate as soon as you can.

Mr. HERBERT BROWN stressed a risk of operating on an apparently simple abscess in the middle of the first week; until the end of the first week there was no general immunity, and swabbing the cavity might disturb the protecting lymph layer, causing fatal septicæmia. In no circumstances, he thought, should an abscess cavity be manipulated before the end of the first week. The only treatment for the septicæmia would be intravenous mercurochrome. The only septicæmia he had seen in an "early" case (more than 24 but less than 48 hours) had followed a perforation at the base, which had been crushed, thus driving organisms into the blood.

Mr. J. B. HUNTER argued for immediate operation. At University College Hospital, he said, where all cases were operated on immediately they were diagnosed, the total mortality had been about 3 per cent. In children the necessity was urgent. The mortality-rate over the age of 10 was about 2 per cent., and under that age about 8 per cent. Nobody could tell what was happening in an abdomen.

Mr. ZACHARY COPE was certain that there were cases in which it was better to wait. If the appendix was known to have perforated and there was a lump, the resistances of the patient were combating it, and if the lump steadily became smaller the result of operation would be better after a few days' semi-starvation and rectal fluids, when the pus was thicker. Delay was also helpful for generalised peritonitis, as a limited operation might become possible. Ileus with a rapid pulse should also be treated expectantly, with gas gangrene serum. To say that operation should always be performed at once was to allow the clinician no judgment at all. Typhoid might be very difficult to diagnose in children; he had seen a true ulcerative appendicitis in typhoid fever.

The PRESIDENT recalled the discussion on this subject at the Medico-Chirurgical Society in 1905, when the mortality had been enormous: 75 per cent. for peritonitis. At the London Hospital only 6 per cent. of the cases operated on had not been complicated by abscess or peritonitis. In 1912–13 the figure had been more like 54 per cent. The mortality-rate was 4·3 per cent. in the later series, whereas in the original series it had been 24 per cent. In the old days the Trendelenburg position had been the rule for all abdominal operations, and the saline treatment had not been introduced. Very great judgment was called for in the third to fifth-day cases; when in doubt he thought it better to operate. It was not wise to broadcast any advice to delay, as the surgeons with smaller experience throughout the country might tend to delay in those cases in which operation was essential.

Dr. RYLE, in reply, said that no broad basis of agreement had been reached. If Mr. Walton's doctrine were broadcast it would be as productive of disaster as Sir James Berry's. Surgical skill throughout the country was not uniform. The decision had to be made in the individual case every time. Judgment could be cultivated and trained. Any extreme would be bad as a general doctrine for the profession.

Mr. RAYNER confirmed Dr. Ryle's concluding words, and disagreed with Mr. Walton. The surgeon should not be stampeded into unnecessary or premature operation because he could not tell what was going on inside the abdomen. A maintained high temperature suggested gangrene however well the patient might feel, and there was always some such indication. A subsiding appendix was one that was rapidly approximating to normal, and the surgeon surely had an idea of the normal abdomen. He had not found any risk in the interval operation. The longer the case took to subside, the longer should operation be delayed; at least two months should always elapse.

SECTION OF PSYCHIATRY

A MEETING of this section was held on Nov. 8th, when Dr. H. DEVINE gave his presidential address on the

Problem of Schizophrenia

He said that although much important psychological, biological, and clinical research has been carried out on schizophrenic patients, we are still not in a position to state in a few words why these patients are ill, or how to cure them. Recent statistical studies of the results of various forms of active treatment had shown that the remission-rate among treated cases does not differ materially from that among untreated cases. To the psychiatrist whose work is confined to mental hospitals the dementia præcox problem was a very real one, since a large majority of his confirmed cases were schizophrenics. The picture of regression presented by such patients was peculiar. They lived in a world of their own, shunned social contacts, were indifferent to their environment, comfort, or appearance; they exhibited curious mannerisms; many had to be washed, dressed, and fed, and were it not for nursing care they would cease to exist. They lived in a state of spiritual isolation from their fellows; wealth, success, knowledge, culture, and even love, meant nothing to them. In spite of outward appearances these patients were not devoid of an inner psychic life. Observation of advanced schizophrenics had shown them to be aware of their surroundings and they all had the capacity for remembering past events. A katatonic and inaccessible patient might suddenly exhibit a change of phase and loquaciously pour out a stream of delusional talk, revealing thus an unsuspected richness of inner experiences.

In dealing with such non-coöperative patients the psychiatrist was at a disadvantage, for the patient's delusional outlook was so remote from normal thought that there could be no mutual understanding between doctor and patient such as obtained in other kinds of illness. The morbid thoughts which surged into the patient's consciousness, and which he expressed in symbols, described experiences which struck no emotional chords, because the listener was unable to draw upon anything within the range of his waking experience which was commensurate with that of the patient.

But a normal person had experiences when asleep which might enable him to understand in some measure the phenomenal world of the schizophrenic. Jung suggested that if the dreamer should go about performing actions we should have the clinical picture of dementia præcox. Perhaps even more allied to schizophrenic experiences were these temporary psychoses to which we all might be subject under the influence of various kinds of physiological stress.

Schizophrenia was not a rigid disease entity of known causation and of more or less uniform course and outcome. It would seem permissible to take the view that given certain conditions everyone is liable to exhibit schizophrenic reactions.

INNER LIFE OF THE SCHIZOPHRENIC

The cognitive, sensational, and intellectualistic schools of psychology provided us with no knowledge of human nature. Similarly, the idea so dear to Kraepelin, Nissl, and Alzheimer that the primary object of scientific psychiatry should be the study of the cellular modifications of the cerebral cortex, and their relationship to the symptoms manifested during life, did nothing to enable us to understand our psychotic patients as suffering and bewildered personalities. It was only when Freud and Jung began to seek for the origin of the phantasies of the neurotic and the insane in the unconscious biological tendencies, and the pathologist began to investigate the internal secretions and the physiological behaviour generally of these patients, that we were able to gain some understanding of the why and wherefor of their symptoms. It was not difficult to see in certain psychoses the happy realisation of desires that had never been adequately satisfied. Wish-fulfilment mechanisms were quite frequent in benign psychotic conditions.

Dr. Devine described various patients whose morbid psychic productions were of the non-logical autistic type, and who showed a symptomatology which bore a striking resemblance to that of certain myths and fairy stories: the magic key which opens the door to the secrets of life; the transformation of a weakling into a "Samson" with supernatural strength; an elaborate revival of the foster-parent phantasy; and the magical change of human beings into malignant insects. The cases showed the curious duality of the psychic life that was so universally observed in schizophrenic patients. On the one hand was the phantasy life; on the other, the normal personality with its memories intact and with a rational understanding of things in general. Another interesting feature of these cases was the relative coherence of the phenomenal experiences which surged into consciousness, in contrast with the fragmentary psychic productions in acute manic psychosis. The patient who observed that his visions were so vivid and real that it was just as if he were at the cinematograph aptly described the state of affairs in some cases. The phantasies of the schizophrenic are essentially dynamic and alive. *They expand, grow, and elaborate themselves.* The plot thickens and becomes more and more involved; and the players become more numerous. These generalisations in regard to the inner life of the schizophrenic might only be true for a certain number of cases, since "schizophrenia" and "dementia præcox" were wide terms, but Dr. Devine took the view that the inner life of the schizophrenic, even in long-standing cases, was often much richer than it would appear to be on the surface. He had made prolonged studies of individual cases to discover the drama which lay behind the mannerisms, neologisms, and fragmentary references made to "voices" and delusions. He held that a fundamental reason for the apparent incoherency of the psychic productions in many of our patients was that we are here dealing with affectively determined symbolic thought processes, the meaning of which could not be coherently stated by the patient. Though he did not hold any particular theory of dream psychology, he said, it was obvious that these psychic states must have a history (Freud), must have a bearing on current conflicts (Rivers), and, like all mental processes, they must reach out into the future (Jung). On the surface, the psychotic content in these cases exemplified the view of Rivers that a dream is the solution or attempted solution of an existing conflict. However this might be, it was evident that the psychotic content in these cases was symbolic in character. As the external world was shut off, the imagery, as in dreams, was naturally visual; there was, as it were, a silent interchange of thought without the use of verbal symbols.

Dr. Devine regretted the dearth of clinical investigation on the content of the psychoses, such as those of August Hoch. Hoch had shown that while an outside view of dementia præcox revealed an arbitrary array of manifestations, of delusions, hallucinations, queer notions, and an emotional condition often out of harmony with what the patient said, peculiar incoherent utterances, and bizarre acts—an analysis often showed that all these experiences mean something to the patient, that certain mechanisms are at work, and that there is, in these manifestations, a certain limitation to definite trends. The scattered and fragmentary speech gave an impression of incoherence because the connecting links were hidden from the observer.

Psychologically the consciousness of the schizophrenic was fuller than normal consciousness. The source of the psychotic symbolism was to be located in the conative-affective tendencies, the intellectual functions of many schizophrenics being remarkably unaffected. The development of definite psychotic material sometimes led to a cessation of tension, and was associated with a feeling of tranquillity and certainty such as the patient had not hitherto experienced. A study of the past history of these cases created the impression that the whole life had been emerging to its solution in the psychosis in an inevitable kind of way. When the delusion emerged doubt and uncertainty were dispelled; and as the patient looked back on his past life he felt that his delusion explained all to him that had been mysterious and strange. Evidently in some cases the psychosis expressed some fundamental need.

Schizophrenia was aptly described as a biogenetic psychosis, since its symptoms were manifested, not primarily in deterioration of the intellectual functions, but in disorders of the vital tendencies that were shared in common with all living creatures from the amœba upwards. In Dr. Devine's view, the importance of Freud's contribution to general psychiatry could be summed up in the fact that he deflected our attention from somewhat fruitless researches on the histology of the brain in this disease, which it was assumed would reveal its nature, and directed our attention to the organism itself and its biological cravings.

SCHIZOPHRENIA AS A HISTORICAL PROCESS

The psychiatrist saw the psychosis as the culmination of a series of events and processes, recent and remote, individual and racial, that had left behind indelible impressions upon the organism and were, indeed, part of its being. The psychosis could indeed only be interpreted as a historical process. The family traits, taints, indiscretions, illnesses; the psychic type; the endocrine pattern; the physique, organ inferiorities, dysplasias; the temperament; the tendency to pronounced fluctuations in the rhythm of the psychic processes—all these inborn peculiarities that not only predispose to a psychosis, but also determine its form and type, constituted the *hereditary unconscious.* The prenatal influences; the manner of birth; the family environment; the conditioning of the sexual life; the stresses, failures, life-wounds; the development of "faulty habits of reaction"; the bodily health—infections, septic foci, illnesses, unwise modes of living—all these factors which are liable to exert a baneful influence upon the psychic development constituted the *personal unconscious.* Thus historical events, both ancestral and personal, were condensed into the present and constituted the unconscious determinants of a psychosis. These unconscious determinants could be observed from the physiological standpoint.

Though no specific pathology of the disorder had been elucidated, the fact that it showed a prediction for the offspring of "tainted" heredity and of special constitutional types, could only mean that one or more physical "susceptibility" factors were in operation. One could assume that the concomitant metabolic peculiarities which had been discovered were significant of the physiological processes. It would seem probable that the reactions deviating from the normal had as their basis disturbances of one or more of the fundamental biochemical reactions of body, and especially of the central nervous system itself—changes, for instance, in tissue respiration and metabolism.

In the study of the problem which schizophrenia presents it was essential that we should cease to think of mind and body, but only of the living being and life. The problems of psychiatry were too deeply involved with disturbances of the physiological behaviour to enhance a purely psychological theory of the unconscious. For the psychiatrist the "unconscious" must include all the morbid processes, sequences, and changes revealed by objective methods of study, whether they be biochemical, histological, or psychological. The whole resources of medicine were required to solve the obscure problem of schizophrenia.

RECENT DEVELOPMENTS IN TREATMENT

In concluding his address, Dr. Devine referred to recent developments in the treatment of schizophrenia by pyrexial or shock therapy, which had met with some degree of success; by stimulation of the respiratory centre by intravenous injection of sodium cyanide; by cerebral stimulation produced by a mixture of carbon dioxide and oxygen. The most favourable and striking results from cerebral stimulation occurred in those patients who had been mute and inaccessible for long periods of time. A number of patients carried on conversations; one was markedly facetious and made remarks typical of talkative hebephrenic dementia præcox. Some of the patients appeared frightened when cerebral stimulation developed, but became calm and at ease when efforts were made to reassure them. The cerebral stimulation, as evidenced by free muscular movements, animated features, and ability to carry on a conversation and carry out requests, lasted from 2 to 25 minutes. After a variable period, the retrogressive changes began. Gradually, the voice became less audible; the response to questions became halting with long lapses; the facial expression became set; eye movements ceased; and attention could no longer be obtained. The muscular rigidity recurred. and in the course of two or three minutes the patient lapsed into his former state of mutism. negativism, and inaccessibility. Another recent method of treatment was the induction of a profound narcosis by injection of sodium amytal. Bleckwenn and others had obtained good results with intravenous injection of from grs. 10 to 15 of the drug. followed by daily intramuscular injections. Some patients awoke from the sleep thus induced in a more or less normal mental state, and remained so for a time, sometimes from 5 to 15 hours a day, during which they took their food, though having previously been negativistic and artificially fed. In the lucid intervals it had been found possible to elicit information from the patients which might have some bearing on the development of the psychosis.

Mlle. C. Pascal and her co-workers were also utilising chemical methods of stimulation in schizophrenic patients, using what she termed the "psycho-analytical pharmaco-dynamic" method. A variety of chemical stimulants were employed, either alone or in combination. These included: ether (inhalation); chloral hydrate of cocaine; sulphate of strychnine; hashish; mescaline; and nitrous oxide (inhalation). In certain cases music and songs had been utilised to amplify the psychosensorial excitation. When the stimulation was successful in breaking down the barrier of negativism, especially the mutism, an attempt was made to explore the psychic life and to penetrate the autism. The "analysis" was not strictly in accordance with the technique of psycho-analysis. The investigation was carried out by conversations patiently and firmly directed; association with dynamogenic words; the stimulation of emotional experiences by the presentation of such objects as photographs and letters; and sometimes by the evocation of traumatic experiences which stimulated strong affective reactions. No attempt was made to interpret symbols; this exploration of the psychic content was only intended to afford clinical information in a manner as objective as possible. In those patients in whom stimulation was successful it produced an altogether new psychic level. The most negativistic patients changed their affective attitude; they became amiable and polite, and the barrier of mutism and hostility fell like a mask. After the stimulant ceased to operate it had been possible in some patients to follow the psychic rhythm; the effort to maintain a state of equilibrium, the partial or complete check to reintegration, and the progressive or abrupt return to disintegration.

Though investigations such as these did something to satisfy the therapeutic impulse, their purpose was primarily intended to give precision to diagnosis and prognosis. The chemical stimulants serve to dissociate the reversible or functional lesions from those which are irreversible or structural. They reveal the dynamic possibilities of the schizophrenic patient. and separated the elements which are modifiable and unstable from those which are static and immovable. It was found possible to divide the patients treated by the pharmaco-dynamic method into five categories. Highest in the scale were the dynamic group with prevalence of reversible lesions; and lowest in the scale were the deficiency group with unmodifiable lesions. Between these groups were patients who exhibited, in varying degrees, the phenomena of life and death, the fragments of wealth and of destitution.

Though these researches were interesting and important, it could not be claimed that any notable advances in the treatment of schizophrenia had been achieved. Nearly 30 years ago Dromard had observed: "The precocious dement is a rich man whose capital is immobilised. Later he becomes a pauper." If this aphorism expressed a truth, and up to a point Dr. Devine believed that it did, it served to emphasise the urgent need of treatment and investigation in the very early stages of schizophrenia.

SECTION OF OTOLOGY

AT a meeting of this section on Nov. 4th, with MR. J. F. O'MALLEY, the President, in the chair, a discussion took place on the

Treatment of Lateral Sinus Thrombosis

MR. E. A. PETERS, in opening, reminded his hearers that the sigmoid sinus and the superior and inferior petrosal sinuses formed a triangle which drained the blood from the petrous bone. Following mastoid sepsis, small vessels might thrombose, and the clot might extend to the sinus and its connexions, causing a fatal diffluent thrombosis. Or the organisms from this zone—usually the hæmolytic streptococcus—might enter the blood stream and produce a bacteræmia, or, later, a septicæmia. There was the possibility, also, of the formation of a mural or parietal clot due to the sinus being surrounded by infected bone or by a perisinous abscess under pressure. Thrombosis due to endothelial inflammation from within was responsible for a more chronic form.

The common post-operative thrombosis of general surgery gave opportunities for prophylactic treatment, but that was not so in the acute cases under consideration. The mainstay in aural cases was incision of the membrana tympani early, eradication of the septic focus, and serum treatment. Arbuthnot Lane, in 1888, was the first in this country to open the sigmoid sinus. He emptied the sinus until he came to healthy clot, and then ligatured the internal jugular. The child recovered. The first to deal with the jugular bulb in a drastic manner was Grunert.

The primary and most important step in treatment was the eradication of the septic otitis. In all cases of acute mastoiditis the dura mater and lateral sinus should be exposed. In the presence of discoloration of the transparent blue wall, or a lack of pulsation, or the presence of clinical signs, the cavity should be mopped out with hot hydrogen peroxide, and needle puncture should be carried out. Where there was evident clotting the vein was excised and "bipp" on a plug was passed down to the bulb, but not experiences which surged into consciousness, in contrast with the fragmentary psychic productions in acute manic psychosis. The patient who observed that his visions were so vivid and real that it was just as if he were at the cinematograph aptly described the state of affairs in some cases. The phantasies of the schizophrenic are essentially dynamic and alive. They expand, grow, and elaborate themselves. The plot thickens and becomes more and more involved; and the players become more numerous. These generalisations in regard to the inner life of the schizophrenic might only be true for a certain number of cases, since "schizophrenia" and "dementia præcox" were wide terms, but Dr. Devine took the view that the inner life of the schizophrenic, even in long-standing cases, was often much richer than it would appear to be on the surface. He had made prolonged studies of individual cases to discover the drama which lay behind the mannerisms, neologisms, and fragmentary references made to "voices" and delusions. He held that a fundamental reason for the apparent incoherency of the psychic productions in many of our patients was that we are here dealing with affectively determined symbolic thought processes, the meaning of which could not be coherently stated by the patient. Though he did not hold any particular theory of dream psychology, he said, it was obvious that these psychic states must have a history (Freud), must have a bearing on current conflicts (Rivers), and, like all mental processes, they must reach out into the future (Jung). On the surface, the psychotic content in these cases exemplified the view of Rivers that a dream is the solution or attempted solution of an existing conflict. However this might be, it was evident that the psychotic content in these cases was symbolic in character. As the external world was shut off, the imagery, as in dreams, was naturally visual; there was, as it were, a silent interchange of thought without the use of verbal symbols.

Dr. Devine regretted the dearth of clinical investigation on the content of the psychoses, such as those of August Hoch. Hoch had shown that while an outside view of dementia præcox revealed an arbitrary array of manifestations, of delusions, hallucinations, queer notions, and an emotional condition often out of harmony with what the patient said, peculiar incoherent utterances, and bizarre acts—an analysis often showed that all these experiences mean something to the patient, that certain mechanisms are at work, and that there is, in these manifestations, a certain limitation to definite trends. The scattered and fragmentary speech gave an impression of incoherence because the connecting links were hidden from the observer.

Psychologically the consciousness of the schizophrenic was fuller than normal consciousness. The source of the psychotic symbolism was to be located in the conative-affective tendencies, the intellectual functions of many schizophrenics being remarkably unaffected. The development of definite psychotic material sometimes led to a cessation of tension, and was associated with a feeling of tranquillity and certainty such as the patient had not hitherto experienced. A study of the past history of these cases created the impression that the whole life had been emerging to its solution in the psychosis in an inevitable kind of way. When the delusion emerged doubt and uncertainty were dispelled; and as the patient looked back on his past life he felt that his delusion explained all to him that had been mysterious and strange. Evidently in some cases the psychosis expressed some fundamental need.

Schizophrenia was aptly described as a biogenetic psychosis, since its symptoms were manifested, not primarily in deterioration of the intellectual functions, but in disorders of the vital tendencies that were shared in common with all living creatures from the amœba upwards. In Dr. Devine's view, the importance of Freud's contribution to general psychiatry could be summed up in the fact that he deflected our attention from somewhat fruitless researches on the histology of the brain in this disease, which it was assumed would reveal its nature, and directed our attention to the organism itself and its biological cravings.

SCHIZOPHRENIA AS A HISTORICAL PROCESS

The psychiatrist saw the psychosis as the culmination of a series of events and processes, recent and remote, individual and racial, that had left behind indelible impressions upon the organism and were, indeed, part of its being. The psychosis could indeed only be interpreted as a historical process. The family traits, taints, indiscretions, illnesses; the psychic type; the endocrine pattern; the physique, organ inferiorities, dysplasias; the temperament; the tendency to pronounced fluctuations in the rhythm of the psychic processes—all these inborn peculiarities that not only predispose to a psychosis, but also determine its form and type, constituted the *hereditary unconscious*. The prenatal influences; the manner of birth; the family environment; the conditioning of the sexual life; the stresses, failures, life-wounds; the development of "faulty habits of reaction"; the bodily health—infections, septic foci, illnesses, unwise modes of living—all these factors which are liable to exert a baneful influence upon the psychic development constituted the *personal unconscious*. Thus historical events, both ancestral and personal, were condensed into the present and constituted the unconscious determinants of a psychosis. These unconscious determinants could be observed from the physiological standpoint.

Though no specific pathology of the disorder had been elucidated, the fact that it showed a prediction for the offspring of "tainted" heredity and of special constitutional types, could only mean that one or more physical "susceptibility" factors were in operation. One could assume that the concomitant metabolic peculiarities which had been discovered were significant of the physiological processes. It would seem probable that the reactions deviating from the normal had as their basis disturbances of one or more of the fundamental biochemical reactions of body, and especially of the central nervous system itself—changes, for instance, in tissue respiration and metabolism.

In the study of the problem which schizophrenia presents it was essential that we should cease to think of mind and body, but only of the living being and life. The problems of psychiatry were too deeply involved with disturbances of the physiological behaviour to enhance a purely psychological theory of the unconscious. For the psychiatrist the "unconscious" must include all the morbid processes, sequences, and changes revealed by objective methods of study, whether they be biochemical, histological, or psychological. The whole resources of medicine were required to solve the obscure problem of schizophrenia.

RECENT DEVELOPMENTS IN TREATMENT

In concluding his address, Dr. Devine referred to recent developments in the treatment of schizophrenia by pyrexial or shock therapy, which had met with some degree of success; by stimulation of the respiratory the floor of the tympanum. Cases of that kind were often diagnosed as aural bacteræmia. It should be widely known that mastoid tenderness might be absent in this disease; of the last ten cases of sinus thrombosis which he had seen only two showed mastoid tenderness.

Mr. F. HOLT DIGGLE (Manchester) said the vein was tied in fewer cases now than hitherto, because of treatment by sera and synthetic bactericides. It was not always necessary to expose the bulb, for it could be drained through a catheter whose end protruded from the neck. If a case was so severe as to require ligature, the vein should be tied at two points and the intervening portion should be removed.

Mr. ERIC WATSON-WILLIAMS (Bristol) said he could not see any objection to tying both jugular veins; he had several times done both within a week, and once he had tied them at the same sitting. Pulsation should be estimated by both view and touch; pulsation in a thrombosed sinus was more easily felt than seen, whereas in a sinus with blood in it, pulsation was more easily seen than felt.

LIVERPOOL MEDICAL INSTITUTION

Diabetic Lipæmia

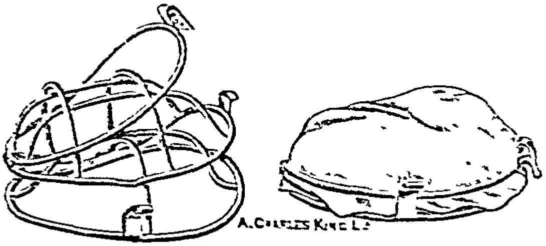
AT a meeting of this institution held on Oct. 27th, Prof. R. E. KELLY being in the chair, Dr. D. H. COLLINS summarised the clinical evidence of disordered fat-metabolism in diabetes, and discussed the types of lipoids in blood, and their relative significance in various conditions associated with high blood-fats. Evidence was given that diabetic lipæmia was endogenous in origin, as compared with the exogenous type following fat-feeding. Rückert's hæmolipokrit was described, and its reliability compared with the Schimidzu method of blood-fat estimation. The hæmolipokrit had the advantage of requiring neither special technique nor special apparatus, and only a small amount (0·15 c.cm.) of serum. Tables were shown giving the blood-fat readings taken by the hæmolipokrit in a series of cases. In 55 non-diabetics the average serum fats were 0·571 per cent. and in 103 diabetics under treatment, 0·818 per cent. There was an exaggeration of the lipæmia in cases with glycosuria, and a further increase in those with acetonuria. The following conclusions were reached: (1) that the more severe cases of diabetes as judged by other standards presented higher blood-fats; (2) that there was no parallelism between the variations of the sugar and of the fat content of the blood, and that the latter is more stable; and (3) that insulin when given in large amount decreased the blood-fat concentration. The opinions of other workers that a high fat content of the blood was of ill omen in diabetes was confirmed. A suggested explanation of the lipæmia in diabetes was that as the katabolism of carbohydrates was interfered with to a greater or less degree, so the mobilisation of fats was provoked in order to meet the calorific requirements of the body. Lipæmia was apparently a symptom of diabetes, which could be estimated and recorded, if additional guidance was required in diagnosis, prognosis, and treatment.

In the discussion which followed Dr. J. R. LOGAN said he had seen a case of fatal diabetic lipæmia in 1881, the first time the condition was diagnosed in the living. In this case, although there was an enormous amount of fat in the blood, the urgent symptoms terminating with coma had apparently only lasted about seven hours. How such a profound change could take place in so short a time was not easily explained even now.—Dr. E. CRONIN LOWE pointed out that there was a clinical value in knowing something more about fat metabolism in diabetes. Acetonuria, he said, was invariably associated with this increase in blood lipoids. Although in advanced cases, and those showing the presence of acetone in the urine, it would be of advantage to record any abnormal finding in the lipoid content of the blood, it was unlikely to be of clinical value in ordinary cases of diabetes.

NEW INVENTIONS

A MASK FOR USE WITH CHLOROFORM CAPSULES

CHLOROFORM capsules, as suggested by Mr. L. C. Rivett, have been used for some time in the second stage of labour at the Middlesex Hospital. The method of administration was to break one of the capsules, and to insert it into a Schimmelbusch mask in such a way that it lay between one of the cross-pieces of the mask and the lint covering. In practice this method has shown two drawbacks: (1) The chloroform evaporating in the intervals between the pains led to an uneconomic use of the capsules. (2) There was a danger of chloroform falling on to the face. In order to obviate these defects a Bellamy Gardner mask has been modified so as to interpose a layer of lint between the capsule and the patient's face. This mask was chosen as it is better adapted to fit the face in preference to the Schimmelbusch, which was devised for open administration of chloroform by the drop method. A small wire frame was made to go inside the mask, hinged to it on one side with a clip fastener on to the other. The wires constituting the dome of the mask were slightly cranked in order to give half an inch of clearance over the inner frame at its highest point, leaving a chamber for the chloroform capsule. To make up the mask two pieces of lint are taken, 8 by 6 in. One is placed in the original frame of the mask, a chloroform capsule is put in the inverted frame and broken. The second layer of lint is placed over this and the small frame closed, thus enclosing the capsule.



Mr. Leslie Williams has suggested [1] that the method may lead to overdosage owing to too concentrated a vapour being used. If, however, the mask is removed at the end of each pain and a new capsule is not inserted until the administrator is satisfied by placing the mask over his/her face that the vapour has become weak, then such an accident is outside the range of possibility. The mask has been made for me by A. Charles King, of Devonshire-street, W.1. The chloroform capsules are manufactured by Martindale and Co.

L. H. LERMAN, M.R.C.S. Eng.,
Senior Resident Anæsthetist, Middlesex Hospital.

---

[1] THE LANCET, Oct. 8th, p. 804.

tightly packed. This limited infection from the diseased area and prevented bleeding.

In the chronic mural cases the central part of the clot broke down into an abscess, and the latter ulcerated through the walls of the vein. Incision of this abscess and drainage should result in healing. When there was extensive clotting, the clot might extend down the internal jugular, and it was evidenced by swelling and tenderness along the vein, and a chain of swollen lymphatic glands. The veins in such a case must be exposed and excised.

In early cases of thrombosis of the lateral sinus the internal jugular vein was empty and collapsed, and it had the appearance of a white goose-quill. With the object of limiting infection along the inferior petrosal, the speaker packed gauze between the bone and dura mater, the latter being exposed by clearing away the cells anterior to the sigmoid sinus. It was dangerous to obliterate both lateral sinuses. Lymphatic isolation could be obtained by inserting gauze, where possible, between the infected bone and the dura mater. When an infected labyrinth endangered the meninges, this isolation could be carried to an extreme by separating the auditory and facial nerves from the internal auditory meatus—i.e., by inserting gauze and dissector between the bone and dura mater anterior to the sigmoid sinus after removing the sublabyrinthine cells.

Mr. W. F. WILSON (Newcastle) said that the treatment of septic thrombo-phlebitis of the lateral sinus and other complications of middle-ear suppuration had made great advances during the last 50 years. Zaufal had first suggested the operative treatment of sinus thrombosis in 1880. Nowadays, thanks to more exact knowledge of middle-ear disease and its complications, and thanks to post-graduate teaching, cases were treated in hospital without delay, and early treatment was found largely to obviate the grave complications. In lateral sinus thrombosis one was faced with not only an acute septic focus more or less completely walled in by a barrier of inflammatory tissue reacting to the infection, but an acute focus which had ingress to the whole systemic circulation via the internal jugular vein, superior vena cava, right heart, and lung. Therefore a very thorough mastoidectomy was called for, clearing out all septic bone and pus pockets, from the highest retrozygomatic gallery of cells to the tip of the mastoid below. Then the lateral sinus was laid bare by the careful use of chisel and gouge.

When there was doubt in the surgeon's mind as to whether the sinus was involved, the mastoid wound should be left wholly open, and a moist antiseptic dressing should be applied to the cavity to keep the skin margins apart, this being changed as often as necessary. This procedure not only permitted surface drainage but allowed of easy inspection of the wall, and, if need be, puncture or incision for diagnostic purposes. Where one could be fairly certain that the thrombosis was confined to a limited portion about the sigmoid area, many surgeons would be content to pack off the lower part of the sinus and clear out the clot until free bleeding took place, without tying the jugular vein. His own feeling was that ligation of the internal jugular vein should be done wherever the thrombus reached down to the bulb—whether the clot was mural or completely occluding—for otherwise disintegration of the thrombus might occur and cause a continued infection of the blood stream. Also, the vein should be tied in every case which presented active symptoms of pyæmia. According to many well-known otologists, both in this country and abroad, the complete operation on the bulb was as a rule unnecessary. It was a serious addition to the radical mastoid operation together with the clearing out of the sinus, and the facial nerve was frequently injured in the operation.

Mr. Wilson gave the results in 56 of his cases of lateral sinus thrombosis. A large proportion of his first group of 42 cases were admitted with a history of previous rigors, and with pyæmia or septicæmia. In the cases operated upon the usual procedure was to do an adequate mastoidectomy, with wide exposure of the sinus and a thorough clearance of the clot or other sinus contents, and the immediate control of bleeding by inserting "bipped" gauze between the sinus walls and the overlying bone, sometimes with ligation of the jugular vein. Of the 42 patients 22 recovered; in 5 there was no previous history of rigors. In a second group (14 cases) 9 were operated upon and all died; they were all very ill, and had either temporal lobe or cerebellar abscess, meningitis, and cavernous sinus thrombosis.

DISCUSSION

The PRESIDENT said it was important to emphasise in future text-books and in other ways that when a case had reached the stage in which there was tenderness or swelling of the jugular vein, death was almost inevitable. He agreed with Mr. Wilson that ligation of the vein should be carried out when the clot lay very low in the lateral sinus, for a clot in that situation might not drain readily through the open sinus.

Dr. DAN MCKENZIE said that his own policy was as follows: in easy cases in which the clot was accessible and could be removed entire, or almost so, the vein was not tied; in a grave case the vein was tied. But the problem was a difficult one.

Sir JAMES DUNDAS-GRANT pointed out that Macewen had remarkably good results in these cases without ligation of the vein, and he was a pioneer. This ligation was more an episode than the most important part of the operation; the exposure and treatment of the sigmoid sinus was much more vital.

Mr. T. B. LAYTON agreed with both openers that the chief part of the treatment of this condition was the complete removal of the septic focus in the bulb overlying the sinus; but he did not agree with their approach to the subject. The proper approach, he contended, was from the standpoint that thrombosis was a physiological process whereby Nature strove to prevent the invasion of the blood stream from the overlying osteitis, the rigors being regarded as evidence of a sudden and rapid infection by many organisms. In the operation he considered it was necessary to expose all the area of dura which naked-eye inspection showed to be diseased, carrying on until around the granulation area there was an area of normal dura.

Mr. SYDNEY SCOTT spoke of the value of the Queckenstedt-Tobey test—i.e., the reading of the cerebro-spinal pressure after lumbar puncture—as a means of diagnosis of lateral sinus thrombosis.

Mr. W. S. THACKER-NEVILLE (Darlington) argued the necessity, when doing a paracentesis, of carrying out a culture, and if this was septic, of opening the sinus. It was an important factor in prevention of grave sequelæ. If the patient had a temperature and the fluid showed hæmolytic streptococci he always opened the sinus.

Dr. DOUGLAS GUTHRIE (Edinburgh) said that in 500 consecutive cases of otitis in children, there were 80 of acute mastoiditis and only 2 of sinus thrombosis. A variety which deserved greater attention was primary thrombosis of the bulb; there was not then a clot within the sinus, but it was lower in the bulb, the infection having taken place through several of the well-designed charts and diagrams with which the book is illustrated. In a final section the commoner disorders of infancy and early childhood are briefly considered. Dr. John Fairbairn contributes a chapter on the maternity aspects of mothercraft, which in 21 pages provides a summary of the subject that is a model of its kind; Prof. John Mellanby on the Physiology of Lactation is less happy, in that his contribution would be more suitably placed in a book intended for general physiologists than in one for infant welfare workers. In referring to the book as a whole, in the course of a recent article (The Lancet, Oct. 1st, p. 745), we have commented on the meagre consideration given to the psychological aspects of mothercraft and the emotional relationship of mother and child. From the materialistic point of view we might add that the book would be of considerably greater value (especially to medical officers of infant welfare centres) if some space were allotted to the question of expense of the different feedings and articles of diet advocated. This might well take the place of the very detailed pages devoted to the immediate post-operative feeding of cases of pyloric stenosis, which in the great majority of cases is carried out in hospital. When these criticisms are made, however, the book remains one of real distinction and authority, which will be welcomed by all interested in the subject.

2. This small book contains the essay on Breast Feeding to which was awarded the Sir Charles Hastings Clinical Prize by the British Medical Association in 1932. The sentiments it expresses are unimpeachable. Dr. Housden rapidly convinces us that breast milk is the ideal food for babies, that infection is more liable to occur amongst the artificially fed, that an understanding of the normal baby is essential to a proper study of the art of medicine. From many of the case-histories and figures quoted, however, it is clear that even now this doctrine is not everywhere accepted, and we therefore hope the book will find its way to the unconverted. The technique of breast feeding and the commoner difficulties encountered are dealt with, and the book is profusely documented. We note that Dr. Housden believes in the hypodermic injection of expressed milk as a means of increasing breast secretion in difficult cases.

Materialism

By J. S. Haldane, Fellow of New College, Oxford; Honorary Professor, Birmingham University. London: Hodder and Stoughton, Ltd. 1932. Pp. 221. 3*s.* 6*d.*

Dr. Haldane has travelled a longish way in his philosophical pilgrimage since his Edinburgh days. He has not always been easy to follow; for by the time his readers had got some idea of what he meant in one of his books or essays he had moved further on himself and written another which did not say quite the same. But in the development of his faith there has been no inconsistency; its growth has been as coherent as his distinguished contributions to the details of physiology, and in this book of essays it seems to reach a mature expression which it has hardly achieved before, and a clarity in which some of his previous writings were, to some people, lacking. He began with the comparatively simple proposition that as a matter of experiment certain physiological processes, such as the uptake of oxygen by the blood, could not be explained, as some thought, by the known principles of chemistry and physics; this led to the argument that the working of the body cannot be dissected into its components because their sum is palpably less than the capacity of the whole organism; conscious behaviour is then brought into the field, and the something which is behind it, and finally the conclusion is reached, as a matter of experience, that the physical and spiritual worlds cannot be separated and that both find their reality in God—the "friend behind phenomena" of the Greek philosophers.

The eight essays of which the volume is made up were given as addresses on singularly diverse occasions —the opening of a medical school session, as president of the Institute of Mining Engineers, to the British Institute of Philosophical Studies, to the Liberal Jewish Synagogue, to the lunch-hour congregation at St. Martin's-in-the-Fields. The variety only emphasises his point that our experience is indivisible, and that all its items have a common background of spiritual reality. And thus Dr. Haldane moves, if we may say so, on to a level he has never reached before and preaches a religion of moving beauty and pursuasiveness, catholic in the widest sense. With theology and the systematics of organised religion he has little immediate concern; he indicates why he cannot give his personal adherence to any particularised creed or to any belief in a future life with rewards and penalties for what we do here. Let us realise, he says, that the physical world with which we are daily concerned, and about which it is so interesting and useful to find out all we can, is at best a very imperfect representation of reality. Those who have ears to hear will read the book with pleasure and advantage; those who have not will not understand what it is about, though even they will hardly grudge its modest price.

Manuel pratique de dermatologie

By A. Desaux and A. Boutelier. Paris: Masson et Cie. 1932. In 2 volumes. Pp. 1120. Fr.260.

This is a delightful book which presents dermatology in a comprehensive manner from the French angle. The authors belong to that famous St. Louis school which produced L. Brocq, Sabouraud, and Darrier, and others whose names stand for dermatological progress.

The first volume is divided into four parts. Part 1 gives general procedures, which include interrogation of the patient, examination of the stripped body in a good light, and a study of the elements of the eruption, its composition, and its localisation; these most useful "conseils" are followed by a brief section on the diagnosis of pruritus without visible cause. Ignoring for the moment Part 2, Part 3 deals also with diagnosis, that of the lesions presented, while the concluding section of the volume—Part 4—concerns itself with regional localisation and the assistance it can give to the investigator. The museum of the St. Louis Hospital supplies practically all the half-tone illustrations (none of them in colour), which greatly facilitate the study of Parts 3 and 4. They are numerous and exceedingly good, and the trained dermatologist will find many of them useful in comparing rarities of doubtful or differing nomenclature in the two languages. Coming to Part 2, this deals with the reactions of the skin, its anatomy and physiology (profusely illustrated by diagrams), its biochemistry, the mechanism of pigment formation, the immunising functions of the skin, the possibility of an internal secretion from it, its metabolism, the physiological connexions of the endocrine glands and the vegetative nervous system, and many other

REVIEWS AND NOTICES OF BOOKS

Dorland's Medical Dictionary

The American Illustrated Medical Dictionary. Sixteenth edition. By W. A. NEWMAN DORLAND, M.D., F.A.C.S., with the collaboration of E. C. L. MILLER, M.D. London: W. B. Saunders Co., Ltd. 1932. Pp. 1493. 35*s.*; or with thumb index, 37*s.* 6*d.*

IN reviewing the fourteenth edition of this work five years ago we alluded to the tendency for a dictionary in later life to become an encyclopædia. We received the fifteenth edition but failed to review it, owing to a fruitless search for omissions of which only three ultimately came to light—namely, Higginson's syringe, prolan, and solipsism. One of these is made good in the sixteenth edition now before us which, we are told, contains several hundred new words, most of which appear for the first time in any dictionary. The encyclopædic tendency has now resulted in the inclusion of 279 portraits of men who have given their names to the terminology of medicine. These portraits, many of them borrowed from Garrison, constitute a gallery of the great physicians of the past. They are excellently reproduced, and there is no doubt that they do enhance the interest of the volume, especially for the odd moments when the reader idly turns over the pages. From the artistic point of view the portraits suffer from their proximity to pictures of monstrous fœtuses and patients suffering from unattractive diseases, but this perhaps is inevitable. If now converted to the use of text illustrations we are still sceptical of the value of such plates as that of biliary calculi (between pages 228 and 229) which fill so scantily two whole leaves of a book, otherwise a masterpiece of legible compression. In this edition the terminology of physical therapy has been brought into harmony with the suggestions of the Council on Physical Therapy of the American Medical Association, and the whole book has been through the hands of the staff of the Association under the direction of Dr. Morris Fishbein. It is now 32 years since Dorland's dictionary began to appear, and during this time the volume has continuously improved in appearance and in ease of reference.

A Text-book of Pathology

An Introduction to Medicine. By WILLIAM BOYD, M.D., M.R.C.P. Edin., F.R.C.P. Lond., Professor of Pathology, University of Manitoba; Pathologist to the Winnipeg General Hospital. London: Henry Kimpton. 1932. Pp. 946. 45*s.*

THE medical student has already the choice of many excellent text-books of pathology, and the first reaction aroused by a new production is a guess as to its fate in competition with its established rivals. We predict that Prof. Boyd's text-book will enjoy a considerable degree of popularity, for it is a pleasantly written and readable work, is well illustrated, and covers the ground quite adequately. Its motive is the study of pathology in relation to the living patient, and it is intended to serve as an introduction to medicine and surgery. Wherever possible the author strives to correlate clinical symptoms with pathological lesions, and to this end in his description of the more important diseases an account of the lesions is preceded by a brief summary of the clinical symptoms, and followed by a discussion on the relation of symptoms to lesions.

The book is essentially a student's manual for, as Prof. Boyd points out in his preface, it is no longer possible to write a text-book for the student which shall at the same time serve as a book of reference for the working pathologist. Brevity and a somewhat dogmatic attitude are prime virtues in students' text-books, and Prof. Boyd has wisely resisted the temptation to discuss theories in too great detail. But brevity and dogmatism may be carried to excess, as they are occasionally here. For example, the section on pneumoconiosis is so brief as to be misleading, and the bald statement that acute diffuse glomerulo-nephritis is an indication of bacterial infection would be improved by a little elaboration. It was a pleasure to find on page 35 a warning against a teleological view of inflammation for, as the author says, "there is nothing transcendental about the process, which is governed by purely physico-chemical laws and must not be looked upon as purposive in nature." It was the more disappointing therefore to read on page 232 that "cancer is a process unlike any other biological process. All other processes are designed to an end. Growth, reproduction, inflammation, repair, all have meaning. Cancer apparently has none." But in the main Prof. Boyd follows his own counsel and avoids teleological argument. His teaching is sound and thoroughly up to date, and excellent descriptions of recent work, for example that on the origin of the melanomata, are included.

1. Mothercraft, Antenatal and Postnatal

By R. C. JEWESBURY, D.M. Oxf., F.R.C.P. Lond., Physician in Charge of the Children's Department, St. Thomas's Hospital; Hon. Medical Director to the Mothercraft Training Society. London: J. and A. Churchill. 1932. Pp. 178. 10*s.* 6*d.*

2. The Breast-fed Baby in General Practice

By LESLIE GEORGE HOUSDEN, M.B., B.S. Lond. London: H. K. Lewis and Co., Ltd. 1932. Pp. 118. 4*s.* 6*d.*

1. FEW pædiatricians could be better qualified than Dr. Jewesbury to write on the subject of infant feeding and management. This book represents the fruit of 25 years' experience of infant welfare work and of close association with the Mothercraft Training Society since its inception. Breast feeding, it need hardly be said, is strongly and consistently advocated, and full consideration is given to its establishment and maintenance. The principles of artificial feeding on the "percentage" system, initiated by Sir Frederick Truby King, of which the author has been the principal exponent in this country, are given in detail. This method, of which the aim is to keep constant the protein ratio (the percentage of calories derived from protein to those derived from fat and carbohydrate), and of limiting the total protein given to 1·6 per cent., involves a somewhat elaborate modification of cow's milk by dilution and addition of both fat and carbohydrate. Dr. Jewesbury recommends the use of lime water also in formulas made up with raw cow's milk. Whether this complexity of ritual is entirely necessary or even practicable in dealing with normal infants of the out-patient class is open to question, and there are those who will hardly agree with the author's emphatic statement that "protein indigestion is one of the commonest difficulties met with in bottle-fed babies." There is no question, however, that percentage feeding can, and does, give very satisfactory results, and if confirmation of this were needed it would be found in

Antiphlogistine

BRAND

DRESSING

spread thickly from ear to ear and from chin to sternum and covered with cotton-wool and a tight bandage, is a tested method for relieving the pain and inflammation of acute laryngitis. Due to its thermogenic potency and to its bacteriostatic action, Antiphlogistine Dressing induces an active hyperaemia in the affected area, which dilates and flushes the superficial capillaries, stimulates leucocytosis and promotes the destruction of the bacteria.

Acute Laryngitis

Sample and literature will be sent upon request to

THE DENVER CHEMICAL MFG. CO.
LONDON, E. 3.

considerations. A brief chapter on the common affections of the nail-bed and the pilosebaceous follicle are followed by a dissertation on the general principles of local treatment, rules, and the indications for hydro-, physio-, helio-, and electro-therapy. The authors have handled this chapter, as indeed they have the whole book, in a novel and stimulating way. The well-illustrated chapter on cosmetic surgery, which is perhaps more practised in Paris than elsewhere, is contributed by Pierre Brocq.

The second volume includes a description of the dermatoses—eczema and its numerous types, psoriasis, and the parakeratotic group. Then follows a chapter on the protozoal infections, including syphilis, which is very briefly discussed in comparison to other dermatological conditions. The mycological, superficial and deep, the microbial, and ultramicroscopic infections are then discussed, special attention being devoted to leprosy and tuberculosis of the skin, and finally—and this is an original feature—a 200-page illustrated "dictionary" of the dermatoses, classified in alphabetical order, and liberally annotated with diagnostic and therapeutic aids is supplied.

The industry, care, and knowledge that have been expended in the preparation, illustration, and the entirely novel arrangement of this excellent text-book deserve high commendation.

A Text-book of Clinical Neurology

Second edition, revised. By ISRAEL S. WECHSLER, M.D., Professor of Clinical Neurology, Columbia University, Philadelphia. London: W. B. Saunders Co., Ltd. 1932. Pp. 759. 35*s.*

THIS work appeared originally five years ago, during which period some notable advances have been made in knowledge of the diseases of the nervous system. These have been incorporated by Prof. Wechsler in his second edition, which in several ways represents an improvement on its predecessor. The scientific caution of the writer is well exemplified by his brief critical review of such questions as the syndromes of the corpus striatum, the ætiology of the neuroses, or the relation of the endocrines to nervous function. On the other hand, as befits a book for students and practitioners, the presentation of the accepted facts of clinical neurology is dogmatic, descriptive, and concise. The illustrations are more or less uniformly good. Brief bibliographies are appended to each section.

Technique of Ultra-violet Radiology

By D. T. HARRIS, M.B., B.S., D.Sc., F.Inst.P., Professor of Physiology, London Hospital Medical College. London: Blackie and Son. 1932. Pp. 166. 6*s.*

THIS small volume, one of Blackie's Technique Series, was designed by Dr. Harris to meet the needs of workers who wish to handle ultra-violet generators for any purpose. It fulfils a want, giving in clear concise form the laws governing radiation, absorption, generation of ultra-violet radiation by high-frequency oscillatory discharges, arc lamps, and mercury-vapour lamps. The methods used in detection and measurement of ultra-violet radiation are indicated. There is a useful chapter on spectrometry; others deal with thermal radiometers, photo-electric methods, and amplification. A short section on ultra-violet therapy contains in condensed form a wealth of useful information. The book is clearly illustrated, and contains useful diagrams and tables. It may be doubted, in spite of the suggestion printed on the loose cover, whether the book will prove of value to nurses, laboratory workers, and medical students. The subject matter precludes easy reading, and some knowledge of advanced physics is necessary if the reader is to follow Dr. Harris's account of the laws governing ultra-violet radiation.

The book will appeal, however, to the specialist, the research worker or technician, and to the bio-physicist, for the information it summarises is not easily accessible.

Surgical Pathology of the Female Generative Organs

By ARTHUR E. HERTZLER, M.D., Professor of Surgery, University of Kansas. London: J. B. Lippincott. 1932. Pp. 346. 21*s.*

THIS monograph forms one of a series on the branches of surgical pathology; thus many of the topics are dealt with from the point of view of the general surgeon rather than of the gynæcologist, who will be disappointed by the lack of detail in certain places. The views expressed, however, are shrewd and sound. The condemnation of unnecessary operation and indiscriminate oöphorectomy is welcome, particularly when expressed with such vigour. The descriptions call for little criticism. A welcome innovation is the inclusion of an account of the pathology of retained products of conception in the section dealing with non-malignant diseases of the uterus. The references are derived almost entirely from American publications, and compare unfavourably as indications of important work with those usually supplied in modern text-books. The book is beautifully produced, and the illustrations are worth careful study, and surgeons who deal with all types of abdominal surgery will find it of considerable value, though it is hardly the exhaustive treatise on gynæcological pathology which such a controversial subject seems to demand.

The Legal and Ethical Aspects of Medical Quackery

By LEONARD LE MARCHANT MINTY, Ph.D., B.Sc., LL.B. London: William Heinemann (Medical Books) Ltd. 1932. Pp. 262. 7*s.* 6*d.*

THIS is a valuable little book. It is written without exaggeration and the author's statements are supported by full reference to legal procedures and decisions, and publications in journals, lay and medical. The mere list of legal cases cited occupies some three pages, and in many cases the notes on what happened justify fully the author's statements. An introductory chapter on "Infamous Conduct in a Professional Respect" is a lucid description of a subject which is eternally puzzling to those who do not understand either the origin of the unfortunate phraseology or the dependent penal procedure. We wish that critics of the General Medical Council could read this chapter before making appearances in print. From the chapters on the herbalist, the bone-setter, and the osteopath, the reader should learn what chances these rivals to the trained medical man have of effecting anything which is beyond the powers of qualified medicine, while the risks to the public of confidence in the unqualified are set out. But there is no intolerance in the author's views, and in many places he recognises the value of the proceedings undertaken by unqualified persons, while they are working in a position ancillary to scientific medicine.

THE LANCET

LONDON: SATURDAY, NOVEMBER 12, 1932

SERUM TREATMENT OF POLIOMYELITIS

LAST March we published a report by Dr. JEAN MACNAMARA and Dr. F. G. MORGAN on the serum treatment of poliomyelitis in Melbourne. The conclusion of this report was that the disease could often be diagnosed in its pre-paralytic stage and that "the use of human immune serum at this stage, in adequate dosage, has given excellent results as evidenced by a low mortality-rate, a low average total paralysis, and a strikingly low proportion of paralysis of the severer grades." These conclusions have been challenged on the ground that the controls provided were insufficient. About the same time S. D. KRAMER, W. L. AYCOCK, and their associates,[1] in the United States, described a series of 82 cases in which roughly half received serum in the pre-paralytic stage and no reason was found to suppose that it did any good. The same conclusion was reached in a large inquiry made in New York at the suggestion of Prof. W. H. PARK, whose results have already been summarised in THE LANCET (July 23rd, p. 186). It is agreed that the only way to prove the worth of the serum would be to treat alternate cases with it. This has not been done of late years, for the usual reason that believers in the remedy cannot see their way to withhold it. Attempts to provide controls in other ways are full of difficulties. For instance, a campaign in favour of early treatment by serum —such as the campaign in Melbourne—introduces a fallacy because it leads to the recognition of cases which would otherwise not have been diagnosed. A high proportion (variously estimated) of patients with poliomyelitis do not develop paralysis, whether treated or not. Under ordinary circumstances they are apt to escape diagnosis; but if a great effort is made to secure serum treatment of every patient most of these minor cases will be brought to hospital; and the end-results, on the average, will appear to be very much better than usual. The successes of MACNAMARA and MORGAN are criticised on these lines, and the general opinion at the annual meeting of the American Medical Association last summer was that the investigations of PARK, and of KRAMER and AYCOCK, more nearly approached a controlled experiment than any others so far made. The provisional conclusion was that further work should be done, but that nothing favourable has been proved. PARK[2] points out that poliomyelitis is a virus disease and that we have no knowledge of any such disease that can be benefited by an antiserum after clinical symptoms have developed. This does not, of course, mean that serum is inactive; indeed, in the valuable reference book[3] just issued under the auspices of the International Committee for the Study of Infantile Paralysis, of which Prof. PARK is chairman, evidence is given of the value of serum for the passive immunisation of children during an epidemic. But prophylactic and curative value are not synonymous, and we have the example of measles before us in which convalescent serum is a definite preventive in the early stages of the incubation period but is impotent after illness has begun.

The facts are thus sub judice; but many workers are convinced by their observations that serum is clinically useful in the pre-paralytic stage of poliomyelitis, and there is little reason to think it can be harmful if properly given. Hence there is naturally a demand both from medical practitioners and from the public for its administration in individual cases. In this country the treatment is in use in London County Council hospitals, at Oxford, at Manchester, and elsewhere. The Ministry of Health, we understand, are watching the results with close interest and an immunisation committee has been set up at the Ministry which keeps in close touch with this work and also with research which is in progress. In practice it should be realised that, on present evidence, treatment by convalescent human serum is only to be given in the pre-paralytic stage; according to most authorities it is of no avail when paralysis has once supervened. The clinical diagnosis should if possible be confirmed by an examination of the cerebro-spinal fluid made at the bedside without delay and the procedure described by MACNAMARA and MORGAN may here be followed with advantage. Although lumbar puncture, by itself, has often been recommended as useful in poliomyelitis there is now some reason to suppose that it may actually initiate involvement of the central nervous system by drainage of spinal fluid, through permitting readier penetration of the virus through the choroid plexus (J. E. GORDON). Hence some hold it unwise to remove cerebro-spinal fluid and to delay the administration of serum while that fluid is sent away for examination—as was done in the New York investigation. For diagnostic purposes, however, 5 c.cm. of cerebro-spinal fluid suffices and the examination can be carried out quickly if the microscope and counting-chamber are ready for use before the lumbar puncture needle is inserted. By this means a second lumbar puncture may be avoided if intrathecal administration is employed.

The collection and preparation of serum requires special precautions and the supply from convalescents is necessarily limited. A recent study by MAURICE BRODIE[4] in Canada, however, confirms previous statements that serum of high antibody content may be found in urban adults who are not convalescent from the disease, and his figures suggest that serum from this source is

form of treatment for the specialist rather than for the general dental practitioner. "Prevention of periodontitis for the community, as distinct from the individual under expert care, is as yet non-existent and the outlook is frankly pessimistic." In the final paper of the series Dr. R. G. Agnew reminds us that pyorrhœa is by no means confined to civilised man. He has visited some of the primitive races living in the Himalayas whose diet is almost exclusively maize, supplemented by a few vegetables. He found that the mouths were so dirty that he had to remove mounds of corn-meal from the teeth in order to examine them. Caries was almost non-existent but, by contrast, pyorrhœa was common. In observations like this, which are now rapidly accumulating, there must surely be clues that will enable us before very long to fit the parts of the puzzle together. Despite Dr. Box's warning against optimism—and it would undoubtedly be echoed by most authorities to-day—it is hard to believe in the impossibility of devising some effective and relatively simple scheme of dental prophylaxis.

THE DOCTOR'S DAY

"Happy the people whose annals are blank in history's pages" is a saying attributed to Montesquieu; the sentiment is inverted by modern phrasing in the journalistic proverb, "Bad news is good copy." It is for this reason that there is little contemporary record of the doctor's life—how it is he lives and what it is he does. The "bad news," in other words the lurid happenings, do occur, but not with the frequency that morbid or romantic fancy suggests; and when they do occur, while they would furnish material for popular excitement, they are often exactly the events which cannot be recorded, for this or that reason, in a public manner. The seamy side of professional life, it is true, is presented unostentatiously at the board meetings of medical protection societies, and is briefly delineated in certain annual reports; while the adventures of those who have to appear before the General Medical Council in various circumstances may figure prominently in the lay press. These things have what is called "news value," and their appreciation is raised by their rarity. They are the sensational or sordid things which the more credulous seem to hold make up the doctor's day. When Dr. Jekyll is accompanied by Mr. Hyde he secures a notoriety which he and his colleagues regret, but the notoriety is out of all proportion to the significance of the occurrences, and is enhanced by their rarity. Every doctor, it is true, must be prepared for a plunge into drama, just as he must be prepared to meet a clinical emergency. On any day he may be involved in a legal suit, with issues of high "news value," or be confronted with the need to make a decision upon which life will depend. These things are sporadic not epidemic in the professional diary, and receive generous attention. But the working day escapes record to such an extent that few doctors know how their confrères along different lines of activity spend their day. To describe in detail the life of the doctor, either generally or along its various professional objectives, has been hardly attempted; the sympathetic studies of Scott, Trollope, and George Eliot are not forgotten, but serve to show how difficult it is to tell the story from without. On another page appears the first of a series of articles entitled "The Doctor's Day," contributed upon invitation by practitioners in various walks of medicine—an attempt to write the story from within. The articles are written, it will soon be seen, on no uniform plan, the authors recording their personal experiences, and preserving anonymity. For the information of those who like a tale to have a cheerful message we may disclose the fact that, speaking generally, the contributors to the series have found themselves happy in their lot.

UNEMPLOYMENT AND HEALTH

This week has seen a parliamentary debate on unemployment and the issue of a final report by the Unemployment Insurance Commission. The political issues are once more before the Government and the country. But as year follows year many people are becoming convinced that no political solution will be adequate—that the future of industrial society depends less on schemes of payment than on the adjustment of minds. A social revolution is in rapid progress; the time has gone when anyone can justifiably feel that men who are out of work have only themselves to blame, and the time has come when everyone must reconsider his responsibility towards them. On these matters of ethics the medical profession may be supposed to have nothing to say—a view which, we are glad to think, is not universally held; but where physical and mental health is in question medicine is deeply concerned. The special contribution should here be the supply of accurate information. It is being stated, for example, by untrained observers that malnutrition is becoming widespread in town and country, and it is important that the public, as well as the Government, should have the evidence of trained observers by which to judge this opinion. Is this evidence as readily available as it should be? In the Commission's report it is stated as a fresh principle of the Bill of 1924 "that an honest man shall not starve though he be unemployed," and the Blanesburgh Committee said that ideal benefits should be sufficient to prevent the insured man from being haunted by the fear of what must happen to him if he is unemployed. The present scheme was not intended (p. 190) to provide complete subsistence, and the Minority Report of the Commission quotes (p. 377) the feeling of responsible people that "benefit is now failing to maintain families adequately even at a bare maintenance level." Is this true?

The new home of the British College of Obstetricians and Gynæcologists, 58, Queen Anne-street, London, W., will be formally opened by H.R.H. the Duchess of York on Monday, Dec. 5th, at 3 P.M., and in the evening of the same day a dinner of the College will be held at Grosvenor House, Park-lane. The President of the College, Prof. Blair Bell, will preside at the opening ceremony and the dinner. Fellows and Members who wish to be present at either should apply for tickets at once to the Hon. Sec., 58, Queen Anne-street, London, W.

equally effective; certainly it is very much more easily obtainable and therefore should be cheaper. As regards technique, it is thought that the best clinical results are obtained by intrathecal and intravenous administration. The dosage is regulated by the age of the patient, but it is desirable to give as large a dose as possible; an average dose is 20 c.cm. of convalescent serum intrathecally with 30 c.cm. intravenously (R. W. Fairbrother). If no sign of improvement is observed the dose should be repeated every 24 hours until improvement occurs. Macnamara and Morgan give an average dose of about 60 c.cm. intrathecally at first. The serum should be warmed to 37° C. and it should be given slowly and by the gravity method after withdrawal of a larger amount of cerebro-spinal fluid. A second intravenous dose or even a third may be necessary if the response to the first is not immediate.

The international committee's new book on poliomyelitis shows how tremendous is the mass of information about this disease already collected. The problems of its epidemiology, prophylaxis, and specific remedies are bewildering, and it is a relief to turn to branches of practice whose principles are clearly laid down. It is hard to speak too strongly of the importance of caring for paralysed limbs from the very outset of the illness, and the ways in which this may be done are set out in our present issue by Mr. Alan Todd.

◆

PREVENTIVE DENTISTRY

This year, for the first time, the British Dental Association held its annual meeting outside Great Britain, and the proceedings of the Toronto Congress, fully reported in the October issue of the *British Dental Journal*, are likely to be long remembered with satisfaction. The symposium on preventive dentistry is, perhaps, of special interest, both in revealing the present state of our knowledge and in indicating the trend of thought in this country and in America. The first paper on preventive orthodontics, by Dr. Martin Dewey, of New York, shows how this branch is growing, and while still concerned with the treatment of irregularities of the teeth, is actively engaged in the more important task of trying to prevent them. The implications of preventive orthodontics go far beyond æsthetics, for it is recognised that irregularities of the teeth predispose to dental caries and pyorrhœa. Dewey divides the causes of malocclusion into three groups—inherited, congenital, and acquired. Some of the congenital factors can be controlled. The most important is malnutrition, and here he lays great stress on nourishment of the mother during pregnancy. Preventive orthodontics begins before the birth of the child, and the real task of the orthodontist in this connexion is, he thinks, to educate the medical profession. Malocclusion, he holds, is a disease of civilisation, because civilisation has produced food fashions which make mastication unpopular and unnecessary. This lessening of the function of the jaws is reflected in impairment of growth, and even if a vigorous habit of mastication be adopted in later life, this cannot compensate for the invaluable stimulus of use while the permanent teeth are developing and the growth of the jaws is most active. Another factor of much importance in the prevention of malocclusion is normal nasal breathing. Mouth-breathing, he believes, is becoming much commoner and brings about a series of harmful results in gums, jaws, and teeth. Finally, the early treatment of malocclusion—while the deciduous dentition is alone affected—falls properly into the category of preventive orthodontics, since at this time the treatment is relatively simple and will prevent deformity of the permanent teeth. All malocclusions are progressive and none of them is self-corrective.

The second paper, on the prevention of dental caries, was by Mr. A. E. Rowlett, who represented England in the symposium; it is a thoughtful presentation of a subject singularly complex. There are three main ways in which caries might be preventable: (1) by the resistance of the teeth themselves, which is another way of saying that the structure of the teeth is the all-important factor; (2) by the action of the saliva combined with a diet rich in detergent elements, and, conversely, poor in the sticky, fermentable carbohydrates; and (3) possibly by lessening the activity of the acid-forming bacteria of the mouth. Rowlett points out that the protagonists of these three schools of thought can all claim a good deal of experimental and clinical evidence in support of their views. But so far, he thinks, it is impossible to say decisively that any one method can be relied upon to prevent caries. Of particular interest is his account of peoples living under primitive conditions and possessing a natural immunity to dental decay. But, he remarks, while the solution of the problem may lie in the absence of caries in the inhabitants of Tristan da Cunha, the multiplicity of factors involved makes it impossible to assess their individual value. "It does not help us that theorist after theorist may declare that the perfect teeth of the islanders is proof of his own particular contention." At present, he believes, all methods which appear to offer means of preventing caries must be adopted, but as yet there is no certain and easy method of avoiding it.

Writing on the prevention of periodontitis (pyorrhœa), Dr. Harold Box, of Toronto, whose researches on this disease have done so much to elucidate its pathology, is less hopeful in tone. He reviews the present state of our knowledge, and concludes that the most important ætiological factor is an abnormal occlusion of the teeth which leads to a state of strain on the supporting tissues. This faulty occlusion, according to Box, is of relatively modern onset, and is correlated with changes in dietetic habits and an alteration from an edge-to-edge occlusion to an overlapping one. The prevention of periodontitis, according to this view, lies chiefly in the restoration of a balanced occlusion. Something can be done by the dentist to bring this about, but it is, in Box's opinion, a method also the diaphragm is raised by pressure of the abdominal viscera, in this case effected by direct pressure applied to the small of the back.) Dr. Eve reports the trial of his method on the normal subject, and in one case of post-diphtheritic paralysis and one of Landry's paralysis. It will be of interest to see if his expectations are justified by further clinical investigation of the method, which has the great advantage that a minimum of apparatus is required, and this can be rapidly extemporised. The possible regurgitation and inhalation of stomach contents is a danger which might in practice prove insurmountable. Another method in which the diaphragm is raised and lowered by alteration in the pressure of the abdominal contents has been described by Dr. Rudolf Eisenmenger in a recent lecture to the Society of Physicians in Vienna.[1] The apparatus, which he graphically describes as "The Biomotor," consists of a flexible shield across the concave surface of which is stretched a rubber diaphragm; the convex surface is connected with two electric motors by means of which air can be driven into, or sucked out of, the shield. The rubber diaphragm is closely applied to the upper abdomen and lower part of the anterior chest wall of the patient, so that the abdominal wall is alternately sucked outward and compressed. In this way, the patient's diaphragm is rhythmically lowered and raised. The speed and depth of respiration can be varied at will, and the author claims that the apparatus, in addition to providing artificial respiration, serves to aid the circulation of blood which is driven from the liver and splanchnic region towards the heart.

UNIVERSITY OF DURHAM: NEWCASTLE COLLEGE OF MEDICINE

THE publication of certain facts in connexion with an inquiry into the administration of the Newcastle College of Medicine has revealed two things: first, that any detailed comment on the situation would be certainly inexpedient and possibly unfair, while all that has happened is sub judice; and secondly, that there can be no reason why the inquiry should be delayed in face of the resolution of the Court of Governors of the College in its favour. There is superabundant evidence of the need for the inquiry, and it is evident that the College may suffer by the prolongation of the existing situation. The medical profession has a strong interest in a right settlement of the important points at issue; the general constitution of the College of Medicine indicates this. The governors—elected, contributory and representative—number 128, mainly non-medical and non-university members, while the executive council consists of 28 members, of whom 11 are medical; 9, including persons who may be medical, are representatives of the Court of Governors, the rest represent Armstrong College and other sections of the University. The controlling body of the College has had within it a powerful medical section, and to the medical profession at large the reasons should be made clear how and why the present state of affairs has come about. This does not mean that virtue lies in the publishing of disputes where personalities are freely employed; but it does mean that the medical public should know what has caused a serious cleavage of opinion among those responsible for the medical school of a university. Lord Londonderry, as Chancellor of the University of Durham, with the pertinent evidence before him, has said that an independent inquiry should be instituted into the administration and constitution of the college of medicine of the University; the governors of the College, by a large majority, have found the Chancellor right. There seems no reason for delay in the consequent procedure.

GALL-STONES

THE recent international congress at Vichy[1] discussed the major problems of biliary calculus and its sequels. The tone of many of the papers read revealed a new spirit of caution, contrasting with the extremely active attitude towards gall-stones predominant a few years ago. Precision in diagnosis rendered possible by the introduction of cholecystography has contributed to this change. Time was, as R. Gilbert (Geneva) pointed out, when the surgeon had his knife into the gall-bladder which filled adequately but emptied with "pathological" slowness. Failure to fill or inadequate (mottled) filling are now demanded as the real evidences of disease. Dr. Gilbert claims that even in cases with chronic jaundice cholecystography may give the required clue. On the biochemical side, N. Fiessinger (Paris) and J. Dieryck (Louvain) had to admit that the laboratories are not yet able to give much assistance. Deeply interesting and technically adroit though their work has been during the last decade, chemists are still unable to assess the extent of damage to the liver in jaundiced cases, or, when jaundice is not present, to offer much help in diagnosis or treatment. Dieryck summarises his conclusions thus:

> (1) Investigation of biliary function does not give precise information on the importance of the lesions of the hepatic parenchyma and does not allow a clinical prognosis to be made.
>
> (2) Investigation of the nitrogenous function necessitates a delicate technique and leaves a good number of cases of "slight hepatitis" undetected.
>
> (3) Investigation of the excretory function of the liver is not indicated in this affection.
>
> (4) At the moment one cannot judge the state of the liver either by the study of the antitoxic function or by the metabolic disturbances of the lipoids.
>
> (5) Investigation of the glycogenic function by production of galactosuria and the study of the total and partial concentrations of galactose eliminated, allows the state of the liver to be revealed and its gravity to be appreciated. Besides this, it distinguishes a mechanical jaundice (obstruction of the bile-ducts) from a hepatic jaundice (due to cellular disease).

Turning to pathogenesis, no one can yet assert with conviction that the origin of biliary calculus is exactly understood, but it is worthy of note that throughout this congress there was little if any dissent from the present-day doctrine that (1) disease of the walls of the gall-bladder is an invariable accompaniment of cholelithiasis, and that (2) many examples of the disease are complicated by a serious degree of hepatitis, which may not only increase the hazards of operation but will itself require treatment even when the gall-bladder and its contents have been removed. So many speakers emphasised this latter point that it is only fair to point out that the predominance of hepatic complications is the natural result of an ultra-conservative attitude towards surgical treatment. While the surgery of the biliary tract must never be lightly attempted, when expert help is available it becomes a grievous mistake to permit repeated attacks of colic or jaundice before the surgeon is called in. It would not be right to state the matter so strongly without adding that it is just the attack of colic or of jaundice that justifies surgical intervention. J. V. Donnet (New York) uttered a

ANNOTATIONS

PYELITIS IN PREGNANCY

The dilatation of the upper urinary tract which is associated with pyelitis of pregnancy has long been known, and several explanations of its cause have been suggested. Opitz attributed the dilatation to compression of the ureter between the uterus and structures at the pelvic brim. Stoeckel drew attention to the atony of the ureter which sometimes produced dilatation throughout its entire length. Hofbauer believed that muscular hypertrophy of the lower end of the ureter and its sheath caused obstruction. Dr. Dugald Baird, in the Bradshaw lecture which we published last week, lays stress on atony as the primary factor. Dilatation of the ureters begins, he says, in very early pregnancy before the uterus is large enough to cause compression at the pelvic brim. Obstruction is a secondary factor and is first seen at the fourth or fifth month; it is usually most marked on the right side, the site of compression being the pelvic brim. The muscular hypertrophy noticed by Hofbauer is very slight at this stage of pregnancy and is more probably a protective reaction, developed only in the later months.

The cause of the atony, Dr. Baird suggests, is probably an endocrine disturbance, possibly deficiency in the posterior pituitary secretion. Ovarian cysts also cause dilatation of the ureters and renal pelvis, but this dilatation is never so great as that which occurs in pregnancy and the ureter is not dilated below the pelvic brim. Anselmino, Hoffman, and Kennedy have shown that there is an over-production of the posterior pituitary hormone in patients with toxæmia, and these patients never show atony of the urinary tract, and do not develop pyelitis. The atony and stasis are associated with a delay in excretion which can be demonstrated by renal function tests. Baird found dilatation present in 62 per cent. of primigravidæ and 42 per cent. of multiparæ in a series of 100 normal patients examined at monthly intervals. Previous estimates give widely differing figures, both above and below this. In a series of 96 patients who had sterile urine when first seen, 14·5 per cent. showed pus and organisms later in pregnancy. This may be compared with the results of an investigation of 406 unselected patients by Gladys H. Dodds.[1] She found that 11·2 per cent. developed bacilluria during pregnancy, but in only 7·6 per cent. was the organism *Bacillus coli*. Infection of the urinary tract is therefore a common complication of pregnancy. It sometimes gives rise to symptoms which may be diagnosed as due to albuminuric toxæmia; it is sometimes associated with hyperemesis, and occasionally with uterine hæmorrhage. Microscopical examination of the urine should always be done as a routine measure in the diagnosis of any toxæmia of pregnancy, for the typical symptoms of pyelitis are often absent. The source of the infection is not discussed in Dr. Baird's lecture. The condition is usually considered to be a descending infection, due to the excretion by the kidney of bacilli circulating in the blood. The bacilli probably come from the colon and would not be able to infect a normal urinary tract. Constipation, which is commonly present in cases of pyelitis, is probably the cause of the absorption of an abnormal number of bacilli. A paper by H. F. Helmholz[2] on spontaneous pyelitis in the rabbit suggests an ascending infection for this type of pyelitis. The rarity of post-mortem examinations in pyelitis of pregnancy makes it difficult to come to a final conclusion.

The routine treatment of pyelitis by alkalis, followed by acid sodium phosphate and hexamine when the temperature has been normal for a week, is only partly successful; but postural treatment, designed to relieve pressure at the pelvic brim, is remarkably effective in some patients who are resistant to treatment with alkalis alone. Dr. Baird suggests a complete urological examination including catheterisation of the ureter. Ureteric catheters may be left in, and the drainage of the renal pelvis which follows will often determine the subsidence of acute symptoms. The problem of cure is more difficult. Treatment of pyelitis by a ketogenic diet after the acute stage is over has given better results than the older treatment by acid sodium phosphate. If the urine can be maintained at a pH of 4·6 to 5·0, growth of the colon bacillus is inhibited and the urine becomes sterile. This method, which is still in the experimental stage, may become the routine treatment of the future.

PROLONGED ARTIFICIAL RESPIRATION

The recent occurrence in this country of a number of cases of anterior poliomyelitis giving rise to respiratory paralysis has emphasised the importance of having available methods of artificial respiration which can be carried out over periods of many hours or days. Although the course of the bulbar type of paralysis (a form of the disease which is fortunately rare) is unlikely to be permanently benefited by artificial respiration, there are cases in which the diaphragm or intercostal muscles are affected where the procedure may be a life-saving one if respiration can be maintained until some recovery of the paralysed muscles has taken place. In all types of case the patient's distress is likely to be very greatly relieved. Manual methods (of which the Schafer is far the most satisfactory) have the great advantage of being immediately available and readily applied. They are usually without danger, though damage has been done by a heavy operator applying pressure to a patient with broken ribs, and a number of deaths from ruptured liver have occurred from the use of Howard's method. Even a team of trained operators, however, can hardly apply these methods for more than a limited number of hours, and for intractable cases mechanical methods become desirable. The older methods of pumping and sucking air directly into or out of the lungs have been generally abandoned owing to the large number of deaths which occurred from rupture of the lungs or stomach. Nowadays the lungs are made to fill and deflate rhythmically, by applying negative or positive pressure to the outside of the abdomen or thorax. The use of the Drinker respirator in poliomyelitis, carbon monoxide poisoning, and asphyxia neonatorum has been described and discussed on several occasions in our columns, most recently a fortnight ago; and since then reports of its use at the Wingfield Orthopædic Hospital, Oxford, confirm again the fact that it offers a most efficient method of applying artificial respiration over long periods. In our last issue Dr. F. C. Eve described a method of using gravity for actuating a flaccid diaphragm. The patient is laid prone on a trestle which is seesawed about its mid-point; the weight of the abdominal viscera serves to raise and lower the diaphragm with resulting filling and emptying of the lungs. (It may be pointed out that in the Schafer heeded. Whatever the operation and however small the risk may appear, constant care is essential. There is a species of legal action to which he did not refer, which is threatened in a blackmailing attempt to evade the payment of fees. Threats of this kind seem to be on the increase.

MODERN AIDS TO ANÆSTHESIA

OPENING the first meeting of the session, the new President of the Section of Anæsthetics of the Royal Society of Medicine, Dr. Charles Hadfield, passed in review the modern aids to anæsthesia. Paraldehyde, avertin, the barbiturates, and carbon dioxide naturally formed the basis for most of his comments, which were catholic and judicious. He did not touch on local analgesics or on methods of administration. The present aids at our disposal, in the form of what are called basal narcotics, excellent as they are, still leave room for improvement. Dr. Hadfield pointed out, giving illustrative cases, that some of them are not free from danger, and others are not entirely dependable in their action. Dr. Hadfield regarded avertin as probably the most popular of these drugs at present, and expressed surprise that paraldehyde, the first of them to be employed and still perhaps the safest, is not more widely used. He alluded to cases of intestinal atony occurring after avertin and after other basal narcotics in which he believed these drugs could not be entirely exonerated, and called attention to the risks of a multiplication of preliminary drugs administered to any patient.

Several speakers testified to the good results they had obtained by following nembutal with chloroform, but one mentioned a case in which this combination of drugs, although given only in small doses, had resulted in a sleep which lasted for three days. Dr. Hadfield raised the question of the true nature of narcosis from nitrous oxide, relating interesting examples of the recurrence of mental impressions made during the unconsciousness due to this agent.

ALUM-TOXOID AS AN IMMUNISING REAGENT

AMONG the more important recent developments in active immunisation against diphtheria has been the introduction of toxoid treated with alum. So far the use of this material has passed little beyond the stage of animal experiment, but the valuable report of Dr. J. C. Saunders on p. 1047 brings the possibility of its routine use in human immunisation a step forward. A. T. Glenny's claim that alum-toxoid (A.M.T.) is an immunising agent of exceptional potency has been abundantly confirmed by almost all subsequent workers. It is fairly clear that the secret of its efficiency lies in the fact that the alum-toxoid complex is removed very slowly from the site of its introduction, and the animal is thus submitted for a long time to a continuous antigenic stimulus. A similar explanation serves to explain the superior antigenic properties of other preparations that are poorly absorbed, such as toxoid-antitoxin floccules and the toxoid-tapioca mixtures of Ramon. A certain amount of human immunisation has already been carried out with alum-toxoid by the workers of the Wellcome Research Laboratories, by Park and Schroder in New York, and by Wells, Graham, and Havens in Alabama, and the results of these trials are in agreement with Dr. Saunders's opinion about the high antigenic efficiency of the new preparation in human immunisation. But not all those who have taken part in the trial of the reagent have been equally satisfied with the reactions which follow its injection. There seems to be a distinct tendency for the material to produce rather obstinate indurations, and occasionally even cold abscesses, and these effects, if not very alarming, put it, in its present form, at a disadvantage as compared with some of the older and better tried prophylactic reagents. Dr. Saunders gives no details of the actual reactions he met with, but he clearly implies that the reactions were not very serious, and that they gave him little administrative difficulty. This apparent discrepancy between his observations and those of others may perhaps be due to the fact that he practises in the Irish Free State where smallpox vaccination is really compulsory, and where the population is possibly more hardened to the minor inconveniences of immunising procedures. In this country it has been a steadfast principle of the laboratory workers responsible for making diphtheria prophylactics that immunising power, always allowing that it is adequate for practical ends, must take second place to considerations of public safety and even of public comfort. Thus the anomalous situation has arisen more than once in recent years, of foreign immunologists adopting extensively the use of a new prophylactic devised in an English serum laboratory, while it is still being tried with the greatest circumspection in its country of origin. We cannot but praise our serum laboratories for their forbearance in refusing to pluck the fruit of their own growing, which lies so temptingly to their hand. It is just this forbearance which has made England a safe country to be immunised in. "Insoluble" antigens such as alum-toxoid represent an important step forward in immunising science, but the time is probably not yet ripe when such material should be released for routine use.

INFANT LIFE PROTECTION

AN important object of the Children Act, 1908, was to put a stop to the evils of baby-farming, and to a large extent it has been successful. Part V. of the Children and Young Persons Act, 1932, and the second and fourth schedules to the Act, which will come into operation on Jan. 1st, 1933, are designed still further to tighten up the regulations governing infant life protection. The Minister of Health has addressed to the London County Council and to maternity and child welfare authorities outside London a circular and a memorandum [1] setting out the powers and duties included in this part of the Act, together with a suggested form of advertisement for use by councils, and a leaflet of advice to foster-parents. A second memorandum, containing a summary of the statutory provisions, is intended for the use of infant protection visitors. Substantial alterations of the existing law have been made :—

> The age under which reception of children for reward must be notified has been raised from 7 to 9 years. Instead of notifying the reception of a child within 48 hours, the foster parent must now notify it, with full particulars—
>
> (*a*) In the case of a first child not less than seven days before reception.
>
> (*b*) In the case of any other child not less than 48 hours before reception.
>
> (*c*) In the case of a child already received without reward, within 48 hours after the undertaking to receive for reward.
>
> Change of residence must also be notified to the authority at least seven days before removal, or, in case of emergency, within 48 hours after, and the death of a child, or its removal from the care of a foster-parent must be reported both to the authority and to the person from whom the child was received within 24 hours.

The Minister's statement that reports received by him suggest a lack of knowledge of the regulations serious warning to those who would too lightly remove the gall-bladder; experimental removal of the gall-bladder, he said, is always followed by dilatation of the biliary channels, with progressive fibrosis and degeneration of their walls. H. Béclère (Paris) gave a vivid picture of the effect of cholecystectomy on neighbouring organs:

---

[1] Circular 1291. Memo. 165/M.C.W. 2*d*. Memo. 165A M.C.W. 1*d*. November, 1932. H.M. Stationery Office.

> In many cases, he said, distress continues after cholecystectomy and new disturbances may appear. Radiological examination may reveal the character of fistulous tracts, and sometimes calculi or a bit of drainage-tube remaining in the lower portion of the common duct. Radiography, preceded by radioscopy, may show lesions of perivisceritis, so frequently following ablation of the gall-bladder. The duodenal bulb is always deformed after cholecystectomy. In the presence of identical deformities, distress occurs in some cases, while in others it may be absent. Perivisceritis may not be limited to simple deformity of the bulb; apical difficulty, imprisonment of air-bubbles, and version or torsion of the bulb may exist. Difficulty in the upper bend (*superior genu*) occurs fairly frequently and secondary folding or bending of the bulb may be produced. The deformity of the bulb rather commonly has the so-called "bucket" aspect, which shows the presence of embarrassment, sometimes accompanied by rather severe pain. Stenosis when more highly developed may require supplementary operation; section of adhesions or gastro-enterostomy. Adhesions may also occur at the second portion of the duodenum, presenting certain characteristic deformities in the radiogram. The right colon may be surrounded by or embedded in the mass of adhesions present. When the abdomen is suddenly hollowed by an abrupt movement, the organs lying about the duodenal centre are displaced in a single mass. These various lesions compose the painful consequences of cholecystectomy.

If, then, there are good reasons for surgical intervention in many cases of gall-bladder disease, there are equally good reasons for the exercise of the highest skill in the selection of appropriate cases. While it may be true enough that the patient who has been operated on for biliary colic will remain the surgeon's friend, the patient who is operated on between attacks of jaundice has really stronger reasons for gratitude; but the surgeon who operates on patients in whom gall-stones have provided nothing more alarming than dyspepsia is creating for himself just so many potential critics.

THE RISKS OF SPECIALIST PRACTICE

Mr. Musgrave Woodman's presidential address on the Throat Surgeon and the Law, delivered on Nov. 4th before the Laryngological Section of the Royal Society of Medicine, was not confined to the discussion of problems affecting only the specialist but covered most of the legal risks to which the whole profession are subject. He gave first a summary of the legal position in which the surgeon specialist is placed, pointing out that the performance of a specified operation is in law a matter of contract. The patient, if conscious, must consent before any operation, whether great or small, is carried out. If, as the operation proceeds, some more extensive surgery is required, the surgeon will not be held liable for exceeding the limits of consent in order to save life; but the burden of proof lies on the surgeon. It is prudent to have a responsible relative within call to give consent when required. Patients should be warned beforehand if the likelihood of any important extension is foreseen. Performance of the wrong operation is not a negligible risk; a safeguard for preventing such a mistake is to read the notes of the case or a special operation card immediately before the operation. Another possible source of legal action is the use of methods which go beyond the accepted practice of the day; here the eighteenth-century case of Baker, senior surgeon to St. Bartholomew's Hospital, remains as a warning. Analysing the degrees of negligence, civil and criminal, the duty of skill (varying with the status of the practitioner) and the duty of care, Mr. Woodman dealt also with responsibility for the acts and omissions of assistants, presumably introduced by the surgeon himself, and of nurses and attendants, as illustrated by hot-water bottle cases. The obligation of secrecy received due attention; special mention was made of the difficulty where an employer sends a workman to the surgeon and, having paid the consultation fee, expects to be told all about the man's condition. Mr. Woodman suggests the examination of such patients in the presence of the employer where possible, otherwise to refer the employer to the patient for information. Turning from the purely legal to the practical hazards, Mr. Woodman touched on such diverse incidents as prosecutions under the Road Traffic Act (the smell of ether, he remarks, may readily be mistaken for alcohol by a constable), the careless use of radium, and the accidental dislodgement of a tooth while a gag is being applied to the mouth. He cautions the surgeon to expect less mercy over a tooth dropped into the lung than the dentist will receive whose duty it is to remove the tooth intentionally. A peril of rhinological practice is to leave ribbon gauze packing in the flaps of the nasal septum, in the antrum, or high up in the nose. Careful search should always be made to see that no foreign bodies have been left behind. A swab in the mouth or pharynx should have a silk thread leading out of the mouth; gauze in the nose should have an end hanging out over the lip. The septum operation has two pitfalls. One is depression at the junction of the cartilaginous and bony portion of the bridge; if this occurs, it is a profound mistake to belittle the result to the patient. To prevent a possibly heavy claim for damages Mr. Woodman's counsel is that a female patient in particular should be told that, if she is dissatisfied with the shape of her nose, it shall be made into any shape she wishes by the grafting of cartilage without further fee. Perforation of the septum (the other great danger) must also be taken seriously; otherwise, if the patient drifts into the hands of another practitioner who quite innocently draws attention to it, a legal action may follow. Then there is the possible mischance of damage to the facial nerve in mastoid operations; if it is more than a simple operation, it is well worth while to warn the patient in advance of this serious contingency. Lastly, Mr. Woodman mentions the anxieties associated with diathermy and anæsthesia, and the question of explosions. In diathermy, he said, the surgeon is well advised to employ a skilled electrician to relieve himself of responsibility for serious variations in the intensity of the current; burns, which result if the electrode touches some part not under treatment, may be actionable injuries. The respective responsibilities of surgeon and anæsthetist have never been clearly established. The surgeon chooses the anæsthetist and is answerable for his skill and care but not for his actions in administering the anæsthetic; but the general supremacy of the surgeon in the operating theatre attracts to him a corresponding liability. As for explosions, Mr. Woodman believes most of them to be attributable to badly constructed electric bulbs introduced into the mouth or bronchus. Ether vapour, relatively non-inflammable in concentration, is highly explosive when well diluted with air; oxygen converts a simple explosion into a detonation; in the most serious cases the flame appears to flash up the anæsthetic tube and the apparatus is blown up, with resultant injuries to patient and surgeon so grave that no amount of precaution can be deemed excessive. Mr. Woodman's warning should be well

SPECIAL ARTICLES

MEDICINE AND THE LAW

Alleged Exploitation of Patients

IN London and elsewhere where local Acts have so provided, a licence is required before an "establishment for massage or special treatment" can be carried on. Acting under its statutory powers the Public Control Committee of the L.C.C. on Oct. 28th refused to grant Edward William Barton-Wright a licence for an establishment at 6, Campden House-terrace, W.8. The applicant has for some years carried on an establishment at this address under licence, but objection was now taken on the ground that he had extracted large sums of money from his patients, the greater part of which he had apparently made no attempt to repay. It was stated that he had been three times adjudicated a bankrupt—in 1893, 1910, and 1932, with liabilities totalling approximately £8000 in all, and assets nil—and had not yet applied for his discharge. The chief officer of the Public Control Department based his objection to the applicant upon the following three cases. In 1924 a patient named Evans had been persuaded to lend £3500 on the security of a debenture in a company; this debt had not been settled. In 1929 another patient was approached with a view to his guaranteeing a sum of £400 towards the cost of leasing a shipbuilding yard at Warren Point in Ireland. The patient lent £400 on the assurance that it would be returned within eight days. It was not returned; solicitors were instructed, and Mr. Barton-Wright was stated to have disappeared from his lodgings. Judgment was obtained, but the sheriff's officer discovered that there were no personal effects. The patient said that only £61 had been repaid; he understood that Mr. Barton-Wright had seven or eight patients at 25 guineas a week. A third patient, a lady living at Holland Park, said she was persuaded to lend £1200 in 1929 in return for a debenture in a company; this was to be repaid within a year or two years. It was suggested to her that she should become secretary to a company called Nature Treatments, Ltd. She had been repaid only two instalments of £100 each, and it was on her petition that the applicant was recently adjudicated bankrupt again. Mr. Barton-Wright, in support of his application, said he had repaid the lady £375, including interest. He attributed his first bankruptcy to a conspiracy. He had always intended to pay back the various sums he had borrowed, but his creditors were cutting their own throats by attempting to prevent his obtaining a licence to carry on his establishment. He claimed to be a specialist in arthritis. His present troubles were due to an illness caused by his experimenting upon himself with a new cure for arthritis.

The grounds on which the L.C.C. can refuse a licence, stated in its General Powers Act of 1920, do not differ from similar provisions elsewhere—for instance, in the Surrey County Council Act of last year. A licence may be refused if the applicant is under age or "unsuitable to hold such a licence"—a phrase conveying wide discretionary powers. It may also be refused where the premises are unsuitable or the provision for treatment is inadequate or where the establishment has been or is improperly conducted, or where the massage or other curative treatment is administered by someone who "does not possess such technical qualifications as may be reasonably necessary." The Act does not apply to public hospitals and similar institutions or to establishments carried on by registered medical practitioners, subject to certain conditions. An applicant aggrieved by refusal may appeal to a metropolitan police magistrate and thence to quarter sessions. The 1920 General Powers Act superseded similar provisions in a General Powers Act of 1915 on the ground that the previous law had been found "insufficient for the prevention of immorality." There was, of course, no suggestion either of immorality or of technical incompetence against Mr. Barton-Wright in the recent proceedings. The gravamen of the allegations against him was that he exploited elderly and infirm patients by persuading them to part with their money. It is not difficult to imagine the view which would be taken if similar allegations were established against a registered medical practitioner in his relations with his patients.

What is "Sickness"?

The Court of Appeal has affirmed the Divisional Court in holding that the word "sickness" in a wages agreement includes any circumstances which prevent a workman from carrying out his work and thus includes incapacity due to accident. A grocer's assistant was employed under an agreement containing a clause giving three weeks' wages during "periods of sickness." He injured his thumb and claimed under the agreement; his employers admitted liability under the Workmen's Compensation Act, but denied that the word "sickness" in the agreement included accident. The county court judge said that, if the agreement had been meant to cover incapacity due to injury from accident, it was inconceivable that it would not have said so expressly. The Divisional Court interpreted sickness as any morbid condition, irrespective of its cause. The Court of Appeal said sickness was in plain language an ailment which prevented one from being in perfect health. Sickness benefit in State insurance covers benefit paid for disablement as well as for disease. When, observed Lord Justice Scrutton, the marriage service prescribes the obligation to cherish "in sickness and in health," no one contemplates an added reservation "but not in the case of accident."

A Priest's Refusal to Answer

Recent discussions on medical secrecy add interest to a case before the Nottingham magistrates (reported in the *Justice of the Peace*) about a month ago, where a Roman Catholic priest declined to answer a question which was possibly most material for the purpose of the proceedings then before the bench. A girl had taken out an affiliation summons against the putative father of her child. The priest was asked questions concerning a conversation he had had with the parties in his church vestry. It is easy to understand that the answer to such questions, presumably involving solid evidence as to admission or denial of paternity, might well have been conclusive in a disputed case. The witness declined to answer. He said he considered it his duty to maintain the sacred trust reposed in him even at the risk of a possible miscarriage of justice. The bench expressed the opinion that the refusal amounted to contempt of the court but it wisely took no action. The case was disposed of by an order made on the strength of other evidence available. Legally there are technicalities depending on the nature of the court concerned. Some courts are "courts of record"; others are not. If a contempt is committed in the face of a court of governing infant life protection among authorities and their staffs seems to imply that evasion can and does occur. Sir George Newman pointed out in his last annual report that "the responsibilities of infant life protection are not confined to dealing with cases actually notified, but include the admittedly difficult task of ascertaining, and of having notified those cases which so far have evaded the law." Authorities are advised to issue advertisements warning foster-parents that children must not be taken for reward without previous notification, and inviting them to apply to the council for further particulars. Section 68 makes it an offence to publish any advertisement of persons or societies willing to receive children under 9 unless the advertiser gives name and address. In London a full-time officer is employed entirely in scrutinising such advertisements.

Except in London infant protection visiting is now usually carried out by health visitors, and under the new Act the supervisory duties have been extended to include the general health and well-being of the children. One task of the infant protection visitor is to recommend suitable homes for registration. The demand for good foster-mothers is far greater than the supply, and the temptation must be strong to accept homes which fall below the desired standard. Great caution, however, should be exercised both in recommending homes and in granting exemption from inspection; there is always a danger of the development of homes of an unsatisfactory nature under cover of the phrase "convalescent home" or "boarding school," unless care is taken to limit the number of children that may be received in any dwelling. New power is given to impose conditions to be complied with where the total children kept in the dwelling exceed a certain number. Another means of evasion is to assert that a child has been adopted, and here again every case should be investigated and the legal adoption verified. No doubt the law that is knave-proof has yet to be enacted; recently a scoutmaster and Sunday school teacher was fined for proved cruelty to a child which he had received without reward. But these changes and others under the new Act are designed for the safeguarding of a peculiarly helpless group of children. It is clearly desirable that the officers concerned with its administration should familiarise themselves with the whole law of infant life protection without delay.

EARLY IMPRESSIONS OF CHLOROFORM CAPSULES

A SYMPOSIUM of opinion on the relief of pain in normal labour, contributed to the October and November issues of *Maternity and Child Welfare*, contains some early impressions of the value of the 20 ♏ chloroform capsules which are now being distributed for trial to hospitals and medical men.[1] Miss E. M. Pye, president of the Midwives Institute, finds that even this very small quantity of chloroform makes the mother less sensitive to pain, prevents her from inhibiting voluntary efforts, and enables her to sleep between pains. Dr. J. S. Fairbairn believes it to be incumbent on the medical profession to work out some means of giving analgesia that can be used by the midwife and will suffice to ease the final pangs of childbirth without interfering with normal parturition and without risk to mother and fœtus, and therefore welcomes a full trial of the capsules. Mr. L. C. Rivett from his experience regards this method as safe and foolproof, and trusts that before long it will be available to all midwives who gain a certificate of proficiency in its use. Miss M. M. Cashmore, sister-matron of the British Hospital for Mothers and Babies, as a result of an admittedly short trial, believes that the capsules, used in combination with a general sedative, will prove a real means of diminishing pain. Dr. Rhoda Adamson, after a longer experience, considers that the capsules gave a definite degree of subjective help to the patient, but were insufficient to allow as deliberate a delivery as can be obtained with inhalation anæsthesia given by the drop method. On the other hand she had no doubt of the advantage of chloroform capsules at the time of delivery when the alternative was no relief at all. Less favourable opinions were given by Dr. Edith Phelps and Dr. J. M. Oldaker. The former feared that even the degree of chloroform analgesia promoted by the capsules might cause delay in delivery, and make it difficult for the midwife to leave one patient to attend to others; while Dr. Oldaker, alone of those contributing to the symposium, has found the capsules unsatisfactory except at the beginning of the second stage. In her experience, gained when resident anæsthetist at the obstetric unit of the Royal Free Hospital, she found that the state of light anæsthesia produced renders the patient excitable and unruly when the head is being born, so that coöperation with the accoucheur is impossible. Moreover, she has found it extremely difficult, with the 20 ♏ available, to get the patient beyond this unruly stage.

This symposium makes a good beginning to the investigations which are being promoted by the National Birthday Trust Fund. The varied opinions at least lend no support to the view that such a small dose can be no more than a placebo.

A Royal medal of the Royal Society has been awarded to Dr. Edward Mellanby, F.R.S., professor of pharmacology in the University of Sheffield and physician to the Sheffield Royal Infirmary, for his work on dietary factors, especially in connexion with rickets. The Society has awarded its Buchanan medal to Prof. T. Madsen, director of the State Serum Institute at Copenhagen, for his theoretical and practical work on immunity, especially in relation to diphtheria antitoxin. At the anniversary meeting on Nov. 30th, Sir Gowland Hopkins, M.D., will be recommended for re-election as president, and Sir Henry Dale, M.D., as one of the secretaries. Recommendations for the council include the names of Dr. J. A. Arkwright, Prof. A. V. Hill, Prof. E. Mellanby, and Mr. Wilfred Trotter.

THE Thomas Vicary lecture will be delivered by Mr. Francis Weston, F.S.A., next Tuesday, Nov. 15th, at 5 o'clock at the Royal College of Surgeons of England, Lincoln's Inn Fields, London, W.C. The foundation of this lecture is interesting. Thomas Vicary was Serjeant Surgeon to King Henry VIII and Master of the Barber Chirurgeons. In 1919 the Barbers' Company undertook to provide an annual sum of ten guineas every five years for the purpose of instituting at the college an historical lecture in anatomy or surgery, to be called the Thomas Vicary lecture, the appointment of the lecturer being left to the discretion of the college. In 1923 and again in 1930 the Barbers' Company renewed the donation. Sir John Tweedy was the first lecturer. Mr. Weston proposes in his lecture to tell of the London Guild of Barbers which incorporated the Barber Chirurgeons. Tickets of admission are not required.

---

[1] See THE LANCET, Nov. 5th, p. 1024.

nature of mass-movement of dry or moist, warm or cold air, he demonstrated statistical data, proving that certain diseases are most prevalent at certain seasons of the year. It is well known that most of the infectious diseases of childhood reach their highest incidence in winter time; the same holds good, he believes, for the acute catarrhs of the upper air passages, for tetanic conditions, for eclampsia, hemiplegia, and even for ulceration of the duodenum and stomach. Prof. de Rudder distinguishes here between "climatic diseases" and "weather diseases." Some observers attribute the variations in the incidence of certain morbid conditions to variations of barometric, thermometric, or hygroscopic conditions of the air. Prof. de Rudder believes that to be due to changes of the electromagnetic condition of the atmosphere—i.e., to the effect of short-wave radiation. He suggests that when rheumatic subjects feel a change of weather conditions 24 to 36 hours before the actual change takes place they are feeling radiations from the approaching air masses. Prof. Moll discussed the therapeutic value of changes in climate. The children requiring "change of air" included anæmic, easily exhausted children, rather nervous, with little appetite, or with signs of late rickets, and those with chronic catarrhal affections of the air passages, and swollen glands. The first group were benefited by a prolonged stay at an altitude of 2000 to 4000 feet; the second group obtained more advantage from a stay at the seaside. These deductions had been drawn from observations on nearly 30,000 children, and the contra-indications to certain climates had also been learned. Patients with active disease of the lungs, with nephritis, acute and chronic arthritis, otitis media, and cardiac disorders were not, in Prof. Moll's view, fit for the seaside; tuberculosis of the bones and joints and glands obtained most benefit from higher altitudes (4000–6000 feet). A very important therapeutic factor was change of surroundings and of food.

INFANT PROTECTION CONFERENCE

In conjunction with this meeting the Deutsche Vereinigung für Saüglings und Kleinkinderschutz held its fifth convention on the following day, Prof. Roff (Berlin) presiding. The proceedings were devoted solely to the subject of tuberculosis, and four reports were presented. Prof. Hamburger (Vienna) spoke on the effect of heredity, natural resistance, and immunity upon the course of tuberculosis in children. He pointed out that in taking the history of the child one must also investigate all cases of infantile tuberculosis in the patient's family, not only that of the adults. The natural resistance against the tubercle bacillus being very inconstant, the time of first infection must be carefully sought; therefore he lays stress on a regular tuberculin test by Pirquet's method or by the percutan way, performed twice yearly on all not yet infected children. In the discussion Dr. Mommsen (Lübeck) reported on the fate of the surviving infants from the disaster at Lübeck. They were frail, suffered from intestinal troubles and anæmia, but showed no signs of primary tuberculosis. He believed that those who died received either a stronger dose or had a special disposition to infection.

Prof. Spitz (Mayence) discussed the expectation of healing of manifest tuberculosis in children. The earliest possible recognition of the infection was essential if a cure was to be obtained. At present over 25 per cent. of the cases coming to the sanatorium were brought too late. Prof. Spitz held that, especially girls of 8 to 10 years, if they were exposed to an infectious focus, should be examined regularly by X rays.

Prof. Langer (Berlin) pointed out that tuberculosis of the bronchial glands should receive great attention. A negative X ray picture was not sufficient. A searching clinical examination was necessary to ascertain whether or not the child was infected.

Prof. Duken (Jena) discussed whether the infected child should be sent to a health resort or a sanatorium. He believed that such children might regain health under their mother's care if properly supervised by the general practitioner. In opposition to this standpoint the Vienna school (Moll and Götzl especially) held that, not only the infected child, but even those endangered by their surroundings should be sent away. The congress supported this view.

IRELAND

(FROM OUR OWN CORRESPONDENT)

MILK LEGISLATION

In the Dáil last week Sir James Craig drew attention to the delay in introducing a Clean Milk Bill; clean milk being, he said, of vital importance to the State. The Minister for Local Government and Public Health, in reply, said that he hoped at an early date to put a proposal before the House and to promote legislation. The delay in dealing with the milk question is a discredit to both parties which have been in power during the last few years. Early in 1928 a commission on the milk-supply completed its report, suggesting legislation on certain lines, and it was promised that a Bill would soon be introduced. In July, 1929, the lines of the proposed measure were stated to the House, but, despite repeated questioning by Sir James Craig and others, no progress has since been made. The truth is that the agricultural interest is too strong on both sides of the House for any Government to find it easy to promote legislation which is likely either to increase the trouble or diminish the profits of milk-producers.

THE CARE OF THE ILLEGITIMATE CHILD

The problem of the care of the illegitimate child appears to be becoming more serious than formerly in the Irish Free State. Addressing a meeting of the Society for Prevention of Cruelty to Children last week, General E. O'Duffy, Chief of Police of the Irish Free State, stated that in 1929 13 infants were murdered, there were 49 cases of concealment of birth, and 10 cases of young children being abandoned; in 1930 12 were murdered, there were 46 cases of concealment, and 11 children were found abandoned; in 1931 7 were murdered, there were 59 cases of concealment, and 8 were found abandoned. Dealing with baby-farming he urged a more effective administration of the present law, and also legislative provisions for the more efficient supervision and control of those who took charge of children. His suggestions included registration and inspection of the premises of any one who proposed to undertake the care and maintenance of children for reward. The registration should be annual, and there should be not only periodic but surprise visits of inspection.

OVERSTRAND HALL AS SANATORIUM.—The Leicester and County Hospital Society has decided to purchase Overstrand Hall, Cromer, for £7000 for a convalescent home. The house, which is said to have cost £67,000 to build some 30 years ago, was one of the early works of Sir Edwin Lutyens, and formerly belonged to Lord Hillingdon. As it stands it will hold 50 beds.

record by the refusal to answer a lawful question, the judge may forthwith order the offender to be apprehended and imprisoned at the judge's discretion without further proof or examination. The High Court of Justice, the Court of Appeal, and the Court of Criminal Appeal are well-known examples of courts of record. The county court judges' power of committal for contempt is specifically dealt with in Sections 162 and 163 of the County Courts Act of 1888. Several generations ago the law officers advised that justices of the peace had no power to commit for contempt, and that the proper course was to indict the offender. Then came Section 7 of the Summary Jurisdiction Act of 1848, whereby a witness, appearing in court in obedience to a summons or warrant, may be committed to gaol for a period not exceeding seven days if he refuses to answer such questions as are put to him "without offering any just excuse for such refusal." If a witness appears voluntarily and is not brought before the court by summons or warrant, there is no such power to commit him. Whether the priest's explanation of his reasons amounted to "just excuse for such refusal" is not clear. The magistrates seem to have suggested that it did not, but, as already stated, the point was not pressed.

The position of priest and medical practitioner is in this respect comparable. The law may find means to put pressure upon each of them to answer some lawful question. There is no doubt whatever of the legal authority to exert this pressure. Judges and magistrates are sensible men, and will not be unaware of the substantial grounds on which a doctor claims (in the interests of his patient, of course, not in his own interests) the medical privilege which instructed public opinion approves. Thus a respectfully worded protest and explanation of the witness's difficulty will often win the court (as at Nottingham) to a tolerant recognition of the witness's genuine scruples and may avoid a crisis. If the court insists upon an answer, the witness may find himself in the position (which the witness at Nottingham would doubtless have adopted) of submitting to imprisonment with firmness in defence of the principle that confidence must not be violated. The less that such martyrdom can be accused of sham heroics or self-advertisement, the more impressive will be the effect upon public opinion. Without stirring public opinion the law will not be changed. Meanwhile there must occasionally be a definite clash between the admittedly well-founded principle of medical secrecy and the equally necessary condition of judicial authority. It is desirable that Parliament and Government departments should not multiply the occasions of conflict nor exacerbate them when they occur.

VIENNA

(FROM OUR OWN CORRESPONDENT)

CONGRESS OF GERMAN PÆDIATRICIANS IN VIENNA

A LARGE number of specialists on diseases of children, coming from many European countries and from North and South America, assembled last month in Vienna for the forty-third meeting of the Deutsche Gesellschaft für Kinderheilkunde, Prof. Freund, of Breslau, presiding. The discussions took place under three headings: (1) eugenic problems in pædiatrics; (2) pyuric conditions in children; and (3) the influence of atmosphere and climate on the child. In an introductory address Prof. Hamburger, chief of the Vienna Clinic for Children's Diseases, pointed out the progress made in research in this special branch within the last 40 years. Not only therapy, but especially prophylaxis, marked the advance in knowledge. A number of formerly lethal diseases such as diphtheria, scarlet fever, tetanus, tuberculosis, syphilis, and rickets had become much less frequent and virulent, or were on the verge of being exterminated. The prophylactic measures adopted by public health authorities, he said, had brought down infant mortality to low figures compared with the appalling percentage half a century ago. Welfare care for infants was chiefly responsible for the drop in the infant mortality-rates of many nations. Rickets, which 20 years ago was a disease of everyday occurrence, was nowadays almost extinct. Tuberculosis of childhood was less frequent and less dangerous; syphilis in children had become rare; nervous diseases in childhood however had increased in frequency, though it was also kept under better control.

The first communication (on eugenics) was presented by Prof. Pfaundler (Munich) who dealt with heredity, chiefly in connexion with twins, and laid special stress on the fact that besides the influence of the surroundings (the "milieu") a prominent part is played by hereditary strain ("erbliche Belastung"). These factors have hitherto been rather neglected in the study of pædiatrics. It is known that certain morbid conditions can be influenced by therapeutic measures, but they can be handed down from ancestor to progeny. Prof. Pfaundler's thesis was that advances in therapeutics may help the individual, but they endanger often the stock of health in the population. The physician is often faced by a dilemma. As a healer he should save life not worth living; as a eugenic statesman he should prevent a future danger to the community. For instance, juvenile diabetics can nowadays be kept alive by insulin, but they may live only to transmit their faulty or deficient metabolism to their descendants. Therefore the eugenic physician must study the disturbances caused by endocrine deficiencies or metabolic faults; and the pædiatrician must also be a matrimonial adviser. In the ensuing discussion the researches by Prof. Hammerschlag (Vienna) on hereditary deafness and deaf-muteness were praised, and the transmission of colour-blindness and hæmophilia were discussed.

The opening paper on pyuria was presented jointly by Nöggerath (Freiburg) and Lichtenberg (Berlin). They elucidated the problem from the standpoint of the pathologist and the clinician, and showed that the frequency of this condition is often underrated. Diagnosis should be easy if the possibility of pyuria is kept in mind in obscure cases of pyrexia. A lively discussion followed this communication, which was followed by papers on urographic methods on the child, by Frick (Giessen); chronic nephritis in childhood, by Geldrich (Budapest); and galactosuria in the child, by Fanconi (Zurich). A number of physicians presented papers on infectious diseases in infants, on the value of prophylactic vaccination and serum treatment in scarlet fever and in pertussis, and on myocardial complications in influenza and pneumonia. These papers came mostly from Hungarian and some Rumanian physicians. The third discussion, dealing with the effect of climate and weather upon the health of children, was opened by de Rudder (Munich) and Moll (Vienna). The first-named has studied the effects of climatic conditions upon start and development of disease. After explaining the effects of cyclone and anticyclone, high and low barometric pressure, and showing the paper again. However, when a doctor gives a certificate which contains an untrue statement he can be brought before the General Medical Council; there is no similar tribunal to deal with the clergyman, the bank manager, and the other select few nominated by authority as competent to do this work.

The seventh visit was to the elderly maiden lady whose finances I supervise. She has swollen feet and has recently been moved from the home of her ancestors to a furnished bed-sitting room, where I hope she will be able to pay her way and not get further into debt. I report the size of her overdraft, that her house has not been let by her agents, and that I have had to persuade one of the people to whom she is indebted not to issue a summons. All these things she takes cheerfully. In return she tells me how necessary it is for a cat to take liver only half cooked, and assures me she will be the possessor of much wealth very shortly. There is not much medical treatment in this case, nor much hope of affluence in the future. The next visit was to an elderly lady whose heart is frequently troublesome, and who had been stung by a wasp; the sting looked angry. Then to a young servant girl who has acute rheumatism, temp. 102° F., swollen wrists, and painful left knee. She was going on well.

The tenth visit was to an elderly maiden lady who has early glaucoma in the left eye, with attacks of pain, defective vision in that eye, a high blood pressure, and general feebleness. She was better, and I was not able to make out any increased tension in the left orbit by palpation. She finds time hang heavy as she is unable to get about quickly enough to keep warm. The eleventh and last visit before lunch was to a young school-teacher who suddenly developed German measles. The mother rather hopes that the father will be sent home from his work owing to the infection, but this does not happen. The girl is really very well in spite of a heavy rash.

AFTERNOON

A light and quick lunch was taken at 1.45, and soon after 2 P.M. more patients came for consultation. The first was a heart case, also suffering with pruritus. These cases are difficult to cure. The second was a lady at the climacteric with early myxœdema, who was taking thyroid. Her improvement was noticeable, and she was very grateful. The third case was a woman whom I had sent into hospital for an ectopic gestation some weeks earlier. She had had one miscarriage before, and she wanted to know whether it would be safe for her to have a child. Would she have another ectopic? Not an easy matter to advise upon. The last consultation of the afternoon was with a young wife who suffers from slight alopecia of the scalp and nervous depression. She was worried about her husband; she had found him out telling her lies about his movements, and there were two used theatre tickets in his coat pocket. Money was short, and she did not know what to do about it. Would she go bald, and so never be attractive to her husband again? She was given some lotion for the hair, medicine for her nerves, and some advice on men and women designed to allay suspicions.

As I was about to change for tennis I received a message from my partner asking me to see a rash he was doubtful about. The small boy seemed very ill; was it an infective condition? So I took the car out again, and on the way back I wrote out prescriptions at the chemist's shop for patients requiring medicine to be made up and delivered as soon as possible. After tea I changed and went to the club, but in the middle of the second set I was called to the 'phone about the boy I had seen in the morning with fever and diarrhœa. His temperature was 104° F.; would I come along. So I had to return home, change back into ordinary clothes, and go to see what was the matter. The boy was really the patient of my partner who had been away for the week-end and was taking surgery on this night. On my return from this visit I discussed the whole case with him, and told him what I had done and asked him to carry on. Soon after 7 P.M. I dined, and feeling somewhat tired after my day's work I read a book until bedtime.

Other Days

Is this a normal day's work? Doctors vary in their statements as to the number of patients seen in a day; one man will say he has paid 120 visits, another that he has seen 50 people to-day. The first statement means that he has called at 120 houses, and has been told at most of them that the patient was going on all right. At such houses he made no examination; through experience of the appearance of an ill person he decided the statement was true, and he went on to the next case. Some practitioners are very clever at this sort of thing: eventually they make some ghastly mistake which may ruin their whole life. The other man probably means that he has seen 10 people in the surgery in the morning, 15 people in the evening, and visited 25 persons at their homes. This amount of work is quite consistent with efficient attendance, but allows no time for discussing the vicar or the young person who is always out late at night, to say nothing of politics. It is my opinion quite definitely that the practitioner who takes proper care of the cases he visits and makes sufficient examinations of those that require it, will have to be quite a fast worker to be able to do 30 visits between 9 A.M. and 6.30 P.M. Locality of course makes a difference.

If you are on the surgical or medical staff of a local hospital you may be called to an emergency or have to attend patients in the hospital. This work is done gratuitously. You may receive year by year only a formal vote of thanks from the governing body controlling the hospital, but you will gain experience in the treatment of difficult cases. Another duty you may have to work into your day is to take a patient to see a consultant, which takes time but is worth it. Misunderstandings are avoided and details of new treatments appreciated. And remember the consultant is a person who knows more and more about less and less, and is often glad of the practitioner's general knowledge. Part of the day will be filled up in attending meetings where your presence will be welcome if you show that you are keen to help your fellow practitioners. Schemes of public medical service for contract attendance on the dependents of insured persons are springing up all over the country; these schemes need local committees to run them. The panel committee of your area will want representatives. Travellers will want to interview you about the latest appliances, drugs, and instruments; I should like to pay tribute to the tactful way in which these men impart valuable knowledge to practitioners who will listen to them. Nurses are frequent visitors to the surgery endeavouring to obtain work for which they may have special training. In the early days of practice there will be frequent interviews with life insurance representatives, all eager to ensure your life and probably to make you an examiner of their company for your area.

This does not pretend to be a full list of the duties that fill up the general practitioner's day. He does not make a large income but his life is very interesting.

Articles in this series will include among others:—

County Health Officer.
The Policeman's Doctor.
An Indian Day.
Practice in a Country Town.
The Medico-Legal Expert.
Giving Anæsthetics.
The Coroner.

THE Export Brand of COW AND GATE MILK FOOD has been awarded the Grand Prix at the Salon d'Alimentation, Brussels, the important Food Exhibition in Belgium.

THE DOCTOR'S DAY

"Come, tell me how you live," I cried,
"And what it is you do!"

I.—GENERAL PRACTICE IN A CITY

THE layman's idea of the sort of life the practitioner leads is revealed in phrases such as: "I should not like my nights to be disturbed.' . . . "It must be terrible to be called away to some case just as you are going out for the evening." . . . "Fancy never to be able to make a definite engagement." Yet in actual practice, I think, unless there is an epidemic or a bad patch of emergency calls, this inability to keep a private engagement does not occur weekly, or even monthly. No doctor is bound to go to a street accident or to attend a person who sends for him. He has a perfect right to say "No, call in some other doctor," although he may hesitate to act in this way. While, however, he has a free hand with his private cases he has no such right if he is under agreement to attend an insured person. He must then under penalty respond to any message, and if through professional engagement, absence from home, or other sufficient reason he cannot himself attend, it is his duty to provide a deputy. For this sort of work he is very definitely on duty (self or deputy) for 24 hours in the day.

The following is an account of one recent day's work. I am a member of a firm in a London suburb, and this day probably represents a little above the average amount that I would normally do at this season of the year. It will be seen to include duties which might not be regarded as professional work, but which have to be undertaken for elderly people alone in the world by someone familiar with their wants, their means, and their aspirations.

A Particular Day

On this particular day the night-bell rang at 6 A.M. and a man's voice in the speaking-tube said would the doctor come at once to Mrs. X at the address given; a maternity case, nurse had sent him to ask me to come. The address was not far away, but the name was not known to me as a patient or as a confinement that I was expecting to attend; so after dressing I went to the surgery and looked up this patient's card, and found that my partner had made arrangements for the attendance whilst I was away on holiday. Her measurements were put down and were normal, so collecting the midwifery bag, and having made certain that the stocks it contains of pituitary extract, chloroform, sutures, antiseptics, &c., were in order, I set out and arrived at the case in about 20 minutes from the time I was called. Pains were normal, but progress was slow, and as she began to get tired I decided at about 7.30 to give a little help. I got back at 8.30 to breakfast, after which a shave and a bath made one feel presentable for the morning's work.

NINE O'CLOCK SURGERY

Six patients arrived for attendance. The first was a girl with a nasal catarrh; she did not look well, and the question of early tubercle was considered. The apices of her lungs, back and front, were listened to without discovering any abnormal sounds, and she was given a good tonic and told to return if not better. The telling of a patient when to return to see you again is quite an important duty. It is easy to do with panel patients because it costs them nothing, but I have always felt it a little difficult with private patients because of course it costs them a consultation fee each time they come; patients, however, expect you to tell them this, and I have on more than one occasion been surprised to hear a patient who was obviously ill say that he did not come back as he had not been told to. On the other hand, patients do appreciate the honesty of being told they need not return unless something else crops up to need attention.

The next patient was a man complaining of pain in the back and a cold. He had been working hard in a close atmosphere and getting very hot. Nothing organic to account for his pain was found, and he went away with some medicine apparently satisfied. Then followed a patient, who comes weekly for her panel certificate, suffering from nerve exhaustion. She has had both her ovaries and uterus removed years ago, and in spite of treatment of all sorts, including organotherapy, is still quite unfit for work. She is a loyal patient with implicit confidence in her doctor, but she is rather hysterical, easily annoyed, and extremely sensitive about being thought fit to work. She was sent to the regional medical officer some time ago, and the worry of that visit is still present in her mind. She resents the suggestion that she is thought by her sick visitor to be fit to work, when she has produced a certificate to the society from me saying she is unfit. This patient does not now take medicine unless she is worried by domestic affairs. She has had much trouble with her landladies and consequently many changes of address.

After this came a request from a widow for me to sign a certificate for pension purposes. As the pensioner's signature has to be recorded in my presence, I told the messenger I must make a visit for this purpose as the woman is not well enough to come to me. The last patient had been stung on the leg by a wasp; she had read in the paper how dangerous these stings could be, and would she be all right? She was reassured, treated, and left happily.

THE MORNING ROUND

Writing work followed, and at about 11 A.M. I started my round. The first visit was to an old lady with thrombosed varicose veins in her leg; she suffers from gout, and is inclined to make the most of her trouble. She was definitely better but still complained of pain; she was taking iodide and wanted more medicine. The second visit was to a small boy ill in bed with fever and diarrhœa. I had seen him two days previously, and in spite of careful examination could find nothing to account for his temperature. Paratyphoid, food-poisoning, tubercle were thought of, but nothing definite was again discovered. The case was too early for a Widal reaction to be of value, and I decided to wait and see what happened. The third visit was to the confinement of the early morning. She was going on satisfactorily. The mother had wanted a boy, but was now quite pleased with the girl and had no desire for me to put it back. I visited the chemist who does our dispensing, ordered some medicine to be sent, and then called at the bank to find out the size of my own overdraft as well as that of a patient whose finances I have to supervise.

The fifth visit was to a man with hæmaturia who is on my panel, but not drawing sickness benefit as he is over age. I suspect a papilloma of the bladder, but he refuses to have a special examination at hospital, and is quite comfortable in bed, and the bleeding is settling down. The sixth visit was to the widow who sent up to ask for a pension certificate. This sort of work, as well as the signing of passports, is much on the increase, and they entail an appreciable amount of work and time, when added up for the whole year. The passport does not need to have the signature witnessed but the pension paper does, and makes an extra visit for the day. These people as a rule are poor as well as old, and to get them to sign their name a second time—for they generally bring the paper up already signed—takes time. There is something wrong with the pen, or they cannot find their glasses, or they argue that Dr. X never asked them to sign the and in the recent papers by van Rooyen (ibid., April 15th and Sept. 1st, 1932).

I shall be pleased to supply workers interested in the subject with cultures of the amœba.

I am, Sir, yours faithfully,

ALDO CASTELLANI.

The Ross Institute, Putney Heath, S.W., Nov. 2nd, 1932.

AN ANOMALY OF THE COLON

To the Editor of THE LANCET

SIR,—In your issue of Oct. 29th (p. 940) Prof. Elliot Smith refers to a case exhibiting an anomalous pelvic colon which was found occupying the right side of the abdomen. As the condition appears to be of great rarity it may be of interest to record that only a few days before reading his communication I opened an abdomen by a grid-iron incision for appendicitis, and found the whole of the right iliac fossa occupied by a large loop of pelvic colon. The mesenteric attachment of the loop was well over to the right side of the middle line, whence it descended into the pelvis to join the rectum. I was at first tempted to believe that I had to deal with a transposition of the viscera. Further exploration, however, revealed the true state of affairs, the cæcum and offending appendix being found in the extreme right of the abdomen, separated by coils of small intestine from the abnormally situated pelvic colon.

I am, Sir, yours faithfully,

FRANK FORTY, F.R.C.S.,
Surgical Registrar, General Hospital, Birmingham.

Nov. 2nd, 1932.

AUXILIARY TREATMENT OF TOXIC DIPHTHERIA

To the Editor of THE LANCET

SIR,—Dr. Woodcock, in her article on the auxiliary treatment of toxic diphtheria with glucose and insulin (THE LANCET, Oct. 22nd, p. 894), when speaking of blood-sugar estimations, writes: "Anything in the nature of a routine tolerance test was considered to be out of the question."

We desire to draw attention to the importance of controlling this treatment by repeated blood-sugar estimations. The adequate insulin dosage is often high, and such tests are obviously essential for the avoidance of hypoglycæmia and its attendant deterioration of the myocardium. We agree with Dr. Woodcock that repeated venepuncture is impossible, and it was for this reason that the method of Crecelius and Seifert was adopted by us. At no time did we fail to obtain 0·2 c.cm. of capillary blood from the lobe of the ear.

We believe that the degree of disorder of carbohydrate metabolism is directly dependent on the severity of toxæmia and, therefore, a blood-sugar curve performed as soon as a patient comes under treatment is of considerable assistance in the treatment and prognosis of the case. Further periodical consideration of the glucose-tolerance curve offers valuable information as to the progress of the patient.

We are, Sir, yours faithfully,

E. C. BENN,
F. HUGHES,
STANLEY ALSTEAD.

City Hospital, Little Bromwich, Birmingham,
Nov. 1st, 1932.

To the Editor of THE LANCET

SIR,—I am glad to see from Dr. Woodcock's communication that the value of intravenous glucose treatment in diphtheria is being gradually appreciated. In her publication she combined it with insulin administration. From the work done in this hospital during the past three years we have come to the conclusion that the administration of insulin is not a necessary part of the treatment in all cases. Half of our bad cases have had no insulin and have done very well without. The essential part of the treatment is to procure a hyperglycæmia of some duration. Unless enough glucose is given to produce this, no effect is produced. No amount of glucose given by mouth or subcutaneously will effect any striking benefit, as it never reaches a high enough concentration in the blood. Our work has been based on the hypothesis that diphtheria toxin acts by reducing the negative potential of the colloid particles of the blood, thus tending to produce colloid flocculation. Glucose, being a reducing agent, might overcome this effect in high concentration. To prolong this effect we administer tincture of iodine, alkalis, and thyroid by mouth[1]; if glycosuria persists for more than six hours we then give insulin to stop it. This line of treatment was suggested by McDonagh's work.

Compared with the later results from Birmingham (with glucose and insulin only) our methods have given a greater reduction in the death-rate and a lower incidence of paralysis amongst the survivors. Since 1921 the type of diphtheria present in Bristol has been severe, so that the results given below for the last five years are comparable.

	Total cases.	Deaths.	Case-mortality (per cent.).
Orthodox treatment, 1928–29	1235	67	5·4
New treatment, 1930–32	2312	68	2·9

The second series of figures are the malignant "dangerously ill" cases extracted from each group. The intravenous treatment has been applied to this second group of cases only; the condition of the remainder of the 2312 did not warrant this treatment.

	Dangerously ill cases.	Percentage of total admissions.	Deaths.	Case-mortality (per cent.).
Orthodox treatment, 1928–29	243	19	67	27·5
New treatment, 1930–32	463	20	68	14·7

It will be seen that over a large series of cases, whether based on the total completed cases or the malignant cases, the death-rate was nearly halved. In our experience, if 90–120 c.cm. of 20 per cent. glucose and colloidal iodine is given on admission with intravenous antitoxin, with or without insulin, and followed by our other accessories, a second injection is rarely necessary. Over much interference with these desperately ill patients is to be deprecated. Too much glucose can be definitely harmful.

I am, Sir, yours faithfully,

B. A. PETERS, M.D.,
Medical Superintendent, Ham Green Hospital, Bristol.

Nov. 2nd, 1932.

THROMBO-PHLEBITIS MIGRANS AND THROMBO-ANGIITIS OBLITERANS

To the Editor of THE LANCET

SIR,—The two interesting papers, by Dr. Walker and Dr. Kletz respectively, on Thrombo-phlebitis Migrans in your issue of Oct. 29th (pp. 936, 938) give the impression that this type of case was first described and named by Moorhead and Abrahamson in 1928, but in the *Mitt. a. d. Grenzgeb d. Med. u. Chir.* for 1909 (xix., 727) the subject of Springende

CORRESPONDENCE

"A COURSE IN OSTEOPATHY"

To the Editor of The Lancet

Sir,—I have just read your summary (Nov. 5th, p. 1016) of a lecture lately delivered to old students of University College Hospital by Mr. Clifford White on chronic pelvic pain. In the course of his remarks Mr. Clifford White is reported to have said, "The treatment of sacro-iliac strain, in my opinion, should be by manipulation at the hands of a qualified man who has taken a course in osteopathy." It would be interesting to know where the students of University College Hospital are advised to go for "a course in osteopathy," and whether Mr. Clifford White has any first-hand knowledge of this particular form of American activity. It may not be irrelevant to remark that University College is the only teaching hospital in London that has not got an orthopædic surgeon on its staff.

I am, Sir, yours faithfully,
A. S. Blundell Bankart.
London, W., Nov. 4th, 1932.

CARBOHYDRATE METABOLISM IN TOXIC GOITRE

To the Editor of The Lancet

Sir,—Under this heading you comment (Oct. 22nd, p. 908) on some recent work by H. J. John on the relationship between hyperthyroidism and diabetes mellitus as it appears clinically. Experimentally, a good deal of evidence exists which throws light on this relationship, and since no reference is made to this either in your comment or in Dr. John's article, I venture to summarise briefly this evidence. I have dealt with it at greater length in my book "Fever, Heat Regulation and the Thyroid Adrenal Apparatus," where also the application of the experimental findings to clinical conditions, including the glycosuria of hyperthyroidism, is discussed.

The experimental investigation has shown that hyperthyroidism and diabetes mellitus have many fundamental features in common. There is in both hyperactivity of the glycogenic function of the liver, meaning thereby an increased formation of carbohydrate from protein and a more rapid pouring out of sugar into the blood. This accounts for the similarity of the nitrogen metabolism in both conditions, and also for the fact that the liver is rendered glycogen-free both in experimental hyperthyroidism and in experimental diabetes. The absence of glycogen in the liver in these two conditions should not be interpreted as being due to an inability to "store" glycogen. One difference between the two conditions is that in diabetes mellitus the increased pouring out of sugar into the blood stream occurs in an organism in which the power of the tissues to oxidise sugar is impaired, so *that the blood-sugar rises and* sugar appears in the urine, while in hyperthyroidism there is general sympathetic stimulation with increased cellular activity, so *that the increased output of sugar* into the blood is dealt with by increased oxidation. The blood-sugar does not rise, therefore, and no sugar appears in the urine, but it is clear that glycosuria can appear more easily in such a condition than in a normal organism.

The essential dissimilarity between the two conditions lies in their intrinsic ætiology. The glycogenic function of the liver is influenced on the one side by the internal secretions of the thyroid and adrenal glands which stimulate it, and on the other side by the secretion of the islands of Langerhans which inhibits it. Hyperthyroidism—and hyperadrenalism—produce an increase in the glycogenic function of the liver as part of the general sympathetic stimulation, whereas in diabetes mellitus the operative removal or insufficient functioning of the Langerhans islets produces an increased glycogenic function by removal of an inhibition.

This conception is based essentially on the view of the glycogenic function of the liver as an autonomous internal secretion, and not as is generally done as a means of providing a "store" of carbohydrate in the liver. I have discussed the difference implied by these two conceptions at some length in my book, and it would take too much space to discuss it here. But as an example I may quote here the view expressed by Dr. John in the summary of his article, that of the factors which influence the "glycogenic depletion" of the liver one is: "a high metabolic rate which causes increased consumption of carbohydrate and depletes the insulinogenic stores, with resultant depletion of the glycogen store in the liver." This is tantamount to stating that when the speed of a motor-car is increased and more petrol is consumed, the increased speed—i.e., the high metabolic rate—causes the increased consumption of petrol, whereas, of course, exactly the reverse represents the causal connexion.

The conception outlined above enables us to understand why in hyperthyroidism glycosuria may appear more readily than in a normal organism, why insulin has a beneficial effect in hyperthyroidism, why the reverse combination—thyroid administration in diabetes mellitus—has a harmful effect, why the fever produced by certain bacterial infections aggravates the hyperglycæmia and glycosuria in diabetes mellitus, and a number of other clinical observations.—I am, Sir, yours faithfully,
W. Cramer.
Imperial Cancer Research Fund, Nov. 3rd, 1932.

PROTEOLYTIC FERMENT IN AMŒBIC DYSENTERY

To the Editor of The Lancet

Sir,—In your issue of Oct. 29th (p. 972) Dr. H. M. Woodcock states that there are many reasons for doubting that amœbæ may secrete a proteolytic ferment. It is interesting to note, however, that there is an amœba (*Hartmanella castellanii*, Mackenzie Douglas) which secretes a proteolytic enzyme with certainty, as, when grown on gelatin and serum, it will produce liquefaction of these media. Moreover, if an emulsion of the amœba is filtered through a Berkefeld candle and a few drops of the filtrate are placed on a gelatin slope, pitting of the medium will be produced within 24 to 48 hours. To grow the amœba on gelatin or serum, the presence of certain bacteria or fungi (alive or dead) is necessary, but I have used in my experiments a bacterium and a fungus which do not produce liquefaction: *Bacillus typhosus* and *Cryptococcus pararoseus*. Of course these experiments do not mean that the ferment will have a lytic action on living cells and tissues; they simply mean that a proteolytic ferment may be produced by an amœba. Further particulars of this amœba may be found in my paper in the *Journal of Tropical Medicine and Hygiene*, July 1st, 1930, in a paper by Mackenzie Douglas (ibid., Sept. 1st, 1930), Prigosen undertook an investigation on similar lines with mice and failed to get any evidence of it. Dr. Cramer is adopting a novel method of scientific criticism in stating that the negative results of Wood and Prigosen mean that we cannot maintain the positive nature of our own results. Not a single criticism has been made against the technique by which we obtained these results, while negative findings may easily be due to lack of observance of the many points in technique which are essential if a positive result is to be obtained. We have, on several occasions, drawn attention to the fact that the response of animals to tumour inoculations depends on the nature of the material inoculated. An animal may become effectively protected against tumour growth or it may show the opposite effect, so that the tumour grows in it at a more rapid rate than in the normal animal. It is easy to point to factors which may bring about negative results, but it is surely unwarranted to set aside the positive so lightly. To illustrate the influence which the condition of the tumour has on its power to confer immunity we have made a table of data which have already been published in various journals, showing the extraordinary range of effect produced by inoculations of tumour cells depending on their treatment and condition at the time of inoculation. In three of these experiments rats have been given an inoculation of tumour tissue, afterwards they have been given a test inoculation at the same time as controls in order to find out what degree of immunity has been produced by the first inoculation.

TABLE

	Units.
Volume of control tumours taken as	100
Volume of tumours in rats treated with irradiated rapidly growing tumours (lethal dose of radiation) ..	7
Volume of tumours in rats treated with irradiated tumours which had stopped growing but were not obviously necrotic (lethal dose of radiation)	52
In rats bearing two tumours, one being given a lethal dose of irradiation, volume of non-irradiated tumours compared with controls in untreated rats	35
Volume of tumours in rats treated with extract of autolysed tumour..	266

The dose of irradiation given to the tumour is of the greatest importance, as if it is not enough the tumour will grow, and if irradiated too long the tumour tissue loses its immunising properties.

Dr. Cramer states (p. 97) that:

> "tumour strains which show spontaneous regression frequently, such as mouse carcinoma 206 or Jensen's rat sarcoma (J.R.S.), are utterly unsuited for radiotherapeutic experiments, and indeed for all therapeutic experiments.'

This is followed a little later on by an illustrative experiment which runs as follows:

> "A rat is inoculated with a piece of J.R.S. The tumour grows progressively; ten days after the first inoculation a second inoculation is performed on the opposite side. This second inoculation is then negative, that is to say the animal has become 'immune.'"

Dr. Cramer's views of Jensen's rat sarcoma are those of many years ago, and do not take into account the progress which has been made in the technique of propagation of this tumour. In the early days inoculations were made with no particular care to ensure the most healthy condition of the tissue, and without knowledge of the many factors which influence results. The J.R.S. as we have it growing at the present time has many of the characteristics of a spontaneous tumour. Spontaneous absorption very rarely takes place, practically all the tumours grow progressively, metastases are common if the rat is allowed to live long enough, and successful treatment seems to depend upon the same factors as the treatment of cancer in man. We have found that when the tumours grow progressively the rats are not as a rule immune to a subsequent inoculation, in contrast to Dr. Cramer's statement; perhaps our criterion for "progressive" growth is different from that of Dr. Cramer.

It is curious to find that Dr. Cramer thinks this tumour of no value for therapeutic investigation, in view of the fact that the technique adopted for the treatment of uterine cancer at the Marie Curie Hospital has made use of the experimental investigations on the lethal action of radium on this tumour. This clinic has systematically published its results, and how far its attempts to modify the technique, on the lines suggested by laboratory investigations, have been justified may be seen by reference to the last radium report of the Medical Research Council.[3]

The greater part of Dr. Cramer's article is concerned with the effects of radium irradiation upon tumour behaviour. He does not seem to recognise that the results of irradiating living structures depend almost entirely upon the dosage employed, the term "dosage" including not only the quantity of energy liberated and the way in which it is liberated, but also the type of radiation used. It sounds almost commonplace to say that all living tissues can be damaged by radiation to the extent of complete necrosis if enough radiation is applied. The whole subject is bound up with the question of dosage, and Dr. Cramer gives very few details of this very important side of his investigation, and yet he does not refrain from ex-cathedra statements on the subject. On p. 97 he says, with reference to his own experiments on the irradiation of a tumour, "these experiments represent the most favourable conditions for the demonstration of any general therapeutic action of radium, if such an *action* existed." In order to find the most favourable conditions it would certainly be necessary to work over a very large range of radiological variations, but we find no evidence that he has done this, and in fact he cites an experiment with a radium capsule which he considers to be on the most favourable lines, which we should feel inclined to condemn on many technical counts. Dr. Cramer attempts to irradiate a tumour in the mouse by applying to its surface a radium capsule containing about 58 mg. of radium and screened by 0·18 mm. of silver. Most of the effects would be due to the beta rays and these are rapidly absorbed in going from layer to layer, so that there would be very big variations in the dose given to the tumour cells in the various parts of the tumour.

Finally Dr. Cramer gives the details of certain experiments contrasting the effects of in-vitro and in-vivo doses on tumours. These can quite easily be reconciled with the experimental fact that was shown in a publication in the *British Journal of Radiology* five years ago,[4] that the growth of a tumour is profoundly influenced by irradiation of the tissues in which it is growing, even when the tumour itself is not irradiated.

The evidence seems to us conclusive that in the case of transplanted tumours in rats the absorption of tumour tissue can lead to the development of an acquired immunity, and this can affect an established tumour and it persists throughout the animal's life. Radiation is one method of causing the absorption of tumour tissue.

The fact that most cases of untreated cancer in man die of the disease and only show a temporary and varying resistance to the progress of the growth,

[4] The Growth of Tumour in Tissues Exposed to X Rays and Radium, Brit. Jour. Rad. (B.I.R. Sect.), 1927, xxxii., 289.

Thrombosen—that is to say, attacks of thrombosis springing or *migrating* from one place to another—was dealt with by Karl Försterling, who gave references to previous literature. In 1907 I consulted the late Sir A. Pearce Gould in regard to a typical sufferer of the kind because he had described a remarkable case in his Lettsomian lectures (*Trans. Med. Soc. Lond.*, 1902, xxv., 165); his patient "out of 25 years had spent no less than six years, two months, and one week invalided by these successive clottings." Pearce Gould, however, did not use the term "migrating" thrombosis or thrombo-phlebitis.

In a recent paper with Dr. E. Schwarz on Thrombophlebitis Migrans vel Recurrens (*Practitioner*, 1928, cxxviii., 421) I referred to a case associated with Buerger's disease (thrombo-angiitis obliterans), which I have observed at intervals since May, 1906.

The patient, a Russian Jew, now aged 66 years, came to England at the age of 25, and the symptoms of thrombo-angiitis obliterans commenced gradually at the age of 38, with intermittent claudication in the left leg. The disease progressed by exacerbations, both lower extremities and the right upper extremity becoming involved and besides the typical symptoms he suffered from attacks of superficial thrombo-phlebitis, notably of the cutaneous nodular type. Since 1924 there have been no active signs of the disease, but the patient has had slight attacks of gout, and has developed permanent high blood pressure.

When I first described this case in *The Lancet* for Jan. 18th, 1908 (p. 152) under the heading *Arteritis* Obliterans of the Lower Extremity (with references to other cases) Buerger had not yet published his first paper on the subject of thrombo-angiitis obliterans; the thrombo-phlebitis portion of the disease showed itself later on in this case. Buerger's first communication was to the New York Pathological Society in March, 1908, and in the *American Journal of Medical Sciences* for October, 1908 (cxxxvi., 567), he published another excellent study of the subject. Its association with "migrating thrombo-phlebitis" was specially considered by him in the *International Clinics* in 1909 (19th series, iii., 85) and in the *Journal of the American Medical Association* in the same year (1909, lii., 1319).

I am, Sir, yours faithfully,

London, W., Nov. 6th, 1932. F. PARKES WEBER.

AMBULATORY TREATMENT OF LEG FRACTURES

To the Editor of THE LANCET

SIR,—In your issue of Nov. 5th (p. 1012) is an annotation describing my apparatus for the reduction of fractures of the shafts of the leg bones, and discussing the after-treatment which I employ. May I be allowed to avoid possible misconceptions by amplifying the statement that these cases are allowed to walk in plaster from the third week? This is only true of transverse fractures, completely reduced, and completely immobilised. In oblique and spiral fractures, weight-bearing is deferred until the sixth week. On the other hand in Pott-Dupuytren fractures weight is borne from the first day. No patient with a fracture of both leg bones is allowed early weight-bearing unless reduction is quite perfect. It is not enough that the alignment be perfect; there must also be accurate end-to-end apposition. If this condition is satisfied, any weight which may be borne through the tibia itself will merely impact the fragments, and if the plaster fits so closely that the fragments cannot angulate, they cannot over-ride.

The advantages of early weight-bearing are undoubted. Consolidation of the fracture is accelerated, muscle atrophy is avoided, adhesion formation is minimised, and the patient is less inconvenienced than by any alternative method of treatment. But unless the surgeon is entirely satisfied that no displacement remains, and that the plaster is so skilfully applied that the fragments cannot move within it, it would be better to avoid the luxury of early weight-bearing. The apparatus was designed primarily to facilitate perfect reduction by a conservative method. It may be that some surgeons are sufficiently expert not to require its assistance, but for the surgeon who finds these fractures difficult to reduce it is invaluable.

I am, Sir, yours faithfully,

Liverpool, Nov. 7th, 1932. R. WATSON JONES.

TYPHOID IN YORKSHIRE

To the Editor of THE LANCET

SIR,—In your issue of Nov. 5th it was stated that a girl, a resident of Denby Dale, returned home after spending a holiday at Scarborough and that on a later date she was found to be suffering from typhoid fever. This came as a surprise to the people in Scarborough as there has been no case of typhoid contracted in this town. It is true that the Scarborough corporation came to the help of their neighbours, the Malton council, and received Malton patients in their sanatorium. Inquiries have been made and it has been found that the girl in question did not take her holidays in Scarborough but was a visitor to a village some miles distant from Scarborough, in an area which is not supplied by the corporation with water.

As the statement in your paper is liable to prejudice the reputation of Scarborough for a supply of wholesome water, I should be obliged if you would give publicity to this letter equal to that of the somewhat misleading (though I am sure not intentionally misleading) statement in your last issue.

I am, Sir, yours faithfully,

JUAN BUTLER,
Mayor.

Town Hall, Scarborough, Nov. 7th, 1932.

REACTIONS FOLLOWING TUMOUR IRRADIATION

To the Editor of THE LANCET

SIR,—The object of the following remarks is to draw attention to some statements in Dr. W. Cramer's paper, entitled Experimental Observations on the Therapeutic Action of Radium, in the Tenth Scientific Report of the Imperial Cancer Research Fund.[1] On p. 98 Dr. Cramer says:

> "Several authors (Contamin, 1910; Wedd, Morson, and Russ, 1914) have suggested that a condition of immunity could be induced by inoculating a piece of tumour which had been irradiated 'in vitro' for a period sufficiently long to prevent its growth after inoculation, and that by this procedure it was possible to influence the growth of tumours which were already established. Wood and Prigosen (1915) have shown in a very extensive series of experiments involving several thousands of mice that such a claim could not be substantiated for transplanted tumours."

Dr. Cramer has written to us and explained that this reference (Wedd, Morson, and Russ) really refers to a paper published by us in THE LANCET in 1922.[2] This paper gave the details of experiments showing that not only can a condition of resistance to tumour implantations be set up in a rat by treating it with injections of irradiated tumour, but that an established tumour can be considerably hindered in its growth by similar treatment. Three years later Wood and

MEDICAL NEWS

niversity of Oxford

The Radcliffe prize, which will again be awarded in 1933, of the value of £50, and is awarded by the Master and llows of University College, for research in any branch the medical sciences.

It is open to all graduates of the university who have taken, are taking, a medical degree in the university, and who have ken the degree of bachelor of arts within the last 12 years. ndidates must send in their names to the Secretary of Faculties, niversity Registry, Oxford, on or before Dec. 1st, 1932.

An examination will take place on Saturday, Nov. 26th. 4 P.M. in the department of physiology, for the Francis otch memorial prize. Candidates should send in their ames and qualifications to the board of management, epartment of physiology, Oxford, not later than Saturday, ov. 19th.

The next award of the Rolleston memorial prize, which is ow of the value of about £100, will be in Trinity term 1934.

It is granted for a piece of original research in one of the llowing: animal and vegetable morphology, physiology and athology, and anthropology. Memoirs already published are dmitted to the competition. Candidates should be graduates r research students of Oxford or Cambridge of not more than x years standing, and within ten years of matriculation.

niversity of Cambridge

On Nov. 5th the following degrees were conferred :—

M.D.—M. C. Andrews and J. H. B. Martin.

M.B. and B.Chir.—J. F. Varley.

M.B.—D. B. Cater.

B.Chir.—*J. W. Bromley, J. O. Poynton, and O. S. Tubbs.

* By proxy.

English Conjoint Examining Board

At the Final Examination, held from Oct. 3rd to 26th, the following candidates were approved in the subjects indicated below, but are not yet eligible for diplomas :—

Medicine.—F. C. Abeyesekera, Ceylon and King's Coll.; L G. Anderson, King's Coll.; G. Barasi, St. Bart.'s; R. Bennett, St. Bart.'s; J. G. Bentley, St. Bart.'s; H. W. Burge, King's Coll.; N. Chakravarty, St. Bart.'s; D. D. Coleman, Charing Cross; Patience Craig, Manchester; C. J. Evans, Guy's; R. M. Farrington, Cardiff; H. C. A. Harris, Camb. and St. Thomas's; R. V. Harris, St. Bart.'s; P. G. F. Harvey, St. Bart.'s; A. J. Helfet, Liverpool; G. A. H. Herbert, London; E. C. Herten-Greaven, Camb. and London; J. H. Hudson, Leeds; W. R. S. Hutchinson, Camb. and St. Thomas's; Grace M. Jones, Cardiff; F. B. Khambatta, Bombay; B. H. Kirman, King's Coll.; S. B. Levy, Liverpool; M. B. Lindsay, St. Thomas's; M. J. McCormack, London; K. R. Masani, Univ. Coll.; K. M. A. Perry, Camb. and London; A. G. Potts, Guy's; J. D. Powell, Camb. and St. Bart.'s; W. L. Price, Birmingham; P. B. Rao, Madras and London; Winifred H. Redmond, King's Coll.; A. H. W. Roffey, King's Coll.; B. Samuel, Cardiff; H. S. Shoham, Univ. Coll.; G. S. Steele-Perkins, Camb. and Guy's; S. Sutton, Manchester; T. V. Tattersall, Camb. and Manchester; R. E. S. Turner, Oxford and St. Bart.'s; J. R. Vaid, Punjab and St. Bart.'s; S. P. Wanchoo, Middlesex; G. L. Ward, Camb. and St. George's; A. G. M. Weddell, St. Bart.'s; E. E. S. Wheatley, St. Thomas's; W. H. Whiles, King's Coll.; D. Whittaker, Camb. and St. Thomas's; I. Whittington, St. George's; and C. W. Wollaston, St. Thomas's.

Surgery.—P. H. Addison, St. Mary's; I. B. Asafu-Adjaye, Univ. Coll.; W. O. Baird, L.D.S. Eng., Middlesex; G. E. M. Benson, Oxford and St. Thomas's; M. J. Boering, London; A. R. Boney, St. Bart.'s; D. J. T. Brinkworth, Middlesex; Jean W. D. Calman, Univ. Coll.; H. R. Cara, Liverpool; B. S. Carter, St. Thomas's; A. J. P. Coetzee, L.M.S.S.A. Lond., London; M. M. Cohen, Manchester; D. D. Coleman, Charing Cross; Esther Copperman, Univ. Coll.; A. G. Cross, Camb. and St. Mary's; T. J. Davies, Cardiff and London; H. De, St. George's; C. B. Dharmasena, Ceylon and St. Bart.'s; A. G. Donald, Guy's; J. F. H. Eagles, Bristol; G. J. Evans, Guy's; J. C. G. Evans, St. Thomas's; L. H. Evelyn, Guy's; E. D. Falconer, Guy's; T. Fichardt, Guy's; N. W. Gardener, Guy's; P. H. R. Ghey, Camb. and St. Bart.'s; P. R. Goodfellow, Camb. and Manchester; P. P. Halemani, Bombay and Middlesex; J. L. Hamilton-Paterson, Univ. Coll.; G. L. Hardman, Camb. and St. George's; T. T. Hardy, Oxford and St. Thomas's; B. A. E. Harley, Middlesex; H. R. Hartnell, London; C. A. Hodges, St. Thomas's; W. H. Hughes, St. Mary's; H. V. D. Iles, Guy's; L. G. Irvine, Camb. and London; N. E. Jones, Cardiff; F. R. Kilpatrick, Guy's; A. H. Knowles, Camb. and St. Thomas's; S. B. Lavine, Middlesex; J. A. E. Lawn, St. Bart.'s; F. X. Letellier, Univ. Coll.; R. M. Littledale, Middlesex; A. E. Locke, Guy's; B. McArdle, Guy's; D. P. McCoy, Camb. and St. Bart.'s; J. O. McDonagh, Univ. Coll.; A. B. MacGregor, Camb. and St. Mary's; Rosamund M. L. Mackay, Univ. Coll.; J. P. Mackenzie, Univ. Coll.; J. D. P. Macpherson, St. Thomas's; C. R. Mayou, Birmingham; S. F. Mitchell, Univ. Coll.; M. P. Morel, Camb. and St. Bart.'s; G. R. Morgan, St. Bart.'s; H. J. V. Morton, Camb. and St. Thomas's; J. B. C. Murdoch, Camb. and Guy's; L. R. Norsworthy, St. Bart.'s; R. M. M. C. Orpwood, St. Bart.'s; J. P. O'Shea, Guy's; A. G. Palin, Oxford and St. Thomas's; P. S. Patuck, Univ. Coll.; B. J. Philbin, Manchester; G. Phipps, St. Thomas's; L. E. J. Poulier, Ceylon and St. George's; F. W. Roberts, Middlesex; J. R. Robertson, Oxford and St. Bart.'s; R. D. Roper, Camb. and St. Bart.'s; G. E. Scott, Oxford and St. Thomas's; G. H. Shaw, Camb. and St. Thomas's; B. W. Smith, Guy's; G. H. Stuart, Univ. Coll.; S. Sutton, Manchester; F. W. Thomas, Cardiff; W. E. Thomas, Cardiff; J. L. Treneman, Liverpool; G. L. Ward, Camb. and St. George's; C. J. T. Watson, Camb. and St. George's; J. Wilson, Camb. and St. Bart.'s; C. W. B. Woodham, St. Bart.'s; E. J. S. Woolley, St. George's; R. F. Woolmer, St. Thomas's; Freida Yarmalinsky, Univ. Coll.; and C. H. Yeoh, Oxford and St. Thomas's.

Midwifery.—G. Abbey, Leeds; J. S. Adamson, Bristol; G. G. Airey, St. Mary's; R. M. H. Anning, St. Mary's; J. E. M. Ayoub, Oxford and St. Thomas's; T. A. Baldwin, Univ. Coll.; G. A. Barker, King's Coll.; G. F. Barran, Camb. and St. George's; H. R. Bathurst-Norman, Oxford and St. Thomas's; A. A. W. Beach, L.D.S. Eng., Birmingham; N. B. Betts, Camb. and St. Thomas's; A. Birnbaum, London; M. J. Boering, London; R. Bolton, Univ. Coll.; F. J. Brice, London; R. E. Browne, King's Coll.; E. G. L. Bywaters, Middlesex; W. A. Cannell, L.D.S. Eng., Charing Cross; J. P. Child, Oxford and St. Thomas's; R. D. Clay, King's Coll.; M. M. Cohen, Manchester; J. H. Coles, King's Coll.; R. E. C. Copithorne, Middlesex; Esther Copperman, Univ. Coll.; L. Z. Cosin, Guy's; S. W. Croome, King's Coll.; H. T. Croudace, Guy's; E. M. Darmady, Camb. and St. Bart.'s; Hilda M. S. Davidson, King's Coll.; H. H. Davies, St. Bart.'s; T. J. Davies, Cardiff and London; W. A. Dawes, Camb. and St. Thomas's; C. E. M. De Gruchy, Guy's; W. J. B. De Gruchy, Camb. and St. Thomas's; C. B. Dharmasena, Ceylon and St. Bart.'s; M. E. Disney, London; R. J. Drummond, Guy's; Katharine E. M. Dunne, Camb. and Leeds; O. G. Edholm, St. George's; J. J. A. Embleton, St. Mary's; A. B. Evans, Camb. and Westminster; G. J. Evans, Guy's; S. T. Falla, London; R. G. Bowdler, St. Thomas's; W. D. Bower, Camb. and St. Thomas's; Muriel Boycott, Univ Coll.; F. J. Brice, London; Jean W. D. Calman, Univ. Coll.; W. R. Cambridge, Bristol; R. H. Carpenter, St. Bart.'s; H. F. Chard, St. Thomas's; A. H. Charles, Camb. and St. George's; H. O. Clayton, Manchester; D. M. Cooper, St. Thomas's; R. E. C. Copithorne, Middlesex; J. E. Davenport, Camb. and London; T. J. Davies, Cardiff and London; E. J. Dennison, St. Thomas's; D. P. Dewe, Bristol; P. E. Dipple, St. Bart.'s; M. E. Disney, and the fact that many cases treated by radiation continue to have progressive growth of distant metastases, does not prove that immunity to cancer cannot occur and that no practical value can result from a study of the subject. Actually we have no means of determining whether the numerous cases of advanced cancer cured by radiation, vide 10 years' statistics of such clinics as Radiumhemmet and the Fondation Curie, ever had distant metastases or not. We are not of Dr. Cramer's opinion that the subject of immunity to cancer is solved by negative observations, and we think future progress on this subject is closely linked up with experimental work upon tumours in animals such as the Jensen rat sarcoma, which not only shows at the present time most of the characteristics of a spontaneous new growth but also can be made to produce an effective and lasting immunity in the most sensitive stock.

We are, Sir, yours faithfully,
H. CHAMBERS,
G. M. SCOTT,
S. RUSS.

Barnato Joel Laboratories, Middlesex Hospital, W.,
Nov. 8th, 1932.

THE POLICY OF SCHOOL CLOSURE.—With reference to the letter with this title from Dr. W. Dunn, medical officer to Uppingham School, which appeared in THE LANCET last week, it has been pointed out to us that the official statement of the Ministry of Health on the subject in no way challenged or questioned the competence or authority of headmasters and school medical officers to make decisions as to the closure or non-closure of their own schools. An official account of the Broadstairs epidemic, of which Dr. Dunn required a report, appeared in the annual report of the chief medical officer of the Ministry of Health in 1926.

A STUDENTS' HOSTEL

TWO years ago an appeal was made for money to build a hostel for students of the London Hospital. It is strongly felt by the hospital staff that medical students ought to have the chance of enjoying "something comparable to the life of Oxford and Cambridge colleges," and the London has hitherto been able to offer hostel accommodation to a small number.

Since the first appeal was issued the sum of £10,000 in cash and promises has been raised. Of this, £4000 has been subscribed by members of the staff and other old London Hospital men; £2000 was obtained through an old London Hospital man in general practice, who was consulted about the disposal of a trust fund; £3000 has been voted towards the scheme by the house committee, from the Knutsford memorial fund; and £1000 has just been contributed by Sir Evan Spicer, a member of that committee. For the new building described below a total of £23,000 is required, without allowing for furniture or decorations; but it has been decided to proceed at once with the building of the north wing, which will contain the dining-hall, library, and kitchen, and a number of rooms for staff accommodation.

The site is an admirable one in Philpot-street, a wide street behind the hospital. The hostel itself has been planned on simple and straightforward lines. On the ground floor one enters into a hall with the common-room on one side and the dining-room on the other. Beyond the common-room there is the library in a quiet position for study, and beyond the dining-room is the servery and the kitchen offices. The hall itself gives direct access to a small garden facing east.

The staircases are on the two internal angles of the building, giving access to the 55 bed sitting-rooms for students. Care is being taken that these shall be simple, quiet, comfortable rooms. There is an ample supply of baths and lavatories on each floor. Special accommodation has been made for the warden and also for the matron. The kitchen and staff quarters are shut off by a door from the rest of the building on each floor. The plan has been so arranged that extensions in the future could be made with the least possible disturbance.

Externally the building will be in brick in harmony with its neighbours, but its design is particularly direct and modern in spirit, relying on good proportion, materials, and workmanship rather than ornament. The architect is Mr. Edward Maufe, F.R.I.B.A.

The hon. secretary of the hostel committee is Dr. A. E. Clark-Kennedy.

Hospital, Liverpool, and honorary surgeon to the
for Women.
title of professor emeritus has been conferred upon
S. Macdonald, F.R.S., Holt professor of physiology
914 until this year.

University of London

Dr. A. M. H. Gray, dean of University College medical school, has been elected *dean of the medic* of the university for 1932–34. Mr. William M.D., has been elected dean of the faculty of musi

Sir Charles Sherrington will give the first of two on Reflex Action at University College, Gower-street, on Nov. 17th, at 5.30 P.M. The second lecture w take place on the 24th, as announced in our last issu, has been postponed until next term.

Mr. J. A. Hewitt, D.Sc., will give four lectures o Influence of Ductless Glands on Metabolism, at K College, Strand, W.C., at 5 P.M., on Thursdays from Nov. to Dec. 1st.

University of Bristol

A dissertation by Dr. Ronald Melville Norman has approved for the degree of M.D.

University of Durham

At the College of Medicine, Newcastle-upon-Tyne, Friday, Nov. 25th, at 4.45 P.M., Dr. E. D. Adrian, F.R Foulerton professor of the Royal Society, will deliver third of a series of lectures on Recent Advances in Physiolo Applicable to Medicine. His subject will be the *Senso Control of Respiration and of the Heart Beat. Medic practitioners are invited to attend.*

Fellowship of Medicine and Post-Graduate Medic Association

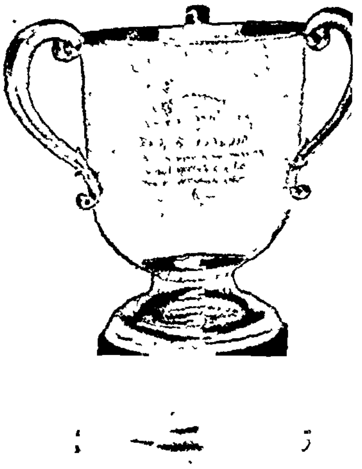
A course of six lecture-demonstrations on the Diagnos and Treatment of Chronic Rheumatism will be held at t *British Red Cross Clinic* for Rheumatism, Peto-plac *London*, N.W., from Nov. 22nd to Dec. 8th. on Tuesda and Thursdays at 8.30 P.M. Mr. R. Lindsay Rea will gi a demonstration on *the Fundus Oculi on Tuesday*, Nov. 22n at 8.30 P.M., at the in-patient department of the West-E Hospital for Nervous Diseases, Gloucester-gate, N. *There will be a course in proctology* at St. Mark's Hospit City-road, E.C., from Nov. 21st to 26th. There a vacancies *for two clinical assistants* each month (men on at the Lambeth Hospital, Brook-street, S.E. Furt details may be had from the secretary of the Fellows at 1, Wimpole-street, W.1.

Princess Elizabeth of York Hospital

With the sanction of the King the East London Hosp *for Children*, Shadwell, London, E., has changed its name *Princess Elizabeth of York Hospital* for Children.

Harveian Society of London

Last June the Harveian Society of London held th 101st annual banquet, which is now known as the Buckst Browne dinner, because of the kindness of Sir Geo Buckston Browne in providing the society with a sum money which enables the members *to dine together*. T president, Mr. Cecil P. G. Wakeley, reminded the memb and guests that *Sir Buckston* Browne had instituted the dinner in memory of his only son, Lieut.-Colonel George Buckston Browne, D.S.O., a very *gallant* officer who was killed in the war. Lord Riddell, who was the principal guest at *the banquet*, proposing the toast of the society in his ever happy manner, said that he was moved by the generosity of Sir Buckston to present the society with a *loving cup to be* used at the annual Buckston Browne dinner. This cup has now been received by the society. *It consists* of a cup of plain George III. form, with flanched rim and three scroll handles, with leaf terminations, 13 in. high, gilt and standing on *a plinth* of art green wood. On one side of the cup is an engraved portrait of Harvey, while on the *other* side the names of the donor, the president, Mr. Wakeley, and the treasurer, Dr. Godfrey de Bec Turtle, are engraved. The cup was made, and the engraving executed by Messrs. J. W. Benson, Ltd., Ludgate-hill, E.C.



]

removal shall not take effect, unless the insured person in the meantime applies to and is accepted by another practitioner, until fourteen days after the date on which the practitioner notifies the committee that the insured person is fit to resume work; but this paragraph shall not apply in any case in which, owing to the chronic nature of the insured person's illness, medical certificates are, under the terms of the medical certification rules, being given at less frequent intervals than one week.

This clause is put in to protect insured persons being unloaded on the service during an acute illness. It will be seen that (subject to no acceptance by another doctor) the delay in removal is conditional on the patient being (1) in receipt of treatment, (2) incapable of work; but a chronic case, as defined in the clause, is an exception to the rule. The certificate in question is the pink form 40 B, containing the phrase "Your incapacity is of such a character that it will be unnecessary to see you for the purpose of treatment more frequently than once in . . . weeks." (The blank period may not be more than four.) This procedure would appear to be fair to all parties in the case of chronic invalids who are receiving such certificates, but there are a number of old and infirm insured persons who by reason of being over 65 do not receive any certificates at all, and from the above it would appear to be impossible for the insurance doctor who may be attending such a really chronic case ever to be able to get that case removed from his list under the clause mentioned above, as if he gets no certificates he cannot be said to be receiving certificates "at less frequent intervals than one week."

Lost Cheques

It occasionally happens that an insurance practitioner does not receive the cheque issued to him quarterly by the insurance committee. It may be lost in the post, lost in the doctor's house, lost in the committee's office. When he applies for the issue of another cheque the usual procedure is for the committee to require him to sign a form which guarantees the committee against loss through the issue of a second cheque. The signing of an indemnity form might be fair if the practitioner admits he has had the cheque and lost it, but not when it is denied that he has never received it. This matter was discussed at the last meeting of the London panel committee when it was decided to ask the Insurance Acts committee to take the matter up with the Ministry.

A Correction

Last week it was stated that the conference of the National Association of Insurance Committees passed a resolution to suggest the alteration of Clause 7 III. from a period of one month to that of three months. This was the original proposition, but an amendment by London was carried, under which the alteration suggested was six weeks and not three months.

PUBLIC HEALTH SERVICES

Typhoid in Yorkshire

LAST week we gave some account of two epidemics of typhoid in Yorkshire—one in the West Riding, near Huddersfield, the other in the North Riding, at and around Malton—and were enabled by the courtesy of the medical officer of health to set out in the former case how the infection arose. Dr. L. C. Walker, medical officer of health (urban and rural) for Malton, has sent us similar details for his own area. "The various medical practitioners in the town," he writes, "realised towards the end of the week ending Oct. 22nd that there were several probable cases of typhoid, but it was not until the 22nd that the first case of typhoid was notified. Another case was notified on the 23rd and 15 cases on the 24th. On Sunday, the 23rd, when it was evident that there was a possibility of a sudden epidemic arising, I began to take the necessary precautions. I arranged for the bellman to go round the town on the Monday morning, warning people that both water and milk should be boiled, and notices to the same effect were distributed to every house in the town twice on that day. I had already taken a sample of water from our town supply on the 23rd for bacteriological examination, and on the Monday my sanitary inspector went into the question whether any connexion could be made out between the milk-supply of the town and the epidemic. As there were so many different milk retailers and no general wholesalers this was at once, and easily, ruled out. The explosive character of the epidemic, however, made us suspect that the cause could be nothing but the water-supply.

"The water-supply of Malton is actually taken from a well on the lower oolite practically at river level, and from this well pumped up to a reservoir on the higher part of the town. Malton is situated on the southern spurs of the Castle Howard Hills, on limestone. This overlies a bed of clay, and the springs come out between the two. Quite near the river and owing to the clay the tendency is for this water to drain down towards our well rather than into the river. During pumping hours the supply goes direct to the houses, and when pumping is not being carried on the supply is carried from the reservoir. As there was no definite source of pollution in the neighbourhood of the well we had to look for a possible source elsewhere. There had been no flooding for some time, so there was no question of pollution from this source. The nearest known possible source of pollution was a case of typhoid at the poor-law institution, a distance of about 200 yards from the well and somewhat above it. This case of typhoid had entered the institution on Sept. 21st, and from about the 24th or 25th had been treated as a typhoid under the head charge nurse.

"We therefore attempted to find some connexion between this case and our well, and thought at first that there might be a possibility of a direct leak into our main, if cracked, from the drains of the workhouse. At one place they were quite near together, but on excavating we found that there was no sign of leakage. We then tested by water the next part of the drain, and found it impossible to fill this length of the drain, which measured only some 20 yards from one inspection chamber to the next; although we had five taps pouring water into the drain for about an hour and a half it was impossible to fill this section; in fact, after removing the plugs it was still almost empty. We continued excavation of the drain and eventually found that at one place, where work had been done about 18 months ago on some electric cables, two holes had been made in the drain by a workman's pick, and the water teemed out of these holes as fast as we put it in. This was the last occasion on which the ground had been opened in the region of this drain. Below the holes were appreciable cavities where the soil had been washed away, and the water from our taps disappeared through these cavities as fast as we put it into the drain. This

PANEL AND CONTRACT PRACTICE

Scope of Treatment under the Act

THE terms of service provide that the medical treatment which an insurance practitioner is required to give to an insured person shall include :—

> "All proper and necessary medical services other than those involving the application of special skill and experience of a degree or kind which general practitioners as a class cannot reasonably be expected to possess."

The insured person is therefore not entitled to a medical service which involves the application of special skill and experience, and the doctor giving such a service is entitled to charge the insured person for such service, providing he can satisfy both the local medical committee and the insurance committee for the area that the service did involve the application of special skill and experience and that he was qualified to give it. It is noteworthy that both special skill and experience are required; it would not be enough to have special skill alone, the practitioner must have experience. The dictionary defines skill as "familiar knowledge of any art united with dexterity in the practice of it," and dexterity as "a ready expertness due to practice in the employment of mechanical or mental resources"; experience is "the ascertained result of a series of trials or experiments." The practitioner who claims to be making a service which is outside the Act must accordingly have familiar knowledge of the service, combined with a ready expertness due to practice in the employment of mechanical or mental resources for this service, and he must know the result of a series of similar trials of it.

MANUAL AND MENTAL DEXTERITY

Anyone who glances through a list of services for which fees have been claimed (on form G.P.45), on the ground they are outside the Act, is likely to be impressed by the number of cases in which fees are allowed where the employment of mechanical rather than mental resources would appear to be the deciding factor in admitting the claim. The enucleation of tonsils, for example, does not require much mental dexterity, but an appreciable amount of manual dexterity. The same would probably hold true for an appendicectomy. Again, another deciding factor for the allowance of fees under G.P.45 might be the provision of expensive apparatus. It would clearly be impossible to demand that every insurance doctor should be possessed of a modern X ray or diathermy plant, or even of an artificial sunlight lamp; a certain amount of manual dexterity is required in using all these pieces of apparatus, but the skill lies largely in the interpretation of results. Claims for fees for such medical services are, as a rule, allowed, because if it were held that the service was within the Act it would follow that any insured person would be able to demand X ray examination as a right from any insurance doctor. On the other hand, no claim for fees has ever been allowed for the service of making a diagnosis, although it may require a special knowledge of a high order combined with a ready expertness in the employment of mechanical and (notably) mental resources. The physician who decides the cause of some localised paralysis and deduces therefrom the appropriate treatment would not have his claims admitted if he filled in G.P.45 for such service. All insurance doctors, being qualified medical men, are however expected to be able to make a diagnosis, no matter how difficult this may be. Hence no special fees are allowed. The physician who diagnoses diabetes would not be allowed fees for the diagnosis nor for the treatment by diet or insulin; but if he estimates the patient's blood-sugar his claim will be allowed because this estimation demands manual and mental dexterity beyond what a practitioner might reasonably be expected to possess. Moreover, in every case where claims under G.P.45 arise it is the practitioner's duty to give the patient the opportunity of getting the special service done for nothing at a hospital.

THE CASE OF PSYCHOTHERAPY

Let us now consider how these arguments apply to psychotherapy, a subject which was discussed again at the last meeting of the London insurance committee. Is psychotherapy a special medical service? First of all, is there any hospital to which a case thought to be needing psychotherapy can be sent, as an out-patient, for treatment? There are certainly not many such hospitals in this country, so that the opportunity to get the service gratuitously will in most cases not be available. Secondly, it is quite certain there is no manual dexterity in this service. There may be some degree of mental dexterity required, but is this of a higher order than that required to make a diagnosis in some forms of nervous disease and for which, as we have seen, no fees would be payable. Does not the treatment given in psychotherapy depend largely on the diagnosis?—for which no doctor is paid by G.P.45. Having arrived at the diagnosis, is the consequent treatment beyond ordinary general practitioner skill? Discussion of the question whether psychotherapy comes under G.P.45 will be resumed at the next meeting of the London insurance committee, and if this committee still decides to differ from the local medical committee, the Ministry will have to place the matter before a court of referees. This would mean expense, but the matter is also expensive to the insured person, who, by the very nature of his trouble, is much under the doctor's influence, and however unable to afford private fees would hardly dare to refuse to pay because of the hope of improvement held out to him by this form of treatment. While the position is one fraught with danger of abuse, it is quite possible for those who are experts in this specialty to give their insured patients such treatment without special fees. It would, of course, be far better if the two committees could agree about the position.

Removal from your List

A rather interesting point arose recently in a medical service case. The regulations provide that an insured person can be removed from an insurance practitioner's list in three ways: by action of the insured person; by action of the insurance committee; or by the insurance practitioner. It was on this last method of procedure that discussion arose. The terms of service provide that a doctor can give notice to his insurance committee at any time to have a person's name removed from his list, but this is subject to certain restrictions as will be seen in the following clause:

> If a practitioner has given notice to the committee of his desire to have an insured person removed from his list and the insured person is, at the date when the removal would take effect, incapable of work, and is receiving treatment from the practitioner, the practitioner shall notify the committee of the insured person's incapacity, and the

something to allay the suspicion that information is being deliberately withheld?

Sir ARTHUR MICHAEL SAMUEL: Is not information obtainable from nickel works in other countries through the International Labour Office?

Sir J. GILMOUR: I do not think that there is anything by which we can directly associate this disease with the processes concerned so far as our present knowledge goes. The examinations which are going to be undertaken may help us to come to some conclusion.

Mr. GRENFELL: Is it not known that cancer is more or less connected with mineral oils such as are used in this process, and is it not important that that should be considered?

Sir J. GILMOUR: All I can say is that those concerned, both in the firm and in my office, are taking every opportunity to study this problem, and the medical officer connected with the firm has gone through a special course quite recently to bring himself up to date with the latest information on this subject.

Relief of Unemployed Persons

Mr. KIRKWOOD asked the Minister of Health whether in view of the poverty that had existed all the summer and the suffering which the approach of winter would cause to the unemployed who had been unable to buy new clothes, bedding, and furniture for years, he would state what arrangements the Government were making to prevent further suffering.—Sir E. HILTON YOUNG replied: The responsibility for providing food, clothing, and shelter for those who are in need, whether on account of unemployment or not, rests with the public assistance authorities. As regards England and Wales, I am watching the situation closely and I am satisfied that the resources of the authorities will be equal to any additional strain which may be placed upon them.

British Meat for Mental Institutions

Sir PERCY HURD asked the Minister of Health whether he was aware that the Cheshire county council had arranged that the meat for the mental institutions under their control should be British and be bought wholesale at the markets and slaughtered by their own officials, the average cost over the 12 months being 4¾*d.* per lb.: and whether he would make this fact known to other local authorities for the encouragement of British agriculture.—Sir E. HILTON YOUNG replied: I am informed that a considerable part of the meat purchased for these institutions is British, and that the average cost for the last 12 months is about 5¼*d.* per lb. I will communicate with my hon. friend with regard to the details and also as to the suggestion contained in the second part of the question.

Slum Clearance and Re-housing

Mr. DENMAN asked the Minister of Health to what extent local authorities in general were carrying out the five-year plans of slum clearance and re-housing submitted to him under the Housing Act, 1930; how many areas were at present in process of being cleared; and how many dwellings were being built for re-housing the persons displaced.

Sir E. HILTON YOUNG replied: I have received resolutions declaring 541 areas in England and Wales, the clearance of which involves the displacement and re-housing of approximately 78.150 persons, to be clearance areas under the Housing Act, 1930. Information as to the number of areas at present in process of being cleared is not available; but 229 clearance or compulsory purchase orders have been confirmed in connexion with such areas. Upwards of 16.000 houses, which are either earmarked or available or the purposes of the Act, have either been erected or are under construction.

Mr. DENMAN: Does the right hon. gentleman think the time has come for speeding up the process of slum clearance and re-housing?

Sir E. HILTON YOUNG: I can assure the hon. Member that there will be no relaxation of effort. At the same time I would point out that, allowing for the necessary difficulties of starting this work, the progress cannot be looked upon as unsatisfactory.

Sir P. HARRIS: Can we be assured that the Ministry of Health are not holding up any of these schemes on the ground of economy?

No further answer was given.

Accidents to Children in London Streets

Mr. RHYS DAVIES asked the Home Secretary the number of street accidents in London during the last 12 months in which children under 5 years of age were involved; and whether it would be possible to obtain similar information with respect to street accidents over the whole country.—Sir J. GILMOUR replied: There were 51 fatalities in street accidents among children under 5 in the metropolitan police district and City of London during the year ended Sept. 30th last. I regret that figures for non-fatal accidents to children under 5, and for fatal or non-fatal accidents to such children for the country as a whole, could not be obtained without incurring considerable expense.

Payment of Income-tax

Mr. HALL-CAINE asked the Chancellor of the Exchequer whether, in view of the improved financial situation, he would consider the advisability of abolishing the existing provision under which 75 per cent. of income-tax payable in respect of the current financial year should be paid on Jan. 1st next and providing for the payment of one-half such amount in lieu thereof, with a view to alleviating as far as possible the burden upon industry and the tendency to create further unemployment that would result from the obligation to pay so large a proportion of the tax at this date.—Mr. CHAMBERLAIN replied: I regret that I could not possibly entertain any suggestion for an alteration of the law governing the collection of the income-tax for the current year. I am afraid that my hon. friend is under a grave misapprehension if he thinks that the present state of the national finances would permit of any relaxation in the collection of the income-tax.

Repairs to a Doctor's Telephone

Mr. PERKINS asked the Postmaster-General whether he was aware that a prominent London doctor working at Westminster Hospital had his telephone (Egham 314) cut off for Oct. 22nd, 23rd, and 24th, and why no attempt was made to repair this telephone until Oct. 25th.—Sir KINGSLEY WOOD replied: I regret to find that by an oversight, of which proper notice will be taken, the circuit Egham 314 was not included in the list of lines scheduled for emergency attention to faults. A considerable number of faults developed in the Egham area during the week-end Oct. 22nd to 24th, owing to abnormal weather conditions, and there was unfortunately some delay in restoring service on circuit Egham 314. The work of repair was, in fact, begun on the 24th. The circuit has now been included in the emergency list.

TUESDAY, NOV. 8TH

Condemned Houses in Edinburgh

Mr. GUY asked the Secretary for Scotland the number of houses in Edinburgh which had been condemned as unfit for habitation and which were still occupied.—Mr. SKELTON replied: The total number of houses in Edinburgh which have been condemned as unfit for human habitation and which are still occupied is 1009.

Safety of Life at Sea

Sir BASIL PETO asked the President of the Board of Trade whether all the five principal maritime powers had ratified the Safety of Life at Sea Convention; and whether, if they had not done so before the end of December, he intended to put the reversal of helm orders in force in the British merchant service on Jan. 1st.—Mr. RUNCIMAN replied: The following countries have ratified and will bring the International Safety of Life at Sea Convention into operation on Jan. 1st, 1933:—United Kingdom, Canada, Denmark, Finland, France, Germany, Italy, Netherlands, Norway, Spain, and Sweden. Steps are being taken to bring the provisions of the Merchant Shipping (Safety and Load Line Convention) Act, 1932, including those relating to Helm Orders, into operation on that date.

Births, Marriages, and Deaths

MARRIAGES

SCOTT TAGGART—BAYSTON.—On Nov. 9th, 1932, at the Parish Church, Cheltenham, Norman, elder son of Dr. and Mrs. J. Scott Taggart, of Peel Moat, Heaton Moor, to Gwendoline, only daughter of Mr. and Mrs. Arthur Bayston, of Cranley Lodge, Cheltenham.

SHAWCROSS—CARTWRIGHT.—On Nov. 2nd, at St. Paul's, Herne Hill, Ellis W. H. Shawcross, M.A., M.R.C.S., of Beckenham, to Gladys L. (Jill), daughter of Mr. and Mrs. Alfred Cartwright, of Herne-hill.

DEATHS

BROWNLOW.—On Nov. 5th, Harry Lurgan Brownlow, F.R.C.S., aged 64.

CROSS.—On Nov. 7th, after a long illness, at Shackleford House, Petersfield, Dr. Robert George Cross, in his 70th year.

HILL.—On Nov. 5th, A. Bostock Hill, M.D., D.P.H., aged 78.

LEDIARD.—On Oct. 31st., at Carlisle, Henry Ambrose Lediard, M.D. Edin., F.R.C.S Eng., J.P., aged 84 years.

POWELL.—On Nov. 1st, suddenly, at Bilton, Herbert Edward Powell, M.R.C.S., L.R.C.P.

WRIGHT.—On Nov. 2nd, at his residence, Hillside, Abinger Common, and late of Eye, Suffolk, Lieut.-Colonel C. F. Wright, J.P., T.D., M.R.C.P., L.S.A., aged 71 years.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

seemed to establish a definite connexion between the cases of typhoid and the well.

"When it was realised on the morning of the 24th that we should probably have a large number of cases, I decided, if possible, to take over the Malton Hospital, a new and up-to-date building, eminently satisfactory for the purposes of an isolation hospital. By sending several cases home and removing those still requiring surgical attention to York County Hospital, it was possible to empty it so that we could take it over as an isolation hospital. By the evening of the 24th we had cleared the hospital and already taken in 8 cases. With 15 cases on the 24th, 10 on the 25th, and the balance made up on the 26th, we had soon filled our total of 38 beds.

"As cases were still crowding in I had to look round for further help, and already having arrangements with York for treating our fever cases, I was enabled to get several beds there. The East Riding county council, through Dr. R. L. Thornley, and later Scarborough isolation hospital, through Dr. S. F. Linton, very kindly came to our rescue and have also taken cases in. At the present moment we are also filling up Leeds. So far we have 168 cases in these various hospitals, and 6 deaths have occurred. There are, in addition, as far as I have been able to find out, about 15 contact cases—people working in Malton or children coming to school in Malton—in various parts of the surrounding country."

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED OCT. 29TH, 1932

Notifications.—The following cases of infectious disease were notified during the week :—Small-pox, 34 (last week 33) ; scarlet fever, 2281 ; diphtheria, 986 ; enteric fever, 138 (last week 83) ; acute pneumonia (primary or influenzal), 838 ; puerperal fever, 31 ; puerperal pyrexia, 109 ; cerebro-spinal fever, 22 ; acute poliomyelitis, 43 ; acute polio-encephalitis, 5 ; encephalitis lethargica, 12 ; continued fever, 1 (Earsdon U.D., Northumberland) ; dysentery, 4 ; ophthalmia neonatorum, 87. No case of cholera, plague, or typhus fever was notified during the week.

Of the cases of small-pox, 27 (i.e., all except 7) were returned from the county of London, distributed thus among the metropolitan boroughs: Bethnal Green and Stepney each 1, Hackney 3, Lambeth 6, Islington 7, Poplar 9.

Of the cases of enteric fever, 80 were reported from the North Riding of Yorkshire (Malton 78, Scarborough 1, Helmsley R.D. 1), and 19 from the West Riding, 8 of which occurred in the urban district of Denby and Cumberworth.

The number of cases in the Infectious Hospitals of the London County Council on Nov. 1st–2nd was as follows:—Small-pox, 64 under treatment, 4 under observation (last week 65 and 4 respectively) ; scarlet fever, 2066 ; diphtheria, 1745 ; enteric fever, 20 ; measles, 222 ; whooping-cough, 348 ; puerperal fever, 21 (plus 8 babies) ; encephalitis lethargica, 231 ; *poliomyelitis, 6 ; "other diseases,"* 162. At St. Margaret's Hospital there were 18 babies (plus 8 Mothers) with ophthalmia neonatorum.

Deaths.—In 117 great towns, including London, there was no death from small-pox or enteric fever, 7 (1) from measles, 10 (1) from scarlet fever, 14 (1) from whooping-cough, 30 (5) from diphtheria, 61 (19) from diarrhœa and enteritis under two years, and 42 (6) from influenza. The figures in parentheses are those for London itself.

Three deaths from diphtheria occurred at Manchester and at Stockport. Birmingham reported 5 fatal cases of influenza, Manchester 3.

The number of stillbirths notified during the week was 266 (corresponding to a rate of 43 per 1000 total births), including 42 in London.

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS

Mental Treatment Act, 1930

IN the House of Commons on Nov. 2nd Sir E. HILTON YOUNG, Minister of Health, moved that the following rules, dated July 28th, 1932, made by the Board of Control with the approval of the Lord Chancellor under Subsection (1) of Section 338 of the Lunacy Act, 1890, as extended by Subsection (2) of Section 21 of the Mental Treatment Act, 1930, which were presented on Oct. 18th, be approved, namely: The Mental Treatment (Lancashire Mental Hospital Board) Rules, 1932. S.R.O., 1932, No. 666 ; the Mental Treatment (Staffordshire Mental Hospitals Board) Rules, 1932. S.R.O., 1932, No. 667 ; The Mental Treatment (West Riding of Yorkshire Mental Hospital Board) Rules 1932. S.R.O., 1932, No. 668.

The motion was agreed to.

Edinburgh Materity Hospital

The Edinburgh Royal Maternity and Simpson Memorial Hospital Order Confirmation Bill (which has already passed through the House of Lords) was read the third time in the House of Commons on Nov.7th.

HOUSE OF COMMONS

WEDNESDAY, NOV. 2ND

The Spahlinger Vaccine

Mr. GROVES asked the Minister of Agriculture whether he had received any reports regarding the testing of the Spahlinger vaccine on cattle in this country ; and whether any conclusions had been reached regarding that vaccine as a preventive of tuberculosis.—Major ELLIOT replied: I have seen the report of the trial of Mr. Spahlinger's vaccine which was carried out in 1929–30. After his public announcement at the beginning of this year as to the method of preparation of his vaccine, Mr. Spahlinger was invited *and agreed to supply vaccine for independent* test in this country. Arrangements are now in progress for the test concerning which the Ministry is in communication with Mr. Spahlinger ; and it will be undertaken as soon as the vaccine arrives.

THURSDAY, NOV. 3RD

Cancer among Nickel Workers

Mr. DAVID GRENFELL asked the Home Secretary if he would give the House the results of his investigations into the incidence of cancer among men who had been employed at the Mond nickel works ; and whether he was now in a position to recommend precautionary measures for the protection of the men engaged in the processes where previous cases had occurred.—Sir JOHN GILMOUR replied: I am advised that the investigations made earlier in the year, which included a special inquiry by a pathologist, did not establish that the cases of cancer among these men were of industrial origin ; and no substance known to give rise to cancer appeared to be in use at the works. It was proposed that the next step should be an expert examination of a number of the employees, but it was found necessary to postpone this owing to the closing of the works four months ago. I understand that work may be restarted shortly and that it is intended to commence these examinations as soon as practicable, and if the results should indicate that any particular precautions would be of value, the question of putting them into operation would be immediately followed up.

Mr. GRENFELL: Would the Home Secretary not consider the advisability of setting up a Departmental Committee of a similar kind to that which reported last year upon mule-spinners' cancer in view of the evidence already in possession of the local people?

Sir J. GILMOUR: I think that by far the best way is that the examination which has been promised should be undertaken by experts who are more likely to get practical results than any committee.

Mr. GRENFELL: Is the Home Secretary not prepared to give some consideration to the local demand and to do at Cheltenham College and Edinburgh University, qualifying in 1870, when he was chosen house surgeon to James Spence at the old Royal Infirmary. He became an ardent admirer of Syme, learned the new antiseptic technique by watching Lister dressing his cases on Sunday afternoons, and saw Simpson administer chloroform drop by drop on a towel. After leaving Edinburgh, Lediard went to Manchester as house surgeon at the infirmary and then to the Central London Sick Asylum, attending clinical practice at several general hospitals. He took the M.D. Edin. in 1875, and the F.R.C.S. Eng. in 1876.

Through the good offices of Matthews Duncan he then joined Mr. W. B. Page and Dr. J. A. Macdougall in partnership at Carlisle. In 1880 Lediard was appointed assistant surgeon to the Cumberland Infirmary, which he served for 50 years until his resignation in 1930, when he was appointed consulting surgeon and vice-president. During these years his papers on medical, surgical, and ophthalmological subjects were to be counted by scores. Among the more notable of them was an account of a successful case of excision of popliteal aneurysm, in which he observed that excision of part of the popliteal vein did not prevent the good result. He also recorded a successful case of excision of a subclavian aneurysm by Allingham's method. Lediard had a large experience of goitre and of urinary calculus in a district where these diseases were common. As a general surgeon he was held in high esteem by all classes in Cumberland and the border counties. He may truly be said to have introduced the benefits of modern operative surgery to this district, and till late in life he kept in touch with surgical development. It was through him that an X ray apparatus was installed at the infirmary in 1897. During the war he was made a justice of the peace for Carlisle.

Lediard was a widely read man, actively interested in the promotion of the Carlisle Literary Society and the establishment of Tullie House as a centre of the intellectual activities of the city. A man of strong character and independent mind, readily moved by the thought of injustice, he risked on more than one occasion the good opinion of his friends and colleagues in order to fight for what he considered just. In this way, early in his career, he was successful in obtaining the reprieve and ultimate pardon of a man condemned to death for the murder of a country woman near Carlisle. His private kindnesses and benevolences were many, and his high ideal of personal and professional conduct infected those who worked with him. He was a great lover of animals, especially of horses, and to the last drove through the streets of Carlisle in a victoria drawn by thoroughbreds.

Dr. Lediard leaves a widow and a daughter; his elder daughter died while serving as a V.A.D.

(Free to Members.)—WEST END HOSPITAL FOR NERVOUS DISEASES, 73, Welbeck-street, W. A course in Neurology, daily at 5 P.M.—ROYAL WATERLOO HOSPITAL, Waterloo-road, S.E. A course in Medicine, Surgery, and Gynæcology. Afternoons and some mornings.—HOSPITAL FOR CONSUMPTION, Brompton, S.W. A Course in Practical Pathology dealing with Laboratory Methods and the Interpretation of Results. Thurs., 11.45 P.M.—LAMBETH HOSPITAL, Brook-street, S.E. Demonstration of Selected Cases of General Interest by Dr. G. F. Stebbing, assisted by the staff of the hospital. Fri., 2 P.M.—LONDON LOCK HOSPITAL, 91, Dean-street, W. Course in Venereal Diseases. Afternoons and evenings.—CITY OF LONDON HOSPITAL FOR DISEASES OF THE HEART AND LUNGS, Victoria Park, E. All day course in Diseases of the Chest

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE, Hammersmith, W.

MONDAY, Nov. 14th.—10 A.M., Genito-urinary Operations, Skin Department. 11 A.M., Surgical Wards. 2 P.M., Eye and Gynæcological Out-patients. 4.15 P.M., Lecture, Mr. Simmonds: Surgery of the Thyroid.

TUESDAY.—10 A.M., Medical Wards. 11.15 A.M., Surgical Demonstration. 2 P.M., Throat, Nose, and Ear Out-patients.

WEDNESDAY.—10 A.M., Medical Wards, Children's Medical Out-patients. 2 P.M., Eye Department. 4.45 P.M., Venereal Diseases Demonstration.

THURSDAY.—10 A.M., Neurological Out-patients. 11.30 A.M., Demonstration of Fractures. 2 P.M., Eye and Genito-urinary Out-patients.

FRIDAY.—10 A.M., Skin Out-patients. 2 P.M., Throat, Nose, and Ear Out-patients. 4.15 P.M., Lecture, Mr. Roche: Demonstration of Urological Specimens.

DAILY.—At 2 P.M., Operations, Medical and Surgical Out-patients. The lectures at 4.15 P.M. are open to all Medical Practitioners without fee.

OBITUARY

ALFRED BOSTOCK HILL, M.D., D.P.H.

EMERITUS PROFESSOR OF HYGIENE IN THE UNIVERSITY OF BIRMINGHAM

WE regret to announce the death of Prof. Bostock Hill, a leading authority on public health, which occurred at Weybridge on Saturday last, Nov. 5th.

Alfred Bostock Hill was born in 1854. His father Dr. Alfred Hill, the first medical officer of health for the City of Birmingham, was appointed in 1872 after the passing of the Public Health Act of that year, and when he died in 1922 at the advanced age of 95, his two sons, the subject of this memoir and the late Sir Eustace Hill, were both county medical officers of health. Bostock Hill received his general education at King Edward's School, Birmingham, and continued his medical education partly in that city at Queen's College—then the Birmingham medical school with a Royal charter—and partly in Edinburgh, where he qualified in 1876 as L.R.C.P. Edin. and L.M., taking also the L.S.A. diploma. He later obtained a medical degree at Giessen, and made an early start in his career as a sanitarian with the appointment of public analyst to the county of Warwick. In 1879 he became professor of chemistry in Queen's College, took the D.P.H. Camb. in 1881, and shortly afterwards was appointed to the post of professor of hygiene in Mason's College, Birmingham, of which institution Queen's College had now become the medical faculty. On the erection of Mason's College into the University of Birmingham in 1900, Bostock Hill became professor of hygiene and public health in the university, receiving the degree of M.Sc. Birm.

PROF. BOSTOCK HILL

[*Photograph by Elliott and Fry*

The whole of Bostock Hill's life was spent in administering, under different authorities, the regulations for the maintenance of public health. His various appointments make up a lengthy list and he discharged the responsibilities well as is sufficiently shown by his recurrent selection for official posts. At the Royal Sanitary Institute he was a vice-president and acted as an examiner of students; he was president of the Section of State Medicine in 1911 at the annual meeting of the B.M.A. and in the same year was chosen president of the Society of Medical Officers of Health. He was a member of the executive of the British Social Hygiene Council and of the Board of Studies of Hygiene in the University of London, and from 1917 until 1924 was president of the County Medical Officers Association. His long personal experiences led to much desultory but useful publications on many subjects of public health interest. He wrote on water filtration, the purification of sewage, and the spread of scarlatina by milk in different reports, while in his public lectures and addresses he made some useful summaries of the history of sanitary development in this country, and dealt with basic subjects such as the scope of the M.O.H., the evolution of the county health department, and the relation of voluntary effort to State authority in the carrying out of social and sanitary reform.

Dr. R. A. Lyster, a friend of 35 years' standing, an old pupil and assistant, sends us the following appreciation: "One of Bostock Hill's proudest boasts was about the number of his former students and assistants who are scattered over the country—indeed the world—occupying all grades of public health posts, and putting into practice the principles of prevention that they had learned from him. No man has had a stronger influence upon administrative public health in this country. Appointed professor of public health at an early age—he was for a long time the youngest member of the senior staff at Mason's and Queen's College, Birmingham—he was able to teach the essential principles of public health and preventive medicine to generation after generation of medical students. Bostock Hill's lectures will always be remembered by his students. He possessed gifts as a teacher such as are rarely found in medical schools, at any rate in this country. He was, moreover, obviously in love with his subject, and he enjoyed every minute he spent in teaching it.

"In his administrative activities he covered the widest possible field. While his life's work was undoubtedly the creation in Warwickshire of one of the finest of county health departments, he also held local positions as M.O.H. for many years, for the borough of Sutton Coldfield, the urban district of Erdington and the rural district of Castle Bromwich. And no member of the public health service has ever established a greater reputation for soundness of work. Perhaps this was due partly to his scientific training in addition to medicine. As an expert analytical chemist he combined the post of county analyst with that of county medical officer with marked advantage to both.

"Those who knew him best recognised that in addition to Bostock Hill the cultured medical and scientific man, and the sound and experienced administrator, there was also a shrewd and sagacious business mind, and an equable temperament which enabled him to view life from a philosophic standpoint. An attractive and lovable personality, he endeared himself to all his more intimate friends and old students to a degree established by very few teachers and chiefs of departments. None ever hesitated to turn to him for advice and help, and none was ever disappointed. All ranks of the public health service have lost in him a friend, while many mourn personally a teacher and a chief whose passing has made acute their sense of indebtedness to him."

Dr. Bostock Hill married Elizabeth, daughter of Mr. W. H. Barber, of Edgbaston, Birmingham.

HENRY AMBROSE LEDIARD, M.D. Edin., F.R.C.S. Eng., J.P.

Dr. Lediard, who died at Carlisle on Oct. 31st, a few days before his 85th birthday, was the son of Samuel Lediard, solicitor, and Mary Croft Whatley, both of Cirencester, and claimed among his forbears Thomas Lediard, F.R.S. (1685–1743), the historian and biographer of Marlborough. He was educated

ADDRESSES AND ORIGINAL ARTICLES

HÆMATURIA *

BY ANDREW FULLERTON, C.B., C.M.G., M.CH. BELF., F.R.C.S.I., HON. F.A.C.S.

SURGEON TO THE ROYAL VICTORIA HOSPITAL, BELFAST; PROFESSOR OF SURGERY IN THE QUEEN'S UNIVERSITY; EX-PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS IN IRELAND

EVEN in these enlightened days a word of warning on the subject of hæmaturia is necessary, if one is to judge from the number of neglected cases that are constantly coming before the urologist. It cannot be too strongly emphasised that cessation of an attack of hæmaturia is no proof that the cause has been successfully dealt with. On the contrary the most serious disease of the urinary organs, malignant disease, is often characterised by intermittent painless hæmaturia, the intermissions lasting for days, weeks, or even months while the cause is becoming progressively more formidable and less eradicable. Hæmaturia, no matter how slight, should never be lightly regarded and every available means should be used to ascertain its exact cause at the earliest possible moment, lest the insidious onset of a disease curable in its earliest stage should be missed and a life sacrificed by incompetence or neglect. Fortunately, the means of diagnosis are at our disposal, for there is no branch of surgery in which more accuracy and refinement in diagnostic methods is possible, and there is no excuse for the happy-go-lucky methods of the past. The urologist may be compelled to make repeated and exhaustive examinations, involving great labour on his part and possibly much discomfort to the patient, and may even in rare cases have to resort to exploratory operation, but the issue is so important that the medical attendant cannot be considered to have discharged his duty to his patient so long as the source of the bleeding is left in doubt.

In opening a discussion eleven years ago, I gave some statistics of the cases of hæmaturia examined up to that time.[1] I will combine these cases with those subsequently seen, and make reference to certain points not sufficiently emphasised on that occasion.

In pre-cystoscopic days certain general rules were laid down by clinicians to enable the practitioner to make a shrewd guess at the cause and origin of hæmaturia in a given case. These rules may be useful to direct attention to a particular affection or a particular part of the urinary tract, but the ultimate diagnosis must be made by more accurate and scientific methods.

General Considerations

When blood is intimately mixed with the urine it is probable that the source of the hæmorrhage is the kidney. When the blood-stained urine is dark in colour the evidence is still more strongly in favour of a renal origin. Yet there are cases in which these tests are utterly misleading. All we can say with certainty is that blood has been shed in small or moderate quantity, allowing intimate mixture with the urine before clotting has had time to take place. The cystoscope in a renal case may show a red efflux, the smoky or dark colour of the voided specimen being due to the change of oxyhæmoglobin into methæmoglobin by admixture with the acid urine. A couple of examples will show the fallacy of these rough tests:—

A male, aged 56, presented himself with hæmaturia. The specimen passed was dark in colour. The only other symptom was frequency of micturition. Cystoscopy showed a malignant ulcer on the base of the bladder.

A male, aged 56, passed blood intimately mixed with the urine. He passed no clots, and did not complain of pain or dysuria. He had intervals of freedom with clear urine; later, tiny clots began to appear. The symptoms suggested hæmaturia of renal origin. Cystoscopy showed a papilloma of the bladder.

The size and shape of the clots may be of assistance in diagnosis. A long cast of the ureter is sometimes passed; its length and thickness indicate its origin. More frequently shorter lengths are passed. Casts formed in the urethra are thicker and often show constrictions corresponding to those normally present in this canal. Massive clotting suggests bleeding from the bladder or prostate, but primary or secondary hæmorrhage from the kidney after gunshot injuries may be so profuse as to fill the bladder with blood which rapidly clots. The same effect may be seen in civil practice from accidental rupture of the kidney, and in some cases of malignant disease of the kidney.

Frequency of micturition suggests that the site of the hæmaturia is the bladder or prostate, but I have several times seen renal hæmaturia due to new growths or other cause when I have expected to see an enlarged prostate, cystitis, or a bladder tumour. If frequency of micturition and hæmaturia are combined with pain in the glans penis, scalding, and urgency, and if, in addition, pus and mucus are present, cystitis may be suspected, but a positive diagnosis must not be made until malignant growth, tubercle, and calculus have been excluded by direct observation.

Pain in the lumbar region, culminating perhaps in renal colic, suggests an affection of the kidney on that side, but there are cases in which the cause of the pain is a papilloma or a malignant growth at the orifice of the corresponding ureter.

If the hæmaturia is initial, that is, at the beginning of micturition, it probably comes from the prostatic urethra, or possibly from the anterior urethra. Blood issuing from the urethra independently of micturition comes from a source distal to the compressor urethræ muscle. A small quantity may lie in the urethra and form a cast of the canal, which is swept out by the next act of micturition.

The blood may be passed in such small quantities that the microscope may be required to detect it. In every patient suspected of urinary trouble the urine should be centrifugalised and examined microscopically. This is especially necessary in cases of renal or ureteric calculus, when the diagnosis is in doubt. Blood, even microscopical blood, may be entirely absent in some cases of renal, ureteric, or vesical calculus at the time of examination, but repeated examination is very likely to detect it at some period of the patient's illness, and its discovery may help to determine whether the pain is due to stone or some other affection, such as appendicitis. The following case is an illustration:—

In March, 1930, I was asked to see a young man of 27, who, after an action of his bowels, was seized with a sudden severe pain in his right iliac fossa, associated with vomiting. His father, who was a doctor of much experience, was satisfied that the case was one of appendicitis, and urgently requested immediate operation. The patient had no frequency of micturition and an ordinary examination of the urine, such as is carried out at the bedside, revealed no abnormal constituents. There was tenderness in the right iliac fossa, but no rigidity of the abdominal muscles. I was not satisfied with the diagnosis until I had made a microscopical

Appointments

ROBINSON, A. LEYLAND, M.D. Lond., F.R.C.S. Eng., has been appointed Professor of Midwifery and Gynæcology, University of Liverpool.

SINCLAIR, H. M., M.B., Ch.B. Aberd., Certifying Surgeon under the Factory and Workshop Acts for the Maesteg district of Glamorgan.

Vacancies

For further information refer to the advertisement columns

Bolton Royal Infirmary.—Two H.S.'s. Each £125.

Bootle General Hospital, Derby-road.—Anæsthetist. One guinea a session.

Brighton, Royal Alexandria Hospital for Sick Children.—H.S. At rate of £100.

Bristol Royal Infirmary.—Hon. Physician.

Burton-on-Trent [illegible] O. and H.P. Each £150.

Canterbury Boro [illegible] sst. M.O. £350.

Central London [illegible] *Judd-street, W.C.*—Pathologist. [illegible]

Chelsea Hospital for Women, Arthur-street, S.W.—Jun. H.S. At rate of £100. Surgeon. Also Pathologist. £40.

City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E.—Res. M.O. £250. Also H.P. At rate of £100.

Dewsbury and District General Infirmary.—Second H.S. £150.

Doncaster Royal Infirmary.—Cas. H.S. £175.

East Ham Memorial Hospital, Shrewsbury-road, E.—Res. M.O. At rate of £200.

Great Yarmouth General Hospital.—Two H.S.'s. Each £140.

Hampstead General and N.W. London Hospital, Haverstock-hill, N.W.—Surgeon to Out-patients. Also Anæsthetist. £25.

Hospital for Sick Children, Great Ormond-street, W.C.—Part-time Jun. Cas. O. At rate of £150. Also H.P. and H.S. Each at rate of £100.

Infants Hospital, Vincent-square, Westminster, S.W.—H.P. £75.

Ipswich, East Suffolk and Ipswich Hospital.—H.P. and Two H.S.'s. Each at rate of £120.

King Edward [illegible]—Pathologist. £170.

Leamington Sp [illegible] *pital.*—Hon. Surgeon for Diseases [illegible]

Leicester Royal [illegible] esthetist. At rate of £250.

Lister Institute of Preventive Medicine, Chelsea Bridge-road, S.W. [illegible] Fellowship in Bacteriology. £500.

[illegible] *natorium.*—Asst. Res. M.O. £200.

[illegible]—Part-time M.O.'s for Training Ship, *Exmouth*; and Stifford and Grays Children's Home. At rate of £200 and £150 respectively.

Lowestoft, St. Luke's Hospital.—Res. Asst. M.O. £350.

Manchester Babies' Hospital, Burnage Lane, Levenshulme.—Sen. Res. M.O. At rate of £125.

Plymouth, South Devon and East Cornwall Hospital.—H.P. and H.S. At rate of £120 and £100 respectively.

Poplar Hospital for Accidents, East India Dock-road, E.—Sen. Res. O. £200.

Preston, Lancs, Biddulph Grange Orthopædic Hospital.—Sen. H.S. Also Jun. H.S. At rate of £250 and £150 respectively.

Princess Elizabeth of York Hospital for Children, Shadwell, E.—Res. M.O. £200.

Reading, [illegible]—H.S. £150.

Rochdale [illegible] H.S. £200.

Royal Fr [illegible] .*C.*—Cas. O. At rate of £150. Dist. Obstet. Asst. At rate of £100. Res. H.P.'s, H.S.'s, and Res. Anæsthetist, &c. Also First H.P.

Royal Nationa [illegible] *234, Gt. Portland-street, W.* H.S. for [illegible] t rate of £150.

Royal Northern [illegible] *N.*—Med. Reg. £100.

Royal Waterlo [illegible] *and Women, Waterloo-road, S.E.*—H.S [illegible]

South-Eastern [illegible] *Sydenham, S.E.*—Jun. Res. M.O. At [illegible]

South Shields, Ingham Infirmary.—Jun. H.S. £150.

Tilbury Hospital.—Med. Supt. £200.

University College Hospital, Gower-street, W.C.—Hon. Clinical Asst., Hon. Asst. Radiologist. Also Hon. Orthodonist and Dental Surgeon.

Wakefield Mental Hospital.—Asst. M.O. £350.

West London Hospital, Hammersmith-road, W.—H.P. and Two H.S.'s. Each at rate of £100.

Willesden General Hospital, N.W.—Cas. O., H.S., and H.P. All at rate of £100.

Winchester, Royal Hampshire County Hospital.—H.S. At rate of £125.

York County Hospital.—H.P. £150.

The Chief Inspector of Factories announces a *vacancy* for a Certifying Factory Surgeon at Rothwell (York).

ROYAL SANITARY INSTITUTE.—A sessional meeting of this institute was held at Durham during last week-end. On Friday the modern construction of infectious diseases hospitals was considered, after an address by Dr. J. A. Charles, deputy medical officer of Newcastle-on-Tyne. The subject of central hospitals with resident medical staffs was discussed, and Mr. T. C. Benfold, vice-chairman of the Durham county health committee, said the best interests of the community would be served by a full-time medical staff in a central hospital. "We ought to get away from the part-time medical officer," he said. "A person who is a local practitioner and at the same time a medical officer to a hospital is unlikely to give the best results to either hospital or patient. A local practitioner has first and foremost to look after his own patients before he spends his time at the hospital. A person who is making a livelihood from family patients has got to look there first. We want the best equipped medical men to deal with the hospitals."

seminal vesicles, and the urethra, including the meatus externus, were all infected with tubercle. I believe this is the normal direction of spread in the male. In the female the primary focus is always in the kidney. Very rarely does the bladder escape in tuberculosis, and the hæmaturia resembles in character that found in bad cases of cystitis. The blood comes for the most part from ulcers on the bladder wall. Severe hæmaturia from the kidney is not, in my experience, frequent. From the erosion which takes place at the apices of the pyramids in these cases one would expect frequently to see more bleeding of renal origin, but gross hæmorrhage is rare. A patient with severe scalding, great frequency of micturition, and hæmaturia, especially noticeable at the end of micturition, should always be suspected of tuberculosis, even if his colour and nutrition are good. Many cases of tuberculosis of the kidney and bladder run an afebrile course for a long time, and seem to keep up an appearance of well-being for months or even years.

Renal and Ureteric Calculus (*140 cases*).—One of the most frequent causes of renal hæmaturia is renal or ureteric calculus. Out of 206 cases seen, hæmaturia was noted in 140 or just under 70 per cent. The sharp spicules and knife-like edges found on some of these calculi are very likely to lacerate the mucous membrane of the pelvis of the kidney and ureter and the apices of the pyramids, and smart hæmorrhage is frequently seen. The bleeding is not, however, so severe as that in injury or new growths of the kidney. Quite frequently it is entirely absent, or may be in such small amount as to require the microscope for its detection. I wish to emphasise the fact that a patient may have urine entirely free from albumin, pus, and blood, and yet may have a calculus lodged in the pelvis of the kidney or arrested in the ureter. The only symptom may be pain, often of the well-known type known as renal colic. One example out of several will suffice:—

I recently saw a woman, aged 41, with severe renal colic on the left side. The urine was free from albumin, pus, and blood. The only physical sign was a unilateral diuresis on the affected side. I removed a calculus with crystalline projections, half an inch in diameter, from the pelvis of the left kidney.

On the other hand hæmaturia may be the only sign.

I have under my care at present a woman, aged 55, who has suffered for over a year from painless hæmaturia without any other sign or symptom. In August last I removed a large calculus from the pelvis of the left kidney, and four months later 14 calculi from the pelvis of the right kidney.

The two cardinal signs of renal calculus are renal colic and hæmaturia, and one or both may be entirely absent. Vomiting is frequently present. In these days radiography will often detect the smallest calculus, but in my earlier work, especially in the country, I had to depend on other methods for diagnosis. A history of renal colic with or without blood, the presence of pus, the presence of albumin, and a unilateral diuresis with a diminution of the specific gravity of the urine on the affected side afforded, in those days, the evidence upon which I often operated for stone. By far the most common ingredient of the calculus in my cases has been oxalate of calcium; phosphates come next, and uric acid or urates last of all.

Renal Hæmaturia of Undetermined Origin (*87 cases*). I now come to a group of cases, 87 in number, in which, often after the most careful urological examination, including, in a few, actual exploration of the kidney, I have been unable to state definitely what was the cause of the bleeding. Some of them have been followed up for years without any definite evidence of deterioration of the patients' health, and some have drifted no doubt into the hands of other surgeons who may have been able to diagnose them correctly. One or two of them have, I regret to say, subsequently shown signs of malignancy which might possibly have been recognised by more detailed examination. A certain number of them must, however, be placed in the category of what is known as renal epistaxis, renal hæmophilia, essential renal hæmaturia, or symptomless renal hæmaturia. The hæmorrhage in these cases of renal epistaxis is more or less severe, more or less persistent, and is seen to issue from one ureter. No gross changes in the kidney can be found to account for it. It has been attributed to passive congestion, circumscribed or diffuse fibrous changes, disturbances of the vasomotor and sensory nerves, multiple microscopic calculi of the papillæ, a varicose condition of the vessels of the papillæ, adhesions, microbic infections, and nephritis. I have never removed a kidney which appeared to me to be healthy, even if it was bleeding pretty profusely, and I have often seen the bleeding cease after the operative procedure adopted to explore the kidney. This conservative attitude was strengthened by a case I saw in July, 1908, at the Royal Victoria Hospital:—

The patient was a sailor, aged 30, who, two months after a fall on his right side on board ship, noticed that his urine was smoky. Prof. Rovsing, of Copenhagen, found blood issuing from the *right* ureter. X ray examination was negative. The right kidney was explored and nothing was found but adhesions to surrounding parts. The bleeding recurred, and I saw him on his return to Belfast. On cystoscopic examination blood was now seen to come from the *left* ureter. The specimen obtained from the side operated on by Prof. Rovsing was absolutely normal. Three years later I again cystoscoped the patient, who had been bleeding off and on since my first examination. The blood was now coming from the right side (the side operated on). I heard from him in 1923 to the effect that he remained well after his last visit to me until his ship was blown up by a submarine in 1917, and that after 24 hours' exposure in an open boat before being rescued he had a return of the bleeding and was admitted to the Glasgow Royal Infirmary, where operation was suggested but declined by the patient. He came home in a few weeks, and remained at home for some months. The bleeding, having lasted for 18 months ceased, and he remained well for some years. I saw him again in June, 1923. He was also seen at this time by Dr. Boyd Campbell, who found his urine normal and his heart and blood-vessels healthy. He again attended in February, 1926 (18 years after his first visit to me), with another attack of hæmaturia. On this occasion blood was issuing from the *right* ureter. This remarkable case shows the necessity for caution in dealing with a case of symptomless hæmaturia.

I had another patient under observation for seven years, during which time he had many attacks of bleeding without any serious deterioration of his health. I have not noticed in any of these cases the phenomenon which I have termed unilateral diuresis. The occurrence of this type of hæmaturia is sometimes urged as an excuse for temporising. Long experience, however, has taught me to look upon all cases of hæmaturia as serious and possibly dangerous, and to exhaust every method of diagnosis available before assuring the patient that he can look upon the discharge of blood from his urinary organs with complacency.

Pyelitis, generally Associated with Cystitis (*54 cases*). The essential feature of pyelitis is the presence of pus in the urine on one or both sides. The most usual organism present is the *Bacillus coli communis*, but I have seen staphylococci, streptococci, enterococci, and other organisms. Though severe hæmorrhage may take place, the amount of blood present has, as a rule, been small and not a dominant feature in the clinical picture. In acute cases the temperature is raised, and there may be tenderness or enlargement examination of the urine. This showed a number of red blood corpuscles. Operation was deferred, and next day a radioscopic examination by Mr. P. T. Crymble demonstrated a small shadow medial to the right ischial spine. A diagnosis of ureteric calculus was made and was confirmed by the passage, in a fortnight's time, of a small irregular stone composed of oxalate of calcium. The detection of microscopical blood in this case prevented the performance of an unnecessary operation.

In a case of hæmaturia, microscopical examination, especially if it can be carried out in the intervals between the attacks of bleeding, may be helpful in determining the cause. Mention need only be made of the presence of renal casts, cells from the kidney, ureter, or bladder, portions of growth, pus cells, crystals, and micro-organisms.

Diagnosis

Correct diagnosis of the cause of hæmaturia is possible in the large majority of cases. As a rule the urethroscope or cystoscope will indicate the source of the bleeding when it occurs in the urethra or bladder, and in the case of the kidney or ureter will demonstrate the side affected if bleeding is taking place at the moment. In the intervals between attacks, however, the urologist may have the greatest difficulty in ascertaining the cause. It is wise, therefore, to examine the patient during an attack, when the side affected will be apparent, but this does not mean that the urologist's labours are at an end. He must endeavour to discover the exact lesion and its situation. Blood coming from one ureteric orifice, for instance, may come from a lesion of the ureter, and the catheter must decide which part of the ureter is affected. It is desirable in all cases to take specimens from the pelvis of the kidney and from the ureter near its termination in the bladder, to avoid the error of mistaking bleeding from the ureter for renal hæmorrhage. Alteration in the character of the secretion or the presence of abnormal constituents in the urine may give valuable information. A tumour in the lumbar region or pain on one side will direct attention to the affected organ, but of themselves these signs and symptoms may not be sufficient to establish the diagnosis. Pyelography, intravenous or retrograde, will in a large proportion of cases, by demonstrating some departure from the normal in a ureterogram or pyelogram, give the necessary clue, but cases will arise in which the diagnosis still remains in doubt. In these doubtful cases there is much to be said in favour of an exploratory operation. This consists in inspecting the kidney, making an opening in the pelvis to examine the calyces and papillæ, and if need be, making an incision into the parenchyma of the organ.

A Series of Cases

Looking over my notes I find, grouped under the heading of hæmaturia, 1208 cases out of a total of 3400 cases seen. Thus more than a third of the patients presenting themselves to me for urological investigation have suffered at one time or another from hæmaturia. I am satisfied that in many of the remainder blood would have been found at some period if it had been carefully sought. This applies particularly to calculus, enlarged prostate, cystitis, tubercle, and new growths, in which at the time of examination blood may not have been present. I have, for instance, seen cases of renal calculus in which blood was entirely absent at the time of examination, and I recently examined the urine in a case of papilloma of the bladder during an interval of freedom from bleeding and found no trace of blood, even on microscopical examination. Repeated examinations must therefore be made in all urological cases, and the microscope should always be used lest small traces of blood should be missed. From the statistics I have given, it is obvious that hæmaturia is one of the most important, if not the most important, sign of disease of the urinary tract.

In the accompanying Table the cases are grouped according to the region affected; under each heading they are arranged in order of frequency. This has disadvantages, but is convenient for my present purpose :—

Table showing Cases of Hæmaturia

KIDNEY (605 cases)		Cases.
Tuberculosis of kidney (generally involving bladder)		153
Renal and ureteric calculi		140
Renal hæmaturia of undetermined origin		87
Pyelitis (generally associated with cystitis)		54
Injuries to kidney—		
Gunshot wounds	42	50
Contusions and lacerations	8	
Nephritis		38
Renal tumours and cysts		36
Hydronephrosis	9	15
Pyonephrosis	6	
Renal colic (cause ?)		14
Movable kidney		7
Accessory renal artery		3
Horseshoe kidney		2
Oxaluria		2
Henoch's purpura		1
Hæmophilia		1
Hæmaturia after pyelography		1
Perirenal sarcoma		1

URETER (6 cases)	Cases.
Injury to ureter	5
New growth in ureter	1

BLADDER (470 cases)		Cases.
Cystitis		190
Tumours of bladder—		
Simple papillomata	65	135
Malignant growths	68	
Fibromyoma	1	
Rhabdo-sarcoma	1	
Injuries to the bladder—		
Bladder injuries in warfare	54	57
,, ,, ,, civil practice	3	
Vesical calculus		51
Ulceration of bladder (not due to tubercle or new growth)		16
Ruptured vessels of bladder		8
Tuberculosis of bladder secondary to tuberculosis of epididymis		5
Bilharzia hæmatobia infection of bladder		4
Obstruction at neck of bladder		1
Diverticulum of bladder		1
Malignant growth in pelvis ulcerating into bladder		1
Foreign body in bladder		1

PROSTATE (115 cases)	Cases.
Enlarged prostate (including malignant disease)	107
Prostatitis and prostatic abscess	8

URETHRA (12 cases)		Cases.
Polypus of anterior urethra	3	4
,, ,, posterior ,,	1	
Ruptured urethra		3
Calculus in urethra		2
Periurethral abscess		1
Malignant growth of urethra		1
Urethritis		1

AFFECTIONS OF THE KIDNEY

Tuberculosis of the Kidney (153 cases).—Tuberculosis of the urinary tract is very common in the north of Ireland. Some years ago I went into the figures of cases cystoscoped in hospital and private practice and found that nearly 10 per cent. had urinary tuberculosis and in 75 per cent. of these hæmaturia was present. In the overwhelming majority the primary focus in the urinary tract was in the kidney. In my experience tuberculosis of the bladder arising secondarily to deposits in the vesiculæ, prostate, and epididymis is comparatively rare. If the ureteral catheter is used in all cases of tuberculosis of the vesiculæ and epididymis the surgeon will be surprised to find how often the kidney is affected. I have seen a case of descending tuberculosis in which the right kidney and ureter, the bladder, the prostate, the great relief from denervation of the kidney. I have not seen these movements of the lips of the wound in the pelvis described in the literature. In two cases recently I have been able to demonstrate them to bystanders. I should like confirmation of these observations by those who have frequent opportunities of operating on the kidney.

Movable Kidney (*7 cases*).—It is well known that hæmaturia may take place during Dietl's crises, which result from torsion of the pedicle of the kidney. In these cases, in addition to the interference with the circulation of the kidney, there may be kinking of the ureter, and hydronephrosis is a frequent complication. The kink is well seen by pyelography, and is usually sigmoid in shape.

In one case, a woman, aged 42, with fairly continuous hæmaturia for two months, cystoscopy showed blood-stained urine issuing from the left ureteral orifice, and pyelography demonstrated the shadow of the pelvis of the kidney lying close to the pelvic brim. The ureter at its upper part was bent like a whip, with the convexity of the bend upward, and the kidney hung like an appendage from its outer extremity.

Hæmaturia in these cases of movable kidney is not as a rule profuse, and is best treated by rest in the recumbent position followed by nephropexy.

Accessory Renal Artery (*3 cases*).—The symptoms in these cases are due to the contact which an abnormal renal artery, accompanied perhaps by a vein, makes with the ureter. A vessel, in passing to the lower pole of the kidney, crosses the upper end of the ureter, "bow-stringing" it, as Mr. Hurry Fenwick says. Hydronephrosis is a frequent result. In one of my cases an artery the size of the temporal was accompanied by a still larger vein which was completely occluded by what appeared to be fibrous tissue. The occlusion of the vein may have caused congestion of the affected segment. The pelvis of the kidney and the calyces were much dilated. It is well to bear in mind that the arteries of the kidney are end-arteries, though the veins anastomose. Ligature of an artery going to the kidney causes necrosis of the area of kidney supplied by it. Sepsis in the wound may end in sloughing of the necrosed segment, and possibly secondary hæmorrhage.

Horse-shoe Kidney (*2 cases*).—The symptoms in these cases resembled those of movable kidney, and were no doubt due to malposition of the organ with kinking of the ureter. These kidneys are especially predisposed to hydronephrosis, calculi, tubercle, and infections. The diagnosis may be made by a careful study of the pyelograms taken alternately on both sides with a suitable interval between. Double pyelograms taken at the same sitting are not devoid of risk.

Oxaluria (*2 cases*).—I have cystoscoped two cases of oxaluria in which the symptoms were attributed to the presence of numerous crystals of calcium oxalate in the urine. In one of them severe renal colic was complained of, but no stone was found at operation.

Henoch's Purpura (*1 case*).—I have cystoscoped one case of this affection. There were ecchymotic spots on the body, arms, and legs, particularly about the joints. Hæmatemesis and moderate pyrexia were present. On cystoscopy, blood-stained urine was seen issuing from both ureters. The urine contained blood casts and granular casts.

Hæmophilia (*1 case*).—I have cystoscoped one case of hæmophilia :—

The patient was a young man, aged 24, with a typical family and personal history. He complained of pain in the right lumbar region, and passed clots of blood. On cystoscopy the bladder was seen to be healthy. Blood-stained urine was obtained from the right ureter, and clear urine from the left.

Hæmaturia after Pyelography (*1 case*).—I have seen one case illustrating the risks of pyelography :—

The patient, a girl of 17, complained of pain in the region of the left kidney. A colleague acting for me took a pyelogram of the left kidney, using 12 per cent. solution of iodide of sodium, introduced with the usual precautions. The patient was seized with acute pain on the table and became faint. She passed blood in her urine for three weeks, with moderate fever. The pyelogram showed a kink of the ureter at its junction with the pelvis of the kidney. Before cystoscopy her urine has been free from blood, pus, and albumin. I saw her about a month later, when her urine contained a fair amount of pus, a few red blood corpuscles, and a trace of albumin. About five weeks after the pyelography the kidney was explored. It was somewhat larger than normal, and the capsule was seen to be completely stripped and separated from the cortex by a thin layer of fluid. On incising the capsule blood-stained serous fluid escaped. The underlying cortex was paler than normal. Beyond some thick adhesions at the lower pole of the kidney nothing abnormal was found, and the kidney was replaced after stripping back the capsule and denuding the posterior abdominal wall of fat to promote adhesions. The patient made a good recovery.

Perirenal Sarcoma (*1 case*).—In this case a perirenal sarcoma had compressed the right ureter and given rise to a hydronephrosis of the corresponding kidney. This became infected, and blood and pus were obtained from the right ureter after the catheter had passed an obstruction about 4½ inches up. Operation revealed an inoperable retroperitoneal growth which on section was reported to be a large round-celled sarcoma.

(*To be concluded*)

TROPICAL ULCERS:

A QUICK AND SUCCESSFUL METHOD OF TREATMENT BY EXCISION AND SKIN GRAFT

BY CLIFFORD JAMES, M.B. N.Z., D.T.M. & H. LOND.
F.R.C.S. EDIN.

MEDICAL SUPERINTENDENT, METHODIST MISSION HOSPITALS,
CHOISEUL, BRITISH SOLOMONS

THE two outstanding features of ulcers as they are found on this island are (1) their obstinate resistance to ordinary forms of treatment, and (2) the ease with which the scar formed on healing breaks down again. The unsatisfactoriness of out-patient treatment as the cases came to hospital, week after week, and the disappointment when the scar broke down and the whole process had to be gone through again, demanded some change in treatment. Available books offered various methods of treatment, but the recorded results were not encouraging. Surgery suggested itself, and it was by repeated attempt after each failure that eventually a degree of success was attained. In the belief that it may be of help to others, I wish to record these attempts.

The ideal aimed at was to find a simple method which would replace the ulcer by healthy skin in a minimum of time and at a minimum of expense. The ulcer was considered healed when the area was completely covered by epithelium, as judged by careful observation and by the fact that a dry gauze dressing did not adhere, but was dry and unstained on removal.

Complete success was entered if the ideal was reached, the type of patient and the site of the ulcer being taken into consideration.

Partial success was obtained if the ideal was reached but the time taken, while much shorter than that taken by lotions and dressings, was longer than that taken in a completely successful case—e.g., through a minor degree of sepsis, or through some foolishness on the part of the patient.

of one or both kidneys. It is unwise in the febrile stage to carry out any instrumental examination. After such an examination the temperature is likely to shoot up, and rigors may occur. Every case should be radiographed if the pyuria persists. I have more than once seen a patient treated for months by vaccines for pyuria due to an unsuspected stone in the pelvis of the kidney.

Injuries to the Kidney (*50 cases*).—Injuries to the kidney include gunshot wounds and the contusions and lacerations which are more familiar in civil practice. There were 42 cases of gunshot wounds, and I have dealt so exhaustively with these in a paper[2] published during the war that I need only refer to them very briefly. The hæmaturia may be microscopic, moderate, or profuse, and may be primary or secondary. If the hæmorrhage is profuse the bladder may be filled with clots, requiring an evacuator, or even cystotomy for their removal. A large perirenal hæmatoma may be present which can be felt as a tumour, and may be a sign of importance in certain transverse wounds in which it is not easy to locate the kidney affected. Secondary hæmorrhage took place in nine cases out of the 42. In eight of these a nephrectomy was considered necessary, and of these three died. In the ninth case the patient died from other wounds.

There were eight cases in civil practice in which contusions or lacerations were diagnosed, and in seven of these the symptoms were sufficiently mild to admit of cystoscopic examination. In the eighth case I removed the kidney without cystoscopic examination as an emergency operation. A comparatively slight strain is sometimes sufficient to injure the kidney and give rise to considerable hæmaturia. I have seen this in a patient who slipped on a plank and apparently bruised his kidney in the effort to right himself. Forced lateral flexion of the trunk was, in two of the present series, sufficient to cause considerable bleeding. In one a perirenal hæmatoma was present; blood was seen issuing from the ureteral orifice of the affected side, and clots were present in the bladder. The injury appears to be due to crushing of the kidney between the ribs and the iliac bone on the concave side. Blows and run-over accidents account for most of the cases, and the injury to the kidney is often complicated by damage to other important organs.

It is important to know when to interfere in cases of renal injury. It is almost certainly fatal to operate on a blanched patient. Blood transfusion followed by immediate operation may save the patient's life.

Nephritis (*38 cases*).—These cases belong to the domain of the physician rather than that of the surgeon, and their chief feature from a cystoscopic point of view is the presence in many of them of blood on both sides. In all some other sign or symptom was present, such as casts and albumin in the urine when the bleeding was for the moment absent, cardiovascular changes, albuminuric retinitis, œdema of the face and extremities, or some other indication of acute or chronic nephritis. Some of these cases have cleared up completely and have apparently quite recovered.

Renal Tumours and Cysts (*36 cases*).—In all cases of renal hæmaturia without other signs, the practitioner must have in his mind the possibility of malignant disease of the kidney. Of the tumours found at operation, hypernephromata were by far the most numerous. Other growths and cysts included malignant adenoma, sarcoma, malignant growths of the abdomen involving the kidney by continuity, a case of hydatid cyst which I saw in France, congenital cystic kidney, a rare form of cystic kidney removed from a child aged two years, and one or two cases judged to be inoperable. In the hydatid cyst and the cystic kidney removed from the child aged two years the bleeding, though noticeable, was neither persistent nor serious. In one case of congenital cystic kidney the bleeding was so profuse as to threaten the life of the patient. In several of the cases of hypernephroma the bleeding was considerable and clots were passed. Some of them suffered from renal colic, and others had no other symptom but painless hæmaturia, at any rate in the early stages. The appearance of a tumour in the side is evidence that the disease is in an advanced stage. Pyelography is a most valuable means of differential diagnosis between tumour and other renal conditions giving rise to hæmaturia, and should never be omitted in a doubtful case. Distortion of the pelvis, filling defects, and obliteration of calyces will convey much information to the practised eye and may indeed settle the diagnosis. If still in doubt, I am in favour of an exploratory operation. It must be borne in mind that many cases of malignant disease of the kidney run their course without hæmaturia. The responsibility of the practitioner in these cases is not so heavy as in those which give early warning of their presence by attacks of bleeding, separated, it may be, by long intervals of freedom. The occurrence of hæmaturia is too valuable a sign to be neglected.

Hydronephrosis and Pyonephrosis (*15 cases*) are conditions in which the pelvis and calyces are dilated from back pressure (hydronephrosis) and in which infection with pus formation (pyonephrosis) is likely to take place. The chief signs and symptoms are pain, sometimes developing into renal colic, with vomiting and a tumour in the lumbar region which varies in size or even disappears at times. When infection takes place, the temperature may rise, but one sees cases of pyonephrosis without fever. Hæmaturia is not a cardinal sign but was present in 15 cases. The urine from the affected side is usually of lower specific gravity than that obtained from the opposite kidney. At times no fluid can be obtained owing to the block. In one case inspissated blood was seen by the cystoscope to be squeezed out from the ureter of the affected side like ointment from a tube. Bleeding had evidently taken place at some time into the sac of the distended kidney. Intravenous pyelography may show the distended calyces or pelvis, but if the parenchyma of the kidney is seriously damaged no shadow will be seen. Injections of opaque solutions by ureteral catheter will show the degree of distension, and will outline the size and shape of the pelvis and calyces. The diagnosis is thus easily made.

Renal Colic without Obvious Cause (*14 cases*).—There are cases of renal colic with hæmaturia in which it is difficult or impossible to find a cause. Some of these are no doubt due to undetected calculi, or calculi which have been unconsciously passed. There may be, as L. Casper suggests, spasm of the ureter comparable with that of the œsophagus in hysterical people. I have seen the lips of the wound made into the pelvis of the kidney for exploratory purposes, or for the removal of a stone, slowly curl outwards and return to the resting position during observation, and especially in response to a slight stimulus, and have thought that this was due to increased irritability of the pelvis, possibly from some unexplained nervous cause. In one case of this sort the patient obtained

Curettage Followed by Delayed Graft

No. of case.	Size of ulcer in inches.	Site.	Type of ulcer.	Healing time in days.	Result.	Type of graft.	Remarks.
8	3 × 1½	Mid. ⅓.	Ac. prog. with septic subcutaneous channels.	39 + 16 = 55	Part. suc.	Thiersch.	Thorough curettage was followed after 39* days by Thiersch graft. Eighteen months after, graft not detectable.

Excision Only

No. of case.	Size of ulcer in inches.	Site.	Type of ulcer.	Healing time in days.	Result.	Type of graft.	Remarks.
12	3 × 2 2 × 1½	Right knee. Left „	Ac. prog. „ „	— —	Non-suc. „	— —	Patient fell from verandah. Abrasions were followed by acute spreading ulcers. Excision was done, but was insufficient. Patient died of toxæmia 18 days after excision during my absence.

* This period of 39 days was unduly long. At the time when grafting was indicated it was not convenient for me to do it.

Ac. prog. = Acute and progressive. Ac. stat. = Acute, but stationary. Comb. = Combined, progressive in one area, but stationary in another area. Ch. sep. = Chronic septic. Ac. sep. = Acute septic. Ant. = Anterior. Int. = Internal and lateral. Ext. = External and lateral. Mid. ⅓ = Middle ⅓. Lr. ⅓ = Lower ⅓. Comp. suc. = Completely successful.

grafts, absolute hæmostasis is not necessary. In Case 33 the seeds were placed literally in a "stream of blood," nor did the bleeding quite stop until the patient had been back in bed for three hours. Calcium chloride gr. 1 in 100 m. of water intramuscularly stopped it. The grafts in this case adhered in toto.

The graft which has been most successful is the *seed graft.* The sterile towel covering the prepared skin area is removed and a darning needle with a sharp point is jabbed gently into the skin. A "tent" of epidermis is lifted. A razor blade fixed in a pair of Kocher's forceps incises this tent by cutting just below the needle. This small seed is placed on the new ulcer bed, more seeds being removed until the ulcer is covered. One soon becomes adept at this little manœuvre, and what promised to be a long task is quickly finished. These seeds may be applied so that the bed is completely covered, or there may be a space between individual grafts. The closer together the grafts are applied, the shorter is the time of healing, but the difference in time is not great. Even if at first there is pale skin between seeds, in one to two months the whole area is black. The skin thickness varies in individuals, and so the depth of the seed will vary. The optimum is the depth of a Thiersch graft. So long as the area from which the seed has been taken is grey in colour and points of hæmorrhage appear—though minute areas of yellow fat are frequently visible—and the raw area of the seed is not yellow, the seed will be suitable. With practice, these seeds can be greatly increased in size.

The graft is carefully covered by paraffin wax gauze, sterilised by steeping in lysol for 30 minutes. (Coarse mosquito-netting boiled in hard wax and allowed to dry can be used.) With a swab damped in saline, the seeds are gently but firmly pressed on to the base, any blood is soaked up, and a piece of dry gauze is applied over the wax gauze. Some cotton-wool is teased and shaped so as to fit accurately over the graft, giving equal pressure. Over this is placed a layer of wool well soaked in equal parts of glycerin and red lotion, which soaks the wool pad. More wool is applied and a bandage is bound gently but firmly over all. The same dressing is applied to the denuded area on the thigh, and the patient is returned to bed with his foot on a pillow. Latterly in some cases I have been putting over all one 3 in. plaster bandage, for its effect in keeping the patient to his bed. Where an ulcer is situated over the malleoli or anterior of the ankle-joint, plaster is advisable, a window being cut out at the first dressing two days after operation.

After-treatment.—On the second day the wool is very gently removed by soaking it in glycerin lotion. Everything is removed down to the wax gauze. This is easily done without disturbing the grafts. If everything is dry

TABLE II.—SUMMARY OF CASES

Excision Followed by Immediate Skin-graft, by Seeds, Thiersch, or Combination of Both

ADVANTAGES OF EXCISION AND SKIN-GRAFT

(1) Excision removes the ulcer and the scar tissue, which contains dormant organisms. (2) Skin-grafting replaces the ulcer and scar tissue (which would be formed were the ulcer to heal naturally) by skin, which soon functions normally except for diminution in sensation and a certain dryness due to lack of sebaceous material. The graft becomes surprisingly soft and pliable. This is accomplished in a very short time; the average of the 41 cases where the time could be ascertained was 13 days for complete epithelialisation. (3) The expense is small,
inexpensive, and the instruments
4) The technique is simple and can
ny doctor who will observe the
cleanliness and asepsis. (5) The

roved successful in producing a good reaction.
general treatment of all ulcer cases by quinine, cod-liver oil, compound syrup of phosphate of iron, and milk when possible. The standard case noted above was also on this routine.

SUMMARY

The ideal of a simple method which would heal a tropical ulcer by replacing it with normal, or nearly normal, skin in a minimum of time and at a small expense has been sought. A satisfactory and surprisingly successful method has been found in excision and skin-graft, seeds being the surest method of graft and the easiest of application. In suitable cases Thiersch grafts can be combined with seeds.

The results of this method in 45 cases are: completely successful, 91 per cent.; partially successful, 7 per cent.; non-successful, 2 per cent. Average time taken for complete epithelialisation of the area 13 days. The method of treatment described is suitable for all states and groups.

Christie Cancer Hospital.—A week or so ago Lord Derby opened the new Christie Cancer Hospital and Holt Radium Institute at Withington, Manchester. Hitherto the Cancer Hospital has been housed in Lorne-street, and the Radium Institute in Nelson-street, a few hundred yards away; the two are now linked together. There are 104 beds, 12 of them in separate rooms for paying patients. The two theatres have an intermediate chamber in which one outfit of equipment will be stored, and they will be served by one anæsthetising department. A nurses' home has been provided, and the hospital is surrounded by spacious gardens.

ADRENAL NEUROBLASTOMA

A CASE WITH METASTASES CAUSING BLINDNESS

By Frank W. Law, M.D. Camb., F.R.C.S. Eng.

Adrenal neuroblastoma—also variously called suprarenal sarcoma, adrenal neurocytoma, and malignant medullary hypernephroma—is a rare disease of childhood, which usually presents a typical syndrome which renders it easy of diagnosis in spite of its rarity. While much discussion has ranged round the actual nature of the tumour, the clinical aspect of the condition has been agreed upon for many years, though the various manifestations of the disease caused considerable confusion until Frew,[1] in 1911, showed that the cases were divisible into two groups, showing differing clinical pictures, according to the side of the body upon which the primary lesion was located.

Cohn,[2] in 1894, described a case which he called "medullary sarcoma of the right suprarenal, with secondaries"; this occurred in a female child of 9 months, who died in five weeks. He describes the existence of a palpable tumour in the right loin, together with right proptosis, and secondary deposits in the skull; no blood count is given. In an important paper in 1901, Pepper[3] reported the occurrence of "congenital sarcoma of the liver and suprarenal" in a child who died at six and a half weeks; he describes five similar cases, all of which fall in the group under consideration. But in addition he tabulates 46 further cases of so-called "primary sarcoma of the suprarenal gland"; since these include patients up to the age of 68 years, and since in only one of the whole series is there mention of cranial metastases, it is evident that many widely differing types of abdominal tumour are represented. Bruck,[4] in 1905, and Ogden and Matthews,[5] in 1906, described cases of round-celled sarcoma of the suprarenal; each of these papers is of interest since the writers describe the occurrence, for apparently the first time, of the hæmorrhagic streak in the skin of the lower eyelid. In the latter paper there is mention of a blood picture indicative of a secondary anæmia.

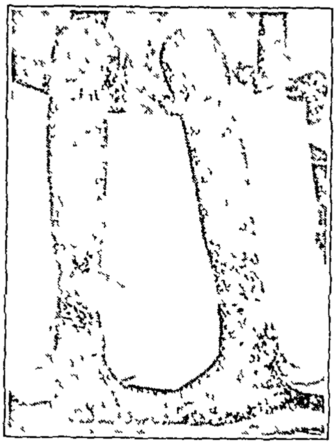
In 1907 Hutchison[6] gave a careful account of sarcoma of the suprarenal with metastases in cranial bones. He described seven new cases and three old, occurring in children aged from 9 months to 9 years, of whom seven were male and three female, and mentions, as the first indication of the disease, swellings on the skull. There was a high degree of secondary anæmia, but, he states, no leucocytosis; a tumour was palpable in five cases, and was situated on the right side in four and the left side in six. He mentioned, in the consideration of the differential diagnosis, infantile scurvy and chloroma (the former evidently on account of the hæmorrhagic streak); also that there were no sexual changes. This latter fact is evident, since the tumour is situated in the medullary portion of the gland; such changes occur in cortical tumours, as has been so well described by Bullock and Sequeira,[7] Guthrie and Emery,[8] and Collet.[9] Glynn,[10] in 1911, gave an excellent review of published accounts of cortical as well as medullary suprarenal tumours, furnished with a comprehensive bibliography.

Our knowledge of the disease was amplified and clarified, as has been mentioned, by Frew in 1911, who discussed Hutchison's paper, and described a large series of cases; his main thesis was that the and there is no sign of sepsis, a fresh dressing is applied and the ulcer left for a further three days, or longer, depending on one's certainty that no sepsis is present. The wax gauze can be removed after a week. If at any dressing there is the slightest sign of sepsis, the wax gauze is removed and the graft is dressed with eusol covered with protective. The patient in a successful case is allowed up when the area is quite dry and completely epithelialised. The graft can be covered with vaseline or lanoline, and a bandage worn till the skin is strong. Most patients are loth to leave off their piece of bandage, and this is not a bad thing for it protects the graft.

COMMENTS

If one is certain that no sepsis is occurring, the dressing can be left untouched for ten days, but it is very difficult to be certain.

Case 9 was a youth who came in at a time when I was not able to skin-graft his ulcer. He was kept on a lotion of glycerin, hydrogen peroxide, and water, equal parts. This was cleaning up the ulcer to such an extent that operation was delayed. Thiersch grafts were applied to seemingly clean granulations. I left the dressing unchanged for three and a half days. On removal, the ulcer was a bed of pus, and most of the grafts had lifted off and were dead. After only another three and a half days I regrafted the ulcer with seeds and dressed it with eusol b.i.d., and in 15 days from the grafting the ulcer was completely epithelialised. Its area was 5 by 2½ in.



Two ulcers of (?) ten years' duration. Healed—right 11 days and left 15 days after grafts applied. Excision was done, but, as in later cases, more of the white scar tissue surrounding the ulcer should have been removed. Some time afterwards an acute ulcer developed in this scar tissue between the normal skin and the graft and needed excising and grafting. Healed in 17 days.

This shows: (1) the disastrous effect of an undressed ulcer where sepsis had occurred, and (2) that, to a certain extent, a graft can be made successful by eusol dressings in spite of sepsis.

Should sepsis occur beneath a Thiersch graft, the whole piece usually lifts off and a considerable area is denuded. If bleeding or serous oozing is considerable, it will lift off, if not completely, at least in places. If, in removing the graft, one goes too deeply, the area frequently takes some time to heal. In Case 57, after excision, one Thiersch graft had been applied. Of a sudden a minute fly came from "nowhere," landed momentarily on the raw area remaining, and flew away. I should have re-excised the area, but did not. The graft covering this area came off wholly, whereas the other remained firmly attached. With seeds sepsis is a much less important factor. In my first unsuccessful cases it was common to see, here and there, seeds holding (though not spreading) even when bathed in a sea of pus. Secondly, their propensity for "taking" is often extraordinary, and with enough sepsis to spoil a Thiersch graft seeds will be successful with eusol dressings. Then again, seeds can be applied where absolute hæmostasis cannot be attained. I have placed seeds around a small arteriole which persisted in bleeding. Also the area from which the seeds are removed is invariably healed in ten days. Latterly, in large ulcers, I have combined the seed and the Thiersch methods, applying the latter to dry flat areas and the former to oozing, irregular, or doubtful areas—e.g., in Cases 31, 38, 39 the graft was healed in seven, five, and seven days respectively.

I have mentioned sepsis so frequently that it may appear as though it was frequent. This is not so. In the last 45 cases, numbers 18 to 62 inclusive, it has been infrequent. My previous methods—e.g., curettage—were failures because of sepsis. And further, a great deal of my work has been done in surroundings which were anything but ideal for surgery. A leaf building with the dust and insect life which this means, and the constant spraying of insect lotions into the air to keep away intruders, keeps the word sepsis ever before one's mind. I have had one white sister most of the time, and a very raw orderly to assist her. I have done most of these ulcers with no assistant other than a native to hold the foot and the sister to keep an eye on the patient and his pulse. In a properly equipped theatre sepsis should be absent. This absence of facilities is the strongest point in my contention that this is a simple method and should produce results equal with mine in any medical man's hands.

OTHER METHODS TRIED

1. *Thorough curettage followed by seed graft.*—This was invariably followed to a greater or less extent by sepsis, which was the cause of all the non-successes. Results (8 cases): success, 1; partial success, 4; *non-success*, 3.

2. *Treatment of ulcer by dressings until clean and then skin-grafting.*—This method takes too long, and it is difficult to be sure that sepsis is absent. Results (3 cases): success, 0; partial success, 2; non-success, 1.

3. *Excision followed after a short period (three to seven days) by skin-graft.*—This is a good method, but it means two operations; the second one, however, needs only local infiltration of the skin area. Results (5 cases): success, 4; partial success, 1; non-success, 0.

SOURCES OF FAILURE

Causes of non-success were as follows:—

Case 1, sepsis.

Case 2, sepsis followed by the patient running away.

Case 9, sepsis and leaving the dressing too long before inspecting the graft.

Case 12, inefficient excision, a virulent infection in a patient of low vitality. Fatal.

Case 19, senility (aged 70) and lack of response to any treatment.

Causes of partial success.—(Partial success means that the ulcer was longer than the "minimum time" in healing.)

Cases 2, 3, 4, 8.—All were curetted and the sepsis was *not completely removed.*

Cases 10 and 11.—Time taken awaiting a clean granular surface was too long (88 and 45 days).

Cases 17 and 46.—Owing to the patient removing his bandage or taking a stroll during the night following operation grafts were dislodged. (These people are very primitive. Head-hunting has not long ceased, there is no Government official on the island, and superstition is rife. One can therefore expect such things as these accidents to happen to the grafts.)

Cases 25 and 57.—Sepsis introduced at operation (Case 25) or carried to the graft during dressings (Case 57). These are the only two cases where sepsis was of moment in the 45 cases treated as described above.

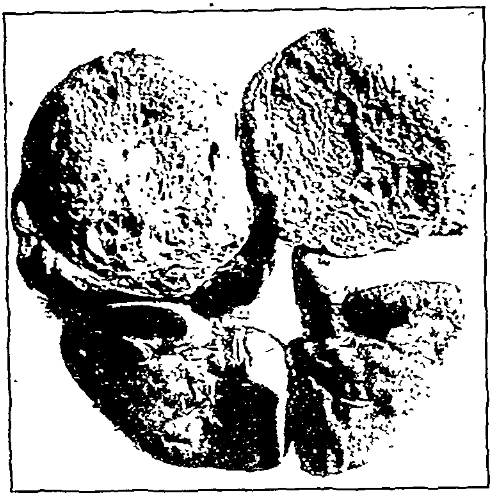
Causes of a rather longer period than usual in successful cases are to be found in delay in applying plaster to an ulcer on a malleolus or to the patient getting out of bed on the day of operation and dislodging a graft or two, 32 and 27 days respectively.

POST-MORTEM FINDINGS

A post-mortem examination was carried out, and the following is a report of the findings :—

A wasted child, with a marked waxy pallor. The eyelids are discoloured as by subcutaneous hæmorrhages.

In the *abdomen*, in the position of the left suprarenal gland, there lies a mass of irregular growth, beneath and distinct from the spleen which lies upon it, but closely adherent to the left kidney (see Figure). This mass consists of a soft but solid tumour, and is about the size of a tangerine orange. It lies upon the upper pole of the left kidney, which is flattened but not involved in the neoplasm. Surrounding the solid tumour and intimately connected with it are other smaller masses, some firm and nodular, and one definitely cystic. Over the neoplasm passes the tail of the pancreas, which is quite normal, and not involved in the tumour. The cut surface of the tumour has a honeycombed appearance, and is traversed by firm fibrous bands between which are numerous shallow and depressed areas. The right suprarenal gland is normal.



The tumour and left kidney.

No obvious secondary growths are present on the surface of the *liver*, but deep in its substance are found numerous hæmorrhagic points which are foci of malignant infection. One hæmorrhagic nodule is present which is the size of a large pea. In the lower pole of the right kidney is found one small nodule of growth—all other abdominal organs appear healthy.

In the *thorax* a few enlarged soft and fleshy glands are present in the anterior mediastinum. These enlarged glands can be traced upwards into the root of the neck, and are especially prominent behind the left sternoclavicular joint. They are also found in the bifurcation angle of the trachea. After the removal of the thoracic contents thick fleshy masses of growth are seen on the posterior wall intimately associated with the ribs beneath them. They are present on both sides of the vertebral column. Adherent to the diaphragm on the right side, and lying in close relationship with the lower lobe of the right lung, is a dark firm mass of growth which is cuneiform in shape and rather larger than a walnut. It contains a single cyst, which occupies about one-third of its bulk. In the lower lobe of the right lung is found one small nodule of growth—in all other respects the lungs are healthy. The heart and pericardium are normal.

The *brain* presents considerable œdema of the pia-arachnoid membranes, and definite pressure columns are found in the cerebellum—but in other respects it is normal, and there is no evidence of meningitis. At the base of the skull two dark swellings are found beneath the dura anteriorly. The smaller is the size of a grape, and is found in the right orbital fossa in the angle formed by the orbital plate and the vertical portion of the frontal bone. It is soft and circumscribed, and on incision exudes a quantity of thick blood. The larger swelling is diffuse and situated in front of the pituitary fossa. It extends forward and laterally over the lesser wings of the sphenoid and the orbital plates of the frontal bone, and surrounds the optic nerves. The same thick bloody fluid exudes from this as from the smaller swelling; there is little or no firm tissue present. A slight circumscribed discoloration on the anterior aspect of the frontal bone above the left supra-orbital ridge suggests the commencement here of another metastasis. Histologically the suprarenal tumour and its metastases were found composed of small, round, closely packed and deeply staining cells. The appearances in sections are typical of a neuroblastoma of the suprarenal gland.

COMMENT

It will be seen, from a consideration of this case, that the distribution of the secondary deposits was by no means typical—for instance, none was found in the lumbar glands, and there was evidence of only one in the cranial bones. The subdural deposits are very unusual; though the case presented the common symptom of blindness, this came about in an entirely unusual, and hitherto unrecorded, manner, and there was never any proptosis, papillœdema, or optic atrophy such as is almost invariably described in these cases. Diagnosis was extremely difficult and was never definitely made; at one time that of leukæmia was considered, though no fundus change of any kind was ever present. The secondary anæmia was typical; but there was also a definite lymphocytosis which has not been remarked before. Again, no explanation is forthcoming as to the nature of the subcutaneous nodules; it is possible that these were really atypical secondary deposits of which the cellular elements had degenerated.

NOTES UPON HYPNOTIC STATES

BY ALEXANDER CANNON, M.D. LEEDS, PH.D., D.P.M.

I HAVE formed the following conclusions as a result of some years of work on normal and abnormal subjects in the hypnotic states.

(I.) The field of consciousness is narrowed during hypnosis, as is evidenced in the person hypnotised adding up figures.

(*a*) The subject is commanded to open his eyes without awakening, whilst a paper is placed before him containing two or more columns of figures, one column of which he is told he can see (a negative hallucination is suggested for the others). The visualist sees the letters either become smaller and smaller, indistinct, more faint, or appear farther away, as he carries out the process of addition. On the other hand, the auditory thinker can detect no change in the figures—as a rule he says that he did not take notice—but when the numbers to be added up are (*b*) dictated to him, with his eyes closed, he believes that the hypnotist's voice gets softer and softer, or more and more indistinct, until towards the end he can hardly hear the numbers being called out. (*c*) The visuo-auditory thinker detects slighter growth was carcinomatous rather than sarcomatous in nature, in spite of its appearance, and that the clinical picture differed radically according as to whether the growth occurred on the right side or on the left. His paper is of sufficient importance to warrant a summary of his argument.

In reviewing the subject in general he gives the age-incidence as from 2 weeks to 10 years, the majority of cases occurring between the ages of 2 and 3 years. Heredity and trauma may be discounted as factors in its occurrence; 51 of his cases were left-sided and 22 right-sided. In all cases where the blood was examined he reports a marked secondary anæmia.

When the growth occurs on the left side, evidences of spread and secondary deposits are commonly found in the lumbar glands and those in relation to the aorta and the common iliac arteries. A common feature of such cases is pain in the lower limbs, which Frew attributes to pressure on the lumbar plexus by the enlarged glands. The other glands affected are the intercostal, mesenteric, those at the hilum of the liver and in the posterior mediastinum, a knot behind the inner end of the left clavicle, and the anterior deep cervical. The bony secondary deposits are located in the ribs, sternum, maxillæ, and cranium in the medullary cavities; exophthalmos commonly occurs on the side where the cervical glands are the largest, and in a left-sided growth this is usually on the left side.

In right-sided cases there is a tendency for the growths to be larger, to involve the kidney, and often to remain localised to the abdomen. The glands more usually involved are those on the upper surface of the liver and diaphragm, the anterior mediastinal, and those at the inner end of the right clavicle; the lungs and lung roots are commonly the seat of secondary deposits. Proptosis usually occurs first on the ipsolateral side, and there is no pain in the limbs; the growth is usually palpable and, as in left-sided cases, there is marked secondary anæmia.

From the anatomical fact that the lymphatics from the left suprarenal gland run to the lumbar glands, whereas those from the right run to the right lymphatic trunk, Frew concludes that spread of the neoplasm occurs via the lymphatics, and that anatomical considerations will explain the two different clinical types. He also concludes that the growth is carcinomatous in nature—which is reasonable, when it is considered that it arises from a tissue originating in the neural ectoderm.

As to frequency of occurrence of this disease, it is felt that the adjective rare is justified; one cannot but feel that the long lists of cases given by some of the earlier writers must include diseases other than the one under consideration. In the Paddington Green Children's Hospital some 40 post-mortem examinations are made in a year, and the annual turnover of in-patient cases is in the neighbourhood of 800; during the last 20 years, as nearly as I am able to ascertain, there have come under observation four cases of the disease, of which three were confirmed post mortem. Dr. Reginald Lightwood has kindly provided me with similar figures from the Great Ormond-street Children's Hospital; with an annual turnover of some 7000, with 200 post-mortem examinations in the year, there have been seen six cases of adrenal neuroblastoma in the last six years, of which five were confirmed post mortem. In his investigations Frew found that in 7000 consecutive autopsies on children under 12, 25 cases were reported. Considered as a percentage occurrence at post-mortem examinations, the figures from these three different sources are, therefore, 0·38, 0·42, and 0·36 per cent. respectively.

RECORD OF A CASE

My interest in the condition was aroused by my having to deal with the case here described; while showing some typical features, it was so atypical in many ways that it is worthy of record.

A male child, 11 months of age, was brought to me on *June 20th, 1931*, by his mother, who complained that, in her opinion, the child had been blind for a week; apart from some unusual irritability, she had noticed no other change in the child. The patient was a third child, the previous two, both prematurely born, having died at the age of 6 weeks and 11 weeks respectively from causes unconnected with this patient's condition.

On examination in the out-patient department of Paddington Green Children's Hospital it was found that there was no response whatever on the child's part to any kind of visual stimulus. The pupils were perhaps a little dilated and quite inactive; there was slight head retraction and a faint rash over the back and chest, but no other positive sign. In spite of the inactivity of the pupils, a tentative diagnosis of cortical amaurosis from post-basic meningitis was made, and the child admitted into hospital. The temperature was 98·8° F., pulse-rate 156, and respirations 24. The tongue was furred, and the tonsils and submaxillary glands enlarged. Nothing abnormal was found on examination of the thorax; there was slight abdominal distension, and several subcutaneous nodules were palpable, situated as follows: one over the eleventh rib in the scapular line; one, with satellites, in the left iliac region; one in the left lumbar, and one in the right iliac regions. These lumps were all hard in consistency, and measured roughly 1 by 1 in., their edges were irregular, and they were free of the skin though attached to deep structures.

In the left hypochondrium there was palpable a tender abdominal tumour, the size of an orange, with an irregular rather sharp edge; the tumour moved downwards and inwards on respiration, its dullness was continuous with that of the spleen, and it was regarded by all observers as being an enlarged spleen. The liver was of normal size; motor and sensory power (apart from vision) were normal, and all reflexes (apart from the pupillary reflex) were normal.

One of the subcutaneous nodules was excised; microscopical examination revealed the fact that it consisted merely of poorly vascularised fibrous tissue.

The blood count was as follows:—

Red cells	*3,210,000*	*Polymorph*	27·6%
White cells	12,500	Lymphocytes	69·2%
Poikilocytes ..	Many	Hyal. transitional ..	2·8%
Nucl. red cells ..	95%	Eosinophils	0·4%
Hæmoglobin ..	40%	Basophils	Nil
Colour-index ..	0·62		

Polychromasia was present.

The cerebro-spinal fluid was slightly turbid with one drop of blood. Cell count, 10 per c.mm. The slight excess can be explained by the small amount of blood present. No organisms were found in films; no pathogenic organisms were present in culture.

One of the most important points about the case is that, throughout the whole illness, there was never any proptosis, papillœdema, or other ocular manifestation, with the single exception of the absent pupillary reflex already mentioned.

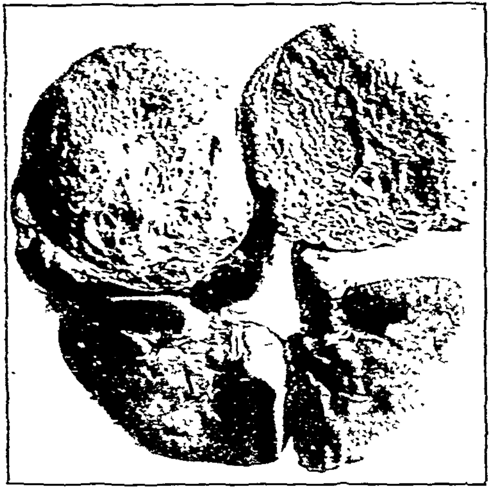
Generally speaking, the child was restless and fretful, frequently perspiring about the face and head, and showing a slight but definite degree of head retraction. The temperature and pulse-rate varied *considerably, reaching* 101·2° and 180 respectively on the 23rd and 24th, 103·8° and 156 on the 28th, 104·4° and 180 on the morning of July 6th, and falling to 98·4° and 140 on the 3rd. The bowels were regular; vomiting occurred on June 21st, 22nd, July *5th* and 6th. Loss of weight began to be evident on the 4th, when the skin became very pale, wrinkled, and inelastic; sedatives were necessary at times from this date onwards. At this time there appeared a blood-stain in the *right lower eyelid* which became progressively larger and darker, a similar stain appearing on the left lower lid shortly before death. A second lumbar puncture was performed on the 5th, and fluid under considerable pressure was withdrawn; this was not the case when the first specimen was taken, no increase of pressure being detected then. Early on the 7th the pulse was impalpable, and respirations rapid and gasping; death occurred at 6 A.M.

POST-MORTEM FINDINGS

A post-mortem examination was carried out, and the following is a report of the findings:—

A wasted child with a marked waxy pallor. The eyelids are discoloured as by subcutaneous hæmorrhages.

In the *abdomen*, in the position of the left suprarenal gland, there lies a mass of irregular growth, beneath and distinct from the spleen which lies upon it, but closely adherent to the left kidney (see Figure). This mass consists of a soft but solid tumour, and is about the size of a tangerine orange. It lies upon the upper pole of the left kidney, which is flattened but not involved in the neoplasm. Surrounding the solid tumour and intimately connected with it are other smaller masses, some firm and nodular, and one definitely cystic. Over the neoplasm passes the tail of the pancreas, which is quite normal and not involved in the tumour. The cut surface of the tumour has a honeycombed appearance, and is traversed by firm fibrous bands between which are numerous shallow and depressed areas. The right suprarenal gland is normal.



The tumour and left kidney.

No obvious secondary growths are present on the surface of the *liver*, but deep in its substance are found numerous hæmorrhagic points which are foci of malignant infection. One hæmorrhagic nodule is present which is the size of a large pea. In the lower pole of the right kidney is found one small nodule of growth—all other abdominal organs appear healthy.

In the *thorax* a few enlarged soft and fleshy glands are present in the anterior mediastinum. These enlarged glands can be traced upwards into the root of the neck, and are especially prominent behind the left sternoclavicular joint. They are also found in the bifurcation angle of the trachea. After the removal of the thoracic contents thick fleshy masses of growth are seen on the posterior wall intimately associated with the ribs beneath them. They are present on both sides of the vertebral column. Adherent to the diaphragm on the right side, and lying in close relationship with the lower lobe of the right lung, is a dark firm mass of growth which is cuneiform in shape and rather larger than a walnut. It contains a single cyst, which occupies about one-third of its bulk. In the lower lobe of the right lung is found one small nodule of growth—in all other respects the lungs are healthy. The heart and pericardium are normal.

The *brain* presents considerable œdema of the pia-arachnoid membranes, and definite pressure columns are found in the cerebellum—but in other respects it is normal, and there is no evidence of meningitis. At the base of the skull two dark swellings are found beneath the dura anteriorly. The smaller is the size of a grape, and is found in the right orbital fossa in the angle formed by the orbital plate and the vertical portion of the frontal bone. It is soft and circumscribed, and on incision exudes a quantity of thick blood. The larger swelling is diffuse and situated in front of the pituitary fossa. It extends forward and laterally over the lesser wings of the sphenoid and the orbital plates of the frontal bone, and surrounds the optic nerves. The same thick bloody fluid exudes from this as from the smaller swelling: there is little or no firm tissue present. A slight circumscribed discoloration on the anterior aspect of the frontal bone above the left supra-orbital ridge suggests the commencement here of another metastasis. Histologically the suprarenal tumour and its metastases were found composed of small, round, closely packed and deeply staining cells. The appearances in sections are typical of a neuroblastoma of the suprarenal gland.

COMMENT

It will be seen, from a consideration of this case, that the distribution of the secondary deposits was by no means typical—for instance, none was found in the lumbar glands, and there was evidence of only one in the cranial bones. The subdural deposits are very unusual; though the case presented the common symptom of blindness, this came about in an entirely unusual, and hitherto unrecorded, manner, and there was never any proptosis, papillœdema, or optic atrophy such as is almost invariably described in these cases. Diagnosis was extremely difficult and was never definitely made; at one time that of leukæmia was considered, though no fundus change of any kind was ever present. The secondary anæmia was typical; but there was also a definite lymphocytosis which has not been remarked before. Again, no explanation is forthcoming as to the nature of the subcutaneous nodules; it is possible that these were really atypical secondary deposits of which the cellular elements had degenerated.

NOTES UPON HYPNOTIC STATES

BY ALEXANDER CANNON, *M.D. LEEDS, PH.D., D.P.M.*

I HAVE formed the following conclusions as a result of some years of work on normal and abnormal subjects in the hypnotic states.

(I.) The field of consciousness is narrowed during hypnosis, as is evidenced in the person hypnotised adding up figures.

(*a*) The subject is commanded to open his eyes without awakening, whilst a paper is placed before him containing two or more columns of figures, one column of which he is told he can see (a negative hallucination is suggested for the others). The visualist sees the letters either become smaller and smaller, indistinct, more faint, or appear farther away, as he carries out the process of addition. On the other hand, the auditory thinker can detect no change in the figures—as a rule he says that he did not take notice—but when the numbers to be added up are (*b*) dictated to him, with his eyes closed, he believes that the hypnotist's voice gets softer and softer, or more and more indistinct, until towards the end he can hardly hear the numbers being called out. (*c*) The visuo-auditory thinker detects slighter changes in both the visual and auditory tests, but the visual test is the most marked. (*d*) The kinæsthetic thinker (thinks in movements) finds the effort of lip and other movements becoming more and more difficult as he continues to add up the column of figures.

I consider that these phenomena are due to the limitation of the field of consciousness in the hypnotic state, which may be explained as follows. If ten-tenths is the limited field of consciousness, when two-tenths is occupied with addition, there only remains eight-tenths for vision or audition, and as the addition proceeds and takes up more and more room in this limited field of consciousness, by the time eight-tenths of consciousness is occupied with addition, there only remains two-tenths for vision or audition, and therefore the sight or hearing is greatly reduced in power. The same applies to movement.

(II.) The most mentally alert thinker thinks in pictures, but as fatigue sets in he begins to think in terms of hearing, and later in terms of movement. In the limited hypnotic conscious state this is easily demonstrated. The subject is told to dream that he is a bank clerk adding up column after column of figures, of two or three figures in a row, and that he can either look through the columns of the figures in the book as he adds up, or he can listen to the (imaginary) person standing by him, who will also be calling out the figures, or that he can say them to himself to assist him in adding up. The actual figures are dictated. The results which are remarkably constant show that the person first sees the columns in the book, but as the calculations continue he begins to cease to see the columns of figures, but now hears the person nearby calling them out to him, and later ceases to hear him say them, so now has to resort to "say" them to himself. I call this the fatigue phenomenon, the types of thought running from visual to auditory, and then to kinæsthetic as the effort becomes greater.

(III.) The lower the intellectual standard of a person the greater is his difficulty in visualising during the hypnotic state; he often cannot visualise at all, and his mind becomes a "blank," although in the waking state he can visualise, he may not be able to imagine sound unless he can first visualise what produces the sound. In this type of person it is observed that the chest movements are greatly diminished during the hypnotic state.

RESPONSES IN MENTAL DISORDER

(IV.) A "complex" can be determined by the person refusing to accept the suggestion of the particular thing mentioned, such as the word river in one who contemplates or has attempted suicide. On cross-examination afterwards, which is the subjective method used for all the tests, the person does not remember dreaming of a river in this case, or only remembers after great effort and then with hesitation. Emotional reactions can likewise be noted.

(V.) During the waking state stammerers are mainly auditory thinkers, but during hypnosis they are visual thinkers, as determined by subjective cross-examination after hypnosis. The patients can easily picture a thing during the hypnotic state, but during the waking state they audit or hear sounds but do not pay much attention to visualisation. This suggests the reason for so many "cures" of stammering by "periods of silence" and the like, when the thought must become visual. It is common knowledge in alienistic circles that when a stammerer is in the hypnotic state he ceases to stammer.

(VI.) The manic-depressive or cycloid or extrovert types of mental make-up can easily be distinguished from the dementia præcox, or schizoid or introvert types, by noting their reaction to hypnosis, the extroverts never going quite so deep as the introverts, although often more easily hypnotised, and, vice versa, the introverts going deeper than the extroverts, although much more difficult to hypnotise at first. Further, the subjective examination also shows that the extroverts are more of the auditory type of thinkers, and the introverts are more of the visual type.

MEMORY, AUTO-HYPNOSIS, AND SLEEP

(VII.) There are three types of person as regards memory for what happened during the hypnotic state:—

1. He who remembers nothing whatsoever of the events during hypnosis, and has to be re-hypnotised in order to be cross-examined as to his subjective reactions.
2. He who remembers fragments of his dreams dictated and whose memory has to be assisted, perhaps even by re-hypnosis, for the isolated events.
3. He who remembers everything of what took place during hypnosis regarding the dictated thoughts, and does or does not have any recollection of outside events during this period, and certainly could not open his eyes, even when told to try to do so, after the suggestion has been made that he cannot.

(VIII.) It would appear that hypnosis is a dissociated state in which the higher centres are certainly more fully alert and the lower centres more asleep (Mr. A is awake, and Mr. B is asleep).

(IX.) An extensor plantar response (Babinski) is often obtained both in deep sleep and certainly in the fifth and sixth stages of Liébeault (the deep hypnosis where complete amnesia remains for the hypnosis), which in both cases is due to profound *inhibition of certain cortical functions*.

(X.) Gower's case of "half-waking somnambulism" might quite possibly have been one of auto-hypnosis of the third degree of Liébeault (the subject is also conscious of everything going on around him to a certain extent, and hears every word addressed to him, but he is oppressed by great sleepiness. An action communicated to a limb is automatically continued. If the arm is rotated to begin with, it goes on rotating until the operator directs its stoppage). The only two cases I have seen of narcolepsy strongly suggested a spontaneous self-hypnosis of the third degree, apart from being considered by some authorities as an "epileptic equivalent."

(XI.) It has been shown that sleep can occur without loss of consciousness, and loss of consciousness can occur without sleep. Is hypnosis then a particular and peculiar form of sleep? Fatigue is not necessary for either sleep or hypnosis. Fatigue might actually prevent sleep. Pavlov's theory would explain sleep and hypnosis as varieties of cortical inhibition. He states that the cortical elements are functionally exhausted with comparative ease, and speaks of a "*scattered sleep*" or sleep of separate groups of cellular structures. R. D. Gillespie refers to Richardson's drowsy subject in which greater mental effort actually sends the subject to sleep.

STAGES OF HYPNOSIS

(XII.) I still consider that Liébeault's classification is the best:—

Stage 1.—The patient feels a heaviness of the eyelids and a general drowsiness.

Stage 2.—Characterised by suggestive catalepsy. When the hypnotist places the arm in a certain position and says that it is to remain there, it is impossible for the patient to pull it down. The arm remains rigid and fixed for a much longer time than would be possible in the natural state. In the first and second degrees or stages, consciousness remains almost complete. and often the patient denies having been in the hypnotic state because he has heard and remembers every word which has been spoken to him. (A very large proportion of people never pass beyond this stage.

Stage 3.—The subject is also conscious of everything going on around him to a certain extent, and hears every word addressed to him. but he is oppressed by great sleepiness. An action communicated to a limb is automatically continued. If the arm is rotated to begin with. it goes on rotating until the operator directs its stoppage.

Stage 4.—The patient ceases to be in relation with the outer world. He hears only what is said to him by the hypnotist.

Stage 5.—Stage of somnambulism. when what has occurred during sleep is indistinct and recalled with difficulty.

Stage 6.—Stage of somnambulism. when the patient is unable to recall spontaneously anything which has occurred while asleep. All the phenomena of post-hypnotic suggestion can be induced in this stage.

Hypnotism is the production of a psychical condition in which the faculty of receiving impressions by suggestion and the power to act upon and carry out the suggestions made is greatly increased.

(I hope shortly to publish. with others. physiological records of some of these hypnotic states.)

London.

THREE FATAL CASES OF

PULMONARY EMBOLISM IN RELATION TO PREGNANCY

By John Beattie, F.R.C.S.Eng., M.C.O.G.

RESIDENT ASSISTANT PHYSICIAN ACCOUCHEUR,
ST. BARTHOLOMEW'S HOSPITAL

Sudden death without symptoms is rare in pregnancy, labour. or the puerperium; the cause is most often found to be a massive embolus obstructing one or both pulmonary arteries, with consequent asphyxia and heart failure. Because of the comparative rarity of this condition it is thought justifiable to publish a description of three cases which have been observed in St. Bartholomew's Hospital during the last ten years, out of a total of 3500 consecutive pregnancies which were cared for in the maternity department of the hospital during this period. The incidence at this hospital is therefore 0·08 per cent., but the figures are too small to be of much practical value. In other publications on this subject the incidence is given as 0·06 per cent. in 190.000 collected cases of pregnancy, but this figure is not constant. for Richter [1] gives the incidence as 0·12 per cent. in 16,000, and Devraigne [2] as 0·04 per cent. in 45,000 pregnancies.

Pulmonary embolism is extremely rare during pregnancy and in labour; the majority of cases which it complicates have reached the puerperium. Bunzel [3] in 32 cases found that 24 developed embolism in the puerperium, 6 in the first few months of pregnancy. and only 2 during labour. Of the three cases here described one was at the seventh month of pregnancy. one in the second stage of labour. and one on the seventeenth day of the puerperium.

Embolism may complicate pregnancy at any age in the childbearing period of life. but the incidence appears to be twice as high in primiparæ as in multiparæ, probably because operative interference in the delivery of the fœtus is. to a small extent, a predisposing factor. Bunzel and others have stated that pulmonary embolism, quite apart from air embolism, has been recorded in a comparatively high percentage of cases of Cæsarean section and after delivery with placenta prævia. In the puerperium embolism may take place at any time, but from a study of many published cases it seems to be most prevalent between the fifth and twelfth days.

The great veins of the lower extremities, especially the great saphenous vein and the deep femoral or common femoral veins, are the most common situations in which the thrombus is found. Only rarely is the primary thrombus found above the inguinal ligament. but a few cases have been reported in which the external iliac vein and the hypogastric vein were primarily involved (Laennec).[2] The last case here described, in which death occurred on the seventeenth day of the puerperium, was found to have a large thrombus in the left hypogastric vein from which the embolus had arisen, but this is a most unusual site; such a thrombosis would probably commence at the placental site, and must first spread through the tortuous and comparatively small veins of the uterine plexus before reaching the hypogastric or ovarian vessels. and it is only from the latter that a large thrombus could separate and produce a massive pulmonary embolism. One is quite familiar with cases in which showers of small infected emboli produce lung infarcts in cases of puerperal endometritis. but in such cases massive embolism is very rarely seen, and they appear to have quite a different ætiology from those of massive pulmonary embolism, for the primary focus of the thrombosis in the latter cases rarely shows evidence of an acute infective process.

PREDISPOSING FACTORS

The predisposing factors of pulmonary embolism when related to pregnancy are difficult to define. It is unlikely that the inguinal ligament plays any part in the process by its pressure upon the common femoral vein. Possibly ante-partum and post-partum hæmorrhage and reduced cardiac force predispose to it, but a study of the cases hitherto published does not produce evidence in favour of such a supposition. The three cases described in this contribution were all normal in this respect. and there is no evidence that any of them were suffering from a degree of anæmia.

Aschoff [4] has stated that the thrombosis is caused primarily by changes in the blood plasma. the elements of the blood and its rate of flow. the first step being a local collection of platelets along the vessel wall following a widening of its lumen and damage to the endothelial lining secondary to mechanical factors, and increase of the venous pulse, which tends to slow the blood stream in this area. This first step is followed by the deposition of further blood platelets until the flow of blood ceases altogether. and in this situation a white infarct is formed. It is from the red infarct which forms on the proximal side of the latter that the embolus separates. Aschoff describes a case in which the pulmonary embolus exactly fitted the femoral vein in which the primary thrombus arose. In one of the cases here described the pulmonary embolus showed a mark upon it, which corresponded to a valve in the femoral vein from which it had separated. Von Recklinghausen considered that abnormal eddies in the venous blood stream were a more important factor in the production of thrombosis and embolism than the actual mechanical slowing of the blood stream.

The incidence of pulmonary embolism in pregnancy is very low, and it is improbable that the presence of the pregnant uterus plays any particular part in the production of this complication, for the cases described in the literature do not appear to take place essentially in the patient who has severe varicose veins or even œdema due to pressure from mechanical factors.

The signs and symptoms of massive pulmonary embolism are well known ; there is often sudden pain, either in the præcordial region or posterior aspect of the chest, with cyanosis, dyspnœa, air-hunger, a raised pulse-rate of the "climbing" variety (Mahler's sign), and possibly also a cough and blood-stained sputum if death is delayed. In most cases there are one or two of these signs and symptoms. When death is immediate the patient either sits up suddenly or falls down dead with no previous symptoms except perhaps a gasping sigh.

TREATMENT

Treatment of those cases in which the embolus is lodged in the main branches of one or both pulmonary arteries is usually of no avail, and amounts to the administration of cardiac stimulants and the inhalation of amyl nitrite and oxygen. It seems practically impossible to discover during pregnancy the patients who are peculiarly liable to suffer from embolism either before or after the delivery of the child. Theoretically, treatment should be directed particularly towards women who are anæmic, by the administration of iron and arsenic and possibly by blood transfusion, especially in cases of ante-partum or post-partum hæmorrhage.

Some observers advise that for anæmic patients the foot of the bed should be kept permanently raised during the puerperium, and even that the legs should be bandaged from the ankle upwards with a spiral crêpe bandage, but the prophylactic value of such a procedure is certainly doubtful, and it is unjustifiable as a routine treatment.

Of the three cases described in this contribution, in one death followed a severe fall at the seventh month of pregnancy with the subsequent application of a plaster spica to one thigh. In the second case death occurred during the second stage of labour; antenatally, the patient had complained of a little pain over the site of the right deep femoral vein, and it was from this region that the embolus arose. Possibly, if this patient had been confined to bed for the last three months of her pregnancy the catastrophe might have been averted, but even this is doubtful. The last case described was one in which death occurred on the eighteenth day of an apparently quite normal puerperium, and there was nothing to indicate that there was any massive thrombosis in the pelvis while she was still an in-patient at the hospital, but post mortem a large breaking-down thrombus was found in the left hypogastric vein, and the placental site showed evidence of infection. The embolus apparently arose from the left hypogastric vein.

THREE CASE RECORDS.

CASE 1.—A woman, aged 28, was admitted to St. Bartholomew's Hospital in July, 1922. She had had two quite normal pregnancies, the last child being born in 1916. She was seven months' pregnant, and 14 days previously she had slipped and fallen heavily on her left side. She lost consciousness for half an hour, and afterwards walked up to the hospital, where she had the left femur radiographed. The appearances of the plate suggested that there was a flake of bone separated from the edge of the acetabulum, and she was therefore put up in a plaster spica, with the plaster in relation to the anterior abdominal wall well cut away to allow room for the pregnant uterus. Twelve days later, while at stool, she suddenly lost consciousness and became breathless and cyanosed, but without pain, cough, or sputum. Twelve hours later she was transferred to St. Bartholomew's, and she died 24 hours after admission.

On admission the patient was very cyanotic and breathless; the pulse-rate ranged from 110–130, but the pulse was hardly perceptible at the wrist. The heart sounds were feeble, but no enlargement was detected. The lungs were emphysematous with no added sounds, and no evidence of œdema at the bases. The blood count was quite normal. The urine contained a trace of albumin but was otherwise natural. On post-mortem examination two ante-mortem clots were discovered, the largest, 2½ in. long, in the left pulmonary artery, and the other one, 2 in. long, completely blocking the right pulmonary artery; one clot showed the mark of the vein in which it had formed. The left acetabulum was normal, but there was a partial subluxation of the left sacro-iliac joint with hæmorrhage between the joint surfaces. The pelvic veins were normal, and so also were the uterus and placental site.

A large ante-mortem clot was present in the common femoral vein of the left side, commencing at its junction with the profunda femoris and extending up to the common iliac vein of the same side, involving also the internal iliac vein.

CASE 2.—A woman, aged 30, was admitted to St. Bartholomew's Hospital for the delivery of her second child at full term in December, 1931. At the time of admission she was not in labour. She had had one previous pregnancy in 1927, and had had forceps delivery of a normal vertex presentation with no complication in the puerperium. Since April, 1928, she had been treated in the orthopædic department for spondylitis deformans, the whole spine being rigid, *with a marked kyphosis from the cervical region* to the second lumbar vertebra. The chest expansion was very limited.

During her second pregnancy she had first been seen eight weeks after the cessation of menstruation and again regularly each month. It was not until the seventh month that she complained of a tender area situated high up on the anterior surface of the right thigh, and in this region a small tender indurated plaque was palpable, and at the same time a little œdema around the right anke-joint was discovered. This condition improved during the next two months, and no treatment was adopted at the time. Throughout pregnancy the patient complained of dull pain in the spine, but she had suffered from this symptom since the onset of the spondylitis deformans in 1928. At term the presentation was a vertex with the fœtal head well engaged in the true pelvis; when admitted to hospital there was a little œdema around the right ankle-joint. The left leg was normal.

This patient went into labour and the first stage lasted seven hours. After two and a half hours she suddenly became breathless and slightly cyanosed, and the pulse-rate rose from 90 to 104 beats per minute. Otherwise there were no abnormal symptoms; she was not anxious or in any pain, and her mentality was quite normal. This condition lasted throughout the rest of the first stage of labour, and not until the fœtal head was actually on the perineum did she quietly die. Half an hour before death her pulse-rate rose rapidly until it became uncountable, but respiration was not greatly laboured; there was a considerable degree of cyanosis of the lips and cheeks.

The post-mortem findings were as follows: A large ante-mortem clot filled both pulmonary arteries; the lungs were extremely congested, and there was no evidence that *the embolism had occurred in two* or more stages; the clot filling the pulmonary arteries showed the mark of a valve from the vein in which it had first formed. The primary site of the thrombus was found to be in a branch of the profunda femoris vein of the right side, and from this region the clot had spread into the common femoral vein, completely filling its lumen. The placental site, uterine and ovarian veins were quite normal. The other organs of the body were normal on examination. The spinal column showed no gross anatomical changes.

CASE 3.—A woman, aged 34, was admitted to St. Bartholomew's Hospital in October, 1930, for delivery of her third child. She had had two previous pregnancies, both normal except for a small external, accidental hæmorrhage during the first. At the third pregnancy she was delivered of twins, both vertices, and had an uneventful labour and puerperium until discharge from hospital on the twelfth day. She showed no abnormal rise of pulse-rate or temperature during her stay in the hospital, nor was there any other evidence of an endometritis. On the seventeenth day after delivery she was walking in the street when she suddenly collapsed, and was immediately brought by ambulance to the hospital, where she died in a few minutes. At the time of admission she was greatly cyanosed and breathless, with uncountable pulse.

The post-mortem findings were: some hypertrophy of the left ventricle of the heart and thickening of the tricuspid valves, with a large ante-mortem clot in both main branches of the pulmonary arteries, completely occluding them. Both lungs were greatly congested, and there was some mucopus in the lesser bronchi. The great veins of the lower extremities were quite normal. The placental site showed evidence of an infection. The uterus itself was bulky and soft, and there was a small piece of adherent placenta at the fundus. In the left uterine and hypogastric vein was a large breaking-down thrombus, and there was a small ante-mortem clot in the radicle of the left ovarian vein. The embolus had arisen from the left hypogastric vein.

Clinical and Laboratory Notes

RUPTURED COLON SACCULUS IN SISTERS

By R. J. Willan, M.V.O., F.R.C.S. Eng., K.H.S.

HONORARY SURGEON TO THE ROYAL VICTORIA INFIRMARY, NEWCASTLE-ON-TYNE; LECTURER IN SURGERY, UNIVERSITY OF DURHAM COLLEGE OF MEDICINE

Rupture of a colon sacculus in two closely related members of the same family is rare. I cannot claim to have made any exhaustive search, but a limited inquiry fails to disclose another record of it.

The cases recorded below are those of two sisters, and they were both aged 54 at the time of the happening. In each instance the affected portion of the intestine was the pelvic colon, while the symptoms and signs simulated perforation of the vermiform appendix with transposition of the viscera. In neither case could further sacculi be found. Both patients made an uninterrupted recovery, although the elder sister had a perforated vermiform appendix with abscess 15 months later, for which I successfully operated.

Case 1.—Miss M. F., aged 54, on Dec. 27th, 1927, complained of pain in the right side of the abdomen. The pain did not become really acute until two days later when she sent for her doctor. On the following day the symptoms became more pronounced and Dr. T. W. Hay, of Newcastle-on-Tyne, invited me to see her. I first examined her at 4 P.M. on Dec. 30th, when the physical signs were those of a perforated appendix, situated in the pelvis in a patient with *transposition* of the viscera—*i.e.*, there was marked rigidity and tenderness in the hypogastrium more pronounced in the left side. Her temperature was 100·6 °F., while the pulse-rate was 110 per minute. The heart and liver were in their *normal situations.* A white cell blood count showed a well-marked *leucocytosis.* She was removed to a private hospital and operated on at 10 P.M. the same day, through a muscle-cutting incision over the left iliac fossa. A ruptured sacculus at the middle of the pelvic colon was found, with a stercolith ¾ in. × ¼ in. lying free on the pelvic floor; there was accompanying pelvic peritonitis with no attempt at localisation of the mischief. The perforation was closed with interrupted catgut sutures and the closure reinforced by anchoring adjacent appendices epiploicæ over the site. The area was drained and she made an uneventful recovery. No other saccules could be found.

In March, 1929, she was readmitted with a perforated appendix with abscess. The appendix was removed and the abscess drained. She made a good recovery.

Case 2.—Miss D. F., aged 54 (sister of the above), was seized with pain in the left side of the abdomen on March 1st, 1932. The pain was not acute at first, but a tender swelling appeared in the left flank. For three months previous to this she states that she could not bear any pressure on the left side of her abdomen, but thought it had something to do with her chronic spinal condition. She has worn a splint for immobilisation of the vertebral column for some years. I saw her in consultation with Dr. Hay that night. She then had a rounded swelling the size of a hen's egg, in the left side of the abdomen, at the level of the outer side of the middle of the descending colon. There was no rigidity of the overlying muscles. Her temperature was 102·6° F. There had been no vomiting.

She was removed to a private hospital for observation. Her urine was normal chemically and microscopically. A barium enema was employed as an aid to diagnosis but a normal radiogram was obtained. In the first 48 hours after admission the pain gradually increased in severity, coming on in spasms and the swelling became more tender. There was still no muscle-guarding and the temperature persisted at the same level. Except for the absence of vomiting, the signs and symptoms were very suggestive of acute appendicitis occurring on the left side. The viscera, however, were not transposed.

On the evening of March 3rd the pain became suddenly more pronounced, and for the first time rigidity appeared over the swelling. Immediate operation was decided upon. At the operation two loops of a very long pelvic portion of the colon were found bound together by recent adhesions enclosing a small collection of thick offensive pus. In the midst of these adhesions there was a perforated sacculus of the colon. A small hard stercolith lay loose in the cavity. The pus and stercolith being removed, the perforation was closed by interrupted sutures of catgut and an india-rubber tissue drain was placed near the site. There was no evidence of any further sacculi. Recovery was uneventful.

Both patients are now well and free from all abdominal symptoms.

NOTE ON A STABLE SUSPENSION OF DIBENZANTHRACENE IN WATER

By I. Berenblum, M.D., B.Sc. Leeds

RILEY-SMITH RESEARCH FELLOW, DEPARTMENT OF EXPERIMENTAL PATHOLOGY AND CANCER RESEARCH, UNIVERSITY OF LEEDS

In 1930 Kennaway[1] and Hieger[2] discovered that a pure aromatic hydrocarbon—1:2:5:6-dibenzanthracene—is capable of producing epithelial tumours in mice when a solution in benzene is applied repeatedly to the skin. An investigation into the action of this substance when injected into the animal body is a natural sequence. This method would permit the study of tumour induction at the site of injection in different regions of the body, and could further be used in attempting to sensitise the animal as a whole to the carcinogenic action of non-specific irritants.

At first, suspensions of dibenzanthracene in lard, olive oil, and other fatty media were tested subcutaneously in mice and rats (Burrows, Hieger, and Kennaway[3]), resulting in the development of spindle-cell sarcomata at the site of injection. More recently Burrows[4] was able to produce similar tumours in rats by repeated intraperitoneal injections of a solution of dibenzanthracene in olive oil emulsified in 5 per cent. gum acacia.

Unfortunately, the use of fats in the preparation of these mixtures, especially when heat is necessary to facilitate solution, introduces the possibility of certain fallacies, which have been discussed in the communications mentioned above. Further difficulties arise if the intravenous method of injection is contemplated. All these difficulties could be overcome, however, if a colloidal solution of dibenzanthracene in water could be prepared.

I have devised a method of preparing a stable suspension which should answer the purpose, using white crystalline 1:2:5:6-dibenzanthracene, purified by the method described by Cook.[5] 10 c.cm. of a 0·1 per cent. solution of this compound in pyridine is added drop by drop from a burette to 90 c.cm. of distilled water, the mixture being stirred throughout the process. The opalescent solution, thus produced, is then poured into collodion sacs and dialysed against water for two or three days until all the pyridine has been removed. If carefully prepared, a relatively stable colloidal solution is obtained, which may be boiled for a short time with safety. It tends to precipitate when saline is added, but is fairly stable in the presence of serum. It can be prepared in a more concentrated form by slowly adding 20 c.cm. of a 0·2 per cent. solution of dibenzanthracene in pyridine to 80 c.cm. of a 6 per cent. solution of gum acacia, and then dialysing for several days against water. This produces a stable suspension, four times the concentration of that prepared by the first method, and is probably the more suitable for injection experiments.

I have pleasure in recording my indebtedness to Dr. A. Wormall for his valuable suggestions.

COLLOIDAL SOLUTIONS OF 1 : 2 : 5 : 6-DIBENZANTHRACENE

By E. Boyland, Ph.D.

PHYSIOLOGICAL CHEMIST, RESEARCH INSTITUTE OF THE CANCER HOSPITAL (FREE), LONDON

Dr. Berenblum has been kind enough to show me the above note in manuscript. Under the circumstances it was thought advisable to communicate the experience obtained in this laboratory in the matter, although we had not intended to do this until the results of biological experiments with the material were forthcoming.

The production of sarcomata by the injection of solutions in lard and in olive oil emulsions of 1 : 2 : 5 : 6-dibenzanthracene, has been described by Burrows, Hieger, and Kennaway,[1] and by Burrows.[2] Mr. Burrows is now testing the possibility of producing tumours by injection of aqueous colloidal solutions of hydrocarbons containing no fatty solvent.

The solution is made by dissolving 0·3 g. purified 1 : 2 : 5 : 6-dibenzanthracene in 100 c.cm. acetone which has been dried over anhydrous Na_2SO_4 and redistilled. A solution of 0·5 per cent. leaf gelatin in distilled water is prepared by warming the gelatin in water on the water bath. One part of the acetone solution is poured into ten parts of warm (40–50° C.) gelatin solution with rapid stirring. The opalescent liquid is then boiled until the acetone is removed. The solution so obtained is stable for long periods, apparently at all temperatures. It can be sterilised by boiling, and a solution which has stood in the laboratory for three months has not produced any precipitate.

Colloidal solutions of lower concentration can be produced if the acetone solution of the hydrocarbon is poured into water. Gelatin was used as protective colloid to allow a greater concentration. The colloidal solution in water without protective colloid is very stable to heat and electrolytes. The particles of hydrocarbon have a negative charge, which might be explained by the dissociation of hydrogen ions from the hydrocarbon molecules. Some other hydrocarbons, such as anthracene, naphthacene, acenaphthene, and 1 : 2 : 5 : 6-dibenzphenazine—a substance with a molecule of similar shape to that of 1 : 2 : 5 : 6-dibenzanthracene—do not form colloidal solutions so easily in this way. 1 : 2-benzanthracene, chrysene, and dihydroanthracene do form colloidal solutions. It is possible that this ability to form colloidal solutions is necessary for carcinogenic activity, in that it would allow the material to penetrate into the cells. But the relative efficacy of aqueous and fatty emulsions in this respect remains to be decided.

CONFUSIONAL INSANITY FROM PSYCHIC SHOCK

By D. N. Parfitt, M.D. Lond., B.Sc. Wales, D.P.M.

SENIOR ASSISTANT MEDICAL OFFICER, WARWICK COUNTY MENTAL HOSPITAL

The early differentiation by Meynert[1] and Chaslin[2] of a type of insanity marked by confusion, with restlessness and disorientation, and very often eminently curable, has been followed by numerous descriptions of the possible factors in the production of such a psychosis. It has been shown that focal infection, cardiorenal degeneration, malnutrition, puerperal toxæmia, anæmia, glandular dysfunction (especially of the thyroid), and many other disorders may each be the chief cause of this kind of mental breakdown.

The importance of emotional factors such as domestic and economic stress, worry, fear, and anxiety has also been frequently pointed out, and cases have been recorded where some totally unexpected situation has seemed to precipitate a psychosis of purely psychogenic origin. Such cases have been described by Féré, Séglas and Barat, Hesnard, Stierlin, and others,[3] but examples of purely psychogenic psychoses of a confusional type have been sufficiently rare to warrant the recording of the following case.

Mrs. A., aged 49, had a serious love affair when a young woman; but her lover left for London and she heard nothing of him for more than two years. She gave up hope of seeing him again and married elsewhere. Later the lover returned, too late, and some time afterwards he also married. She saw no more of him for over 20 years, but after this, by a coincidence, it happened that the two families came to live comparatively near each other, and at this time the patient had a grown-up son and her former lover a grown-up daughter. The woman had always regretted her early marriage and her buried love found new life and happiness when the two young people fell violently in love. This happy state continued for some time, but eventually a rift occurred in the love lute of the young people which led to an acrimonious quarrel between the girl and her father on the one hand, and the son on the other. The first intimation the patient received of this unfortunate break was a bitter and hostile letter from her old lover, and the effect was the immediate precipitation of a psychosis. She became acutely anxious and restless, exhibited depression with much emotion, and heard hallucinatory messages telling her that her son was in great danger. Confusion with disorientation rapidly developed and she was certified and sent to hospital in two days.

With mild sedatives, simple persuasion, and sleep in an open verandah she rapidly regained stability and control and was discharged quite well in 35 days. Twelve months later she was still in very good health.

During her stay in hospital nothing abnormal was found on physical examination. The blood pressure at first was 125/82, the pulse-rate 80, later it rose to 140/90 and the pulse-rate became a little slower. The patient was successively examined by a gynæcological surgeon, an ear, nose, and throat surgeon, and by a dentist, and although the last extracted a few teeth no possible ætiological factor was found nor was any septic focus discovered at any time. The Wassermann reaction was negative in the blood and cerebro-spinal fluid, and the colloidal gold curve and cell count of the latter were normal.

The urine showed a trace of albumin in one specimen and a trace of indican in another, but was otherwise found free from all abnormality on several occasions. A urea-concentration test was quite satisfactory and the blood-urea on the second day was 35 mg. per 100 c.cm.; on the thirty-fourth day it was 34 mg. A fractional test-meal gave figures within normal limits.

A blood-sugar curve obtained on the fifteenth day gave a fasting level of 95 mg. per 100 c.cm., and after 1, 2, and 3 hours the blood-sugar levels were 170, 180, and 145 mg. respectively. In the absence of any organic disease this delayed return to normal, giving a hyperglycæmic index of 100, supports the emotional tension theory of McCowan and Quastel [4] and the only other abnormality discovered—namely, the excretion of only 7 oz. of urine in three hours after the ingestion of 1 pint of water on an empty stomach (water-excretion test of Strauss-Graunwald [5]) is probably explained by a similar mechanism. This test was carried out on the fourth day, and the same test repeated on the thirtieth day gave a result of 15 oz.

I wish to thank Dr. A. T. W. Forrester, medical superintendent, Warwick County Mental Hospital, for his permission to publish the notes of this case.

MEDICAL SOCIETIES

HARVEIAN SOCIETY OF LONDON

AT a meeting of this society on Nov. 9th, with Mr. C. P. G. WAKELEY in the chair, Prof. GREY TURNER delivered an address entitled

"Nil Desperandum"

illustrated by lantern slides. His intention, he said, was to show some surgical cases which might well have been viewed with despair, but in which surgical intervention had turned out to be fully justified.

1. A miner, aged 32, had come under observation at the end of 1931. At that time he was thought to be dying from intestinal obstruction due to a secondary deposit of malignant growth. He had a sarcoma of the suprascapular region which had been twice removed and once treated by radium, but which had recurred each time, and was suffering from severe pain and vomiting; the surgeon who was attending him thought that there were signs of secondary deposits in the chest, and that another deposit was responsible for his abdominal symptoms. Prof. Grey Turner, who was consulted, agreed with this view but was unwilling to let the patient die in such misery. Operation was undertaken, and when the abdomen was opened a chronic intussusception was found. The bowel tore during an attempt at reduction, and the apex of the intussusception was found to be a polypoid mass, which on subsequent section proved to be non-malignant. The patient was so ill that the involved loop of bowel was merely pulled out of the hole, and a lateral anastomosis made; he did fairly well, however, and the loop was subsequently cut off with the cautery, the two ends having been ligatured below the anastomosis. A fæcal fistula developed, which had to be closed later by operation, and the patient then said: "What about this lump on my shoulder?" No signs of secondary deposits could then be found in the chest, so the tumour was widely resected. The patient had made a complete recovery and was now back at work.

2. A girl of 19 had had gastric symptoms for three years which culminated in the perforation of an ulcer of the lesser curve. Operation for this emergency was performed in 1910, the ulcer was closed, a posterior anastomosis made, and the pelvis drained. Later, the patient married, and two years afterwards was confined with her first child. Labour began on a Sunday morning, and as everything seemed to be straightforward, her doctor left her for several hours and returned at 9 o'clock in the evening. He then found her in a state of severe shock. Prof. Grey Turner was consulted; the patient's abdomen was opened at once, in her own home, and Cæsarean section carried out as a preliminary measure; unfortunately the child was dead. Blood-stained fluid was present in the abdomen, and when the child had been removed it was possible to see that a large part of the small intestine was black and beyond hope of recovery, owing to thrombosis of mesenteric vessels. The damaged portion of gut was excised, and an end-to-end anastomosis carried out. In spite of a high temperature and an abscess at the site of a saline injection given by the nurse, the patient made a gradual recovery and three years later was delivered of a healthy child.

If perforated gastric ulcers could be operated upon early enough it should be possible to do a large number with a very low mortality. Every effort should be made to reduce the mortality by aiming at closer coöperation between the surgeon and the general practitioner.

3. A patient had had a history of recurrent ulcers. He was operated upon at the age of 13 for ulcer of the anterior stomach wall, at 16 for ulcer of the posterior wall, and again at 17 for an indurated ulcer of the anterior wall in front of the hilus of the spleen. Twenty-one days after this third operation he had an acute attack of pain. The abdomen was opened, and it was found that a perisplenic abscess had ruptured into the peritoneal cavity. The abdomen was swabbed out, and an anterior gastro-enterostomy performed; 29 days later the patient had acute intestinal obstruction from a band, and that too was put right. He recovered and served throughout the war in good health. Since the war he had had two attacks of obstruction which had recovered without operation, and one attack of hæmatemesis, but he was now perfectly well.

4. A farmer, aged 77, ruptured a duodenal ulcer, and was operated on in his home. A Keith's tube was put into the pelvis, and a few days later a large mass of intestine escaped through the suprapubic opening; this was returned to the abdomen, a tear in the gut being repaired hastily, and the wound was closed. The opinion of an elderly female relative that "he was too wicked to die" proved to be correct. Three years later he had an acute attack of osteomyelitis from a site in the tibia which had lain dormant since he was 10 years old. He survived that, and died at the age of 83 from mild cardiac degeneration.

The mortality-rate of operation for the radical cure of simple hernia was less than 1 per cent., but for strangulated hernia the operative mortality was 18 to 20 per cent. All patients with vomiting and abdominal pain should be examined for hernia; a small swelling in the groin of a fat woman was easily missed, but it was important to make a diagnosis and to operate; when anything at all went wrong with a hernia operation should always be performed. Strangulation might be at the hole in the peritoneum, not at the hole in the abdominal wall. Patients might get attacks of strangulation which they were able to reduce themselves; then came an occasion when they reduced the hernia into the cellular tissue instead of into the abdomen, and symptoms of obstruction persisted. Fæcal vomiting ought to be eliminated from text-books as a sign of intestinal obstruction; it was a sign not only of obstruction but of approaching death, and the diagnosis ought to have been made long before it appeared.

5. In a patient, on whom two operations had been performed for recurring volvulus, the adhesions, developing after the second operation, were so strong that complete resection of the colon became necessary; in spite of the development of a fæcal fistula which had to be closed, the patient made a complete recovery, and 24 years after the operation was still well.

Gall-stone ileus was a condition which must be borne in mind as a cause of intestinal obstruction. The symptoms were early and copious vomiting which soon became intestinal; there was usually incomplete obstruction in the early stages, the patient often passing a motion, and there were marked periods of intermission; the maturation of the recurring symptoms, however, was very rapid. It was extremely important to see the vomit. He described two cases of the kind, in one of which the remission of symptoms was so marked that the patient was unwilling to go into hospital for observation; fortunately she stayed overnight, when a severe attack developed and operation was performed.

Cases of peritonitis which at operation appeared to have no obvious cause were generally due to the leaking of a perforation, which must be carefully sought. He was convinced that phlegmonous enteritis ought to be treated by resection of the affected gut. He had treated many cases of ectopia by transplantation of the ureters into the rectum, and showed a slide of a patient in whom he had transplanted the ureters into the sigmoid 20 years before. The patient was perfectly well and comfortable, and could go for eight hours without emptying the rectum. Another patient, a woman with epispadias, in whom he had performed this operation, had subsequently married and given birth to two healthy children. Radiography showed that in these cases there was a condition of natural symphysiotomy, so that labour was particularly easy. There appeared to be no disability associated with the bony condition; one boy with an extremely wide gap, anteriorly between the pubic bones, was able to play football.

Prof. Grey Turner had performed plastic operations for hydronephrosis, and if there was no pre-existing infection the patients did well. This operation had proved particularly valuable in the case of a girl who had only one functioning kidney, and that hydronephrotic. Wheelhouse's operation was useful in cases of stricture, but many surgeons lacked the patience to do it. Before undertaking it, a sound night's rest and a good breakfast were needed. For rupture of the urethra a local operation was often successful; the roof and sides should be stitched and the floor left open. It was never too late to deal with a urethral stricture; he had performed Wheelhouse's operation with success on a case which had had a suprapubic fistula for 15 years. Surgeons were now getting better results with epispadias and hypospadias, and we must not regard such cases as hopeless. He described a case in which stricture of the œsophagus in a boy had been treated by making a vertical incision through the œsophageal wall at the level of the stricture, and stitching it together again transversely. If necessary, an œsopho-gastrostomy could be performed in such cases. The surgery of cancer was full of encouraging results, and if there was no certain dissemination of growth the patient ought always to be given the chance which an operation offered. He described cases in which wide resections of intestine and complete gastrectomies had resulted in a new lease of life for the patients. Gross surgical treatment ought to be followed up by supplementary treatment; he believed in the value of Coley's fluid as a prophylactic in sarcoma, and in selenide of lead in carcinoma. In nerve surgery, injuries occurring at all ages ought not to be classed together; in young people, where the nerves were growing, the results were much better than in older people. Nerve anastomosis might lead to some recovery of function even if the nerve-ends had been left divided for some years. The work of surgeons went to show that few injuries were too terrible to be recovered from, and we must never lose hope.

A vote of thanks to Prof. Grey Turner was proposed by Mr. Gordon Taylor, and seconded by Dr. G. de Bec Turtle.

MEDICAL SOCIETY OF INDIVIDUAL PSYCHOLOGY

At a meeting of this society in London on Nov. 10th, with Prof. W. Langdon Brown, the President, in the chair, a paper on

Psychology in Gynæcological and Obstetric Practice

was read by Dr. J. S. Fairbairn. One of the outstanding needs of medical practice at the present time, he said, was its infusion with the tenets of psychological medicine. To see any case in correct perspective the patient must be regarded as an individual with a mind as well as a body. Recent increase in the knowledge of pathology, with its accurate classification of the processes of disease, had led, however, to a concentration on the disease and a decrease in the consideration given to the personality of the patient. Gynæcological practice illustrated the dangers arising from this attitude; over-operation, for example, had taken place because the bodily condition alone had been considered and the mind ignored. Mental states, however, such as fear, or lack of confidence or self-control, were the most common causes of disordered action of the uterus in the otherwise normal patient, and they affected lactation even more obviously, so that the nervous woman is always regarded as a poor nurse. The unwilling mother was a hopeless problem; some enthusiasm must be roused to obtain even moderate success.

Disorders of menstruation might have a local pelvic, a general constitutional—e.g., metabolic—or a psychical cause, or all three might have a share in producing the disturbance. They were therefore especially instructive instances of the need for the thorough investigation of the patient as a human being with social relations—something more than an anatomical specimen of mankind. Dysmenorrhœa was largely mental in origin. Dissatisfaction with the feminine rôle might play a part, but the suggestion of menstruation as an illness, and its usefulness as an excuse for failure or the avoidance of doing what is uncongenial, satisfied him as an explanation for most cases. Dyspareunia seemed to be largely a defence against pregnancy.

The abdomino-pelvic ailing woman, with a degree of disability difficult to correlate with the physical condition, formed an extraordinarily difficult problem, and was very commonly encountered. Dr. Fairbairn believed that operation for the abdominal or pelvic laxity so often present was advisable only if it would make a change so material as to be obvious to the patient.

Dr. Fairbairn gave fatigue an important place, or what (as a diagnosis for his students) he called the "tired mother." This name applied to women socially above the hospital class, who, being unable to afford domestic help, devoted themselves to the maintenance of the respectability and credit of the family. The husbands characteristically exhibited the same love of respectability, but were also very ununderstanding.

Dr. F. M. Edwards touched upon the stresses which may produce dysmenorrhœa; she cited a case in which profuse periods coincided with the possibility of marriage, and another where the same symptom had a definite symbolic value.—Dr. H. C. Squires remarked that similar reactions to stress occurred in white, black, and brown people. Women in the East had particular difficulties.—Dr. T. LAWSON pointed out that just as an infant wishes to compensate for inferiority, so does an adult. The irrationality of disease is explained by considering the line along which he is acting. He regarded dysmenorrhœa as a masculine protest, and he suggested that the "tired mother" can be explained by the wish for appreciation.—Dr. H. C. WOODCOCK said that Adler's view that marriage is a task for two people suggested that premarital as well as prenatal instruction should be undertaken.—Dr. F. G. CROOKSHANK pointed out that behind the definite symptoms a problem was always present which must be dealt with. The neurotic reaction was determined by the person's life style, and the organ inferiority which was relevant.—The PRESIDENT also spoke of the importance of organ inferiority.

Dr. FAIRBAIRN said in reply that the symptoms of the "tired mother" was an indication that she recognised her poor position. He said that he had had a case similar to those which Dr. Edwards had mentioned. Irregular hæmorrhage occurred after a secret marriage, and ceased when the patient made her marriage known.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY

AT a meeting of this society held in Liverpool on Oct. 28th, Dr. E. A. GERRARD (Manchester) read a paper on

Epithelioma Vulvæ in Cotton-spinners

While many writers had suggested possible factors in the causation of epithelioma vulvæ—e.g., leukoplakia vulvæ, syphilis, and trauma—no one, he said, had made any observations on the true underlying cause except to suggest that it was some form of chronic irritation. He had inquired into the occupations of 373 patients suffering from this condition, and of 101 cases in which a full history was obtained 59 per cent. were found to be working, or to have worked, as cotton operatives. Of all women over 20 years old admitted to two representative hospitals, the percentage of cotton operatives was only 28. An attempt was made to establish the influence of mineral lubricating oil as a causal factor, in view of the known effect of this substance among male cotton-spinners, and certain facts were elicited. In the case of cotton-spinners the air of the mill contains oily fluff and the spinners' hands are always oily. In the case of weavers the hands are oily and the act of sweeping the looms with an oily brush, sometimes in a squatting position, suggests the possibility of transference of oil to the external genitalia. Investigation of the occupation of 27 husbands of women who had not worked as operatives showed that in 10 there was a possibility that oil might be a causal factor. A further investigation of cases in a Yorkshire town showed that 73 per cent. of those suffering from epithelioma vulvæ were woollen operatives and ex-operatives.

Trichomonas Vaginalis

Mr. PERCY MALPAS reported that he had investigated 100 consecutive gynæcological cases and had found trichomonads in 11, though only in 4 were they present in large numbers. They were found in 36 per cent. of the cases of leucorrhœa. He described the method of detecting trichomonads by examining discharge, mixed with normal saline on a slide, using a $\frac{1}{6}$ in. objective. The typical appearances were the refractility and characteristic movements. The discharge in cases of heavy infection was foaming and resembled cuckoo-spit, while mucus was absent. The trichomonads could only be cultured for a few days, because of the presence of a heavy bacterial infection. On the disputed question of the pathogenicity of the organism, he mentioned three propositions:

(1) That the *Trichomonas vaginalis* is the prime cause of some cases of vaginitis. Against this contention are the facts that in cases of leucorrhœa, the trichomonads are never found except in conjunction with bacterial infection, and further, that the organisms may be found accidentally in enormous numbers in cases with little discharge and no symptoms.

(2) That the trichomonas is a harmless saphrophyte.

(3) That the organisms may so modify the discharge as to aggravate the symptoms.

Mr. Malpas favoured this last view. No form of treatment, he said, appeared to be specific, for although the organisms could be easily destroyed by simple antiseptic measures, they often reappeared.

Mr. W. W. KING (Sheffield) had found that the discharge when this infection was present varied greatly and might be almost absent, and he agreed as to the absence of mucus. He mentioned as diagnostic points the facts that the introitus vaginæ and vaginal walls might be spotted with small red and shiny areas ("strawberry vagina") and that the rugæ were swollen.

Mr. King showed a specimen of ruptured tubal pregnancy in an accessory tube, and Mr. R. WATSON (Liverpool) described a case of prolapse of a pregnant uterus through a tear in the posterior vaginal fornix, in a 5-para, aged 41.

Mr. WILLIAM GOUGH (Leeds) recorded a case of congenital defect leading to fæcal impaction.

The patient was a girl, aged 17, whose general health was good but who had an abdominal swelling as big as a full-term pregnancy. Vulval examination showed the anterior part to be normal and the hymen unruptured. The fossa navicularis was deep and behind the hymen was a small orifice, only large enough to admit a lead pencil, from which liquid fæces could be seen escaping. After enlarging the opening by incision several pounds of solid fæces were removed and the intestines were emptied in three weeks.

An attempt was then made to form a sphincter by an operation similar to the repair of a complete perineal tear, using the two halves of a transverse bar of fibrous and muscular tissue that was palpable immediately behind the orifice.

LIVERPOOL MEDICAL INSTITUTION

AT a meeting of this institution on Nov. 3rd, with Prof. R. E. KELLY, the President, in the chair, a paper on

Surgery of the Lung and Pleura

was read by Mr. HUGH REID. Tuberculosis of the lungs, he said, healed by fibrous encapsulation. The most important factor in healing was individual resistance, and the next was functional rest of the diseased part. It was the object of the thoracic surgeon to bring about functional rest, and the three main factors with which he had to contend were: the elastic pull of the lung itself; the bony thorax, also constantly moving; and the muscle pull of the diaphragm. Artificial pneumothorax alone, by allowing the lung to collapse, was extraordinarily useful, and would arrest the progress of active spreading tuberculosis when every other conservative method had failed. But there were various difficulties, dangers, and complications of artificial pneumothorax. Thoracoplasty was often the only logical means of attempting to bring about functional rest. Phrenic avulsion had a wide range of usefulness, both in itself, as a preliminary to some other procedure, and for the relief of symptoms.

Dr. Dennison Pickering said that, in considering surgical treatment of the lungs and pleura from the point of view of a private sanatorium, two questions must be answered—whether and when? Whereas some physicians deprecated any surgical measures at all, others would adopt them, without delay, wherever possible. Dr. Pickering advocated an intermediate course; a reasonable time should be allowed for conservative treatment before proceeding to surgical measures. Hæmorrhage might compel interference, while the presence of cavities, or recurrent pleurisy, would suggest the inadvisability of losing time. It was important to avoid the mistake of spending three or four months on conservative treatment, only to find the patient too weak to undergo operative treatment which at an earlier stage might have been successful.

Dr. Robert Coope said that cavitation in a lung, at whatever stage of the disease, should call for very careful consideration of the various methods of treatment which might be to the patient's advantage. It was a responsible matter to select the right case for collapse treatment, and to advise the best form of obtaining collapse; from the very start physician, surgeon, and radiologist should have their thoughts on the particular case. Artificial pneumothorax, simple in its technique, was not quite so straightforward in its results; even in cases apparently ideal for it, disappointment might come from unexpected pleural adhesions, the development of pleural effusion with its consequences, or the onset of contralateral phthisis. Taking the field of phthisis as a whole, he thought it would be found that phrenic paralysis had a much wider usefulness; sometimes for direct collapse, often also for the relief of troublesome symptoms. It appeared to be as useful in apical as in basal disease.

Dr. Henry Cohen drew attention to the digestive discomforts which sometimes follow left phrenicotomy. These he attributed to interference with gastric motility resulting from paralysis of the diaphragm. He emphasised that unilateral phrenicotomy was not without danger if emphysema developed.

Dr. B. T. J. Glover spoke of the need for further effort on the part of the physician to prevent the advanced and distressing conditions which needed surgical intervention. He said that an allergic state resulted from the liberation of tuberculo-protein as the result of the death and disintegration of tubercle bacilli. Once this hypersensitiveness to tuberculin had been established, and unless it waned, allergic inflammation with tissue destruction took place at the periphery of the tuberculous lesions. This interference with the repair process resulted in continuously spreading disease. Instead of using tuberculin for the stimulation of perifocal inflammation, as was done formerly, it should be used for desensitisation purposes in the hope that the removal of hypersensitiveness would allow repair.

Warmed Anæsthetics

Dr. R. J. Minnit said he thought the heat loss during anæsthesia was largely caused by the inhalation of a vapour, which at the intake was below the temperature of the surrounding atmosphere, when at the same time the heat-regulating mechanism was interfered with by the action of the anæsthetic itself. He had devised a piece of apparatus for attachment to the McKesson machine for the purpose of heating gas and oxygen with or without ether. It consisted of two copper vessels, one inside the other, with copper fins connecting them so as to obstruct the circuit of the space between the vessels. The approximate distance the gases had to travel from the inlet to the outlet was 10 ft., and they were heated by boiling water placed in the container. An experiment undertaken at room temperature showed that the temperature of the vapour at the output of the heater was 120° F., and that it fell to 80° F. at a distance of 3 ft. of tubing. Without the heater, under the same conditions, it was 45° F. The apparatus could be used with either face-mask or intratracheal attachment, and the gases could be delivered at any temperature desired, according to the length of the delivery tube. Its advantages were that induction was more rapid and pleasant; a larger percentage of oxygen could be given in the mixture, so limiting cyanosis; and less ether need be used. Operative shock was diminished, and post-anæsthetic vomiting and chest complications were decreased.

Dr. A. A. Gemmell reported a case of carcinoma of the body of the uterus, in which the only symptom over a period of ten months was a watery vaginal discharge, so profuse that it was mistaken for urine.

LONDON ASSOCIATION OF THE MEDICAL WOMEN'S FEDERATION

At a meeting held on Oct. 25th Prof. Lucas Keene delivered her presidential address entitled

Anatomy, Now and Then

She began by showing photographs of sculptures of very early date, and drew attention to the fact that an artist who renders the human form in true anatomical detail is an anatomist, however unwitting or unscientific. She deprecated any attempt to draw definite conclusions as to the state of anatomical knowledge from the anatomy depicted by any small group of works of art of a period, showing by photographs that wrong conclusions would necessarily be drawn were the state of present-day anatomy judged by the anatomy of figures sculptured by a certain well-known artist. She sketched the work and achievements of the greatest of anatomists through the ages, and gave some excerpts from recent work to show that the modern trend of anatomical thought is not entirely divorced from practical medicine. She concluded by expressing appreciation of the honour of election to the presidential chair, realising that in asking an anatomist to preside over their meetings they did so in recognition of the debt owed by medicine to the great anatomists of old.

Royal East Sussex Hospital.—On Nov. 2nd Princess Alice Countess of Athlone paid a visit to Hastings to receive purses; nearly £1200 has been collected for the new nurses' home. The new home is the last of the four projects which were outlined in an appeal launched in 1928: the reduction of a bank overdraft, the erection of orthopædic and isolation wards, the equipment of the children's ward and the erection of a sunshine ward have already been carried out. Princess Alice also unveiled a plaque commemorating the acquisition of the grounds which the governors have secured as the site for the home. The work of reconstruction will be done in convenient stages.

REVIEWS AND NOTICES OF BOOKS

The Extra Pharmacopœia of Martindale and Westcott

Revised by W. HARRISON MARTINDALE, Ph.D., Ph.Ch., F.C.S. Twentieth edition. Vol. I. London: H. K. Lewis and Co., Ltd. 1932. Pp. 1216. 28*s*.

AN official Pharmacopœia must be conservative in its outlook, refusing to admit to its pages new drugs the efficacy of which is not completely established. In the intervals between the production of successive Pharmacopœias, it is important that there should be some volume which will give information regarding the trend of therapeutic measures, and will help to crystallize opinions on the action and uses of drugs. The Extra Pharmacopœia of Martindale and Westcott has worthily filled that rôle for the past half century, and is so well known to the profession that it is almost unnecessary to do more than draw attention to the fact that a new and up-to-date edition is now available. It contains more information on all aspects of drugs than any book of its kind; the labour of compiling it must have been enormous. Official and non-official drugs, special preparations, many of which are unknown to all but a few of the profession, are arranged in alphabetical order, and a comprehensive summary of the latest information derived from the ward and the laboratory is given.

It is impossible, of course, for the author to adopt a dogmatic attitude towards the claims made for every new preparation put on the market, and the work might therefore be assailed on the ground that it is uncritical. Chapter and verse are given, however, for most of the statements made, and the reader can always refer to the original literature and draw his own conclusions. The new edition has been thoroughly revised to bring it into line with the advances in chemistry and therapeutics during the past four years. To mention only a few of the notable changes: the coal-tar derivatives now include phenylhydrazine, used in certain blood diseases, pyridium and neotropin as urinary antiseptics, and percaine, a new local anæsthetic. The employment of acetylcholine in various forms of arterial spasm is discussed, and new information is available regarding the basal hypnotics. The article on ipecacuanha has been rewritten, but it has to be confessed that in spite of the new compounds, auremetine and emetine periodide, the ideal drug to rid the intestine of amœbæ in the more chronic forms of dysentery is still to find. A very complete chapter on the nutrimenta gives the latest information on meat and milk preparations, graded milks, new infant foods of British manufacture, diabetic foods, and the accessory food factors. Important additions to organotherapy are the employment of heart-muscle extracts for angina pectoris, ovarian hormone preparations, and extracts of the cortex of the suprarenal glands. Apart from drugs, a great deal of information is offered to physician and pharmacist on many aspects of their respective crafts. Vaccines and antitoxins, now official in the B.P., are adequately discussed, and comparison is made with the corresponding doses and strengths in new foreign pharmacopœias. There is an article on blood transfusion; and an intravenous dose table and a therapeutic index of diseases and symptoms are included.

For those engaged in commerce, the plan of showing whether a preparation is a registered trade mark is a valuable feature, while exact information is afforded on the poisons schedule, the Dangerous Drugs Acts, the therapeutic substances regulations, and many other legal and excise matters of importance to medical workers and makers of chemicals used in medicine. Few medical men can afford to be without this valuable work, and Dr. Martindale is to be congratulated on the energy and efficiency with which he carries on the task initiated 50 years ago by his father and Dr. Wynn Westcott.

Practical Anatomy

By Six Teachers. Edited by E. P. STIBBE, F.R.C.S., Lecturer in Anatomy, London Hospital Medical School. London: Edward Arnold and Co. 1932. Pp. 719. 30*s*.

WE welcome this addition to the number of dissection manuals. The "Six Teachers" of the title page are Profs. Wright, Yeates, Stopford, Whitnall, and Lucas Keene, with Mr. P. Stibbe, who acts also in the capacity of editor. This list of well-known anatomists and teachers is in itself a guarantee of the soundness of their product, which is essentially a practical work written by those accustomed to help students in the dissecting-room. We note that the authors see no reason for discarding the old terminology, which they employ, although they have open minds on the use of other nomenclatures. The illustrations are appropriate and useful; we would like to see many more of them, for the student is helped in several ways by such aids. The book seems to be remarkably free from errors and misprints. The inferior constrictor is mentioned (p. 528) where the middle muscle was intended; in Fig. 86 and its copy the word "bronchi" is mis-spelt, and the section of the spleen shown in Fig. 154 is given as its "naked appearance"—a list of slips so negligible that the editor deserves congratulation. Altogether a good-looking book, well produced and easy to read, which should achieve real popularity.

The Pneumococci and their Enzymes

Research Work on the Pneumococci and their Enzymes and its Significance in Lobar Pneumonia. By A. COWAN GUTHRIE, M.B. London: Baillière, Tindall and Cox. 1932. Pp. 60. 7*s*. 6*d*.

THE experiments recorded in this book were started by the author in 1919 and continued in 1926 and 1930, and, as he states in the preface, have been carried out whilst he was conducting a very arduous practice. The monograph has the limitations of one whose author has evidently had to labour under difficulties and without numerous animal experiments with which to check his results. After a brief introduction, in which Dr. Guthrie defines the ordinary terms used in immunology such as antigens, complement, and antibodies, he goes on to record a number of experiments made on the pneumococcus and immune sera. As a result of these experiments Dr. Guthrie holds that it is unquestionably the endotoxin of the pneumococcus which protects it against lysis by the leucocytes and phagocytes. The immune serum destroys this endotoxin. The endotoxins of the pneumococci contain primarily hæmatoxin, and the pneumococci protect themselves against leucocytes and other phagocytes by means of hæmatoxin, which has a lytic effect on erythrocytes and leucocytes. Dr. Guthrie also describes four enzymes of the pneumococcus.

Basing his treatment on these bacteriological premises Dr. Guthrie considers it imperative tha during the whole course of pneumonia the patient should be supplied with oxygen. He also holds that complement is the dominating influence in extracting the enzymes from the pneumococcus and that if the patient's complement is deficient in quantity or quality this deficiency should be rectified at once by the injection of fresh blood with the usual precautions. He advocates also the use of oleate of sodium with a view to the solution of the pneumococcus, and of the use of optochin and antibody solution in conjunction. He gives a short account of the intracellular enzymes isolated by Avery in America from what is called S. III. bacillus for decomposing the capsule of Type III. pneumococcus. This enzyme, Dr. Guthrie suggests, may become useful in the treatment of pneumonia. The book contains some photomicrographs of the leucocytes at various stages of the experiments and a very brief bibliography.

Heilsera und Impfstoffe in der Praxis

By Prof. R. Bieling (Frankfort) and Prof. F. Meyer (Berlin). Leipzig: Georg Thieme. 1932. Pp. 184. With 48 illustrations. RM.11.

This little book is one of a series, the purpose of which is to give the principles underlying the different branches of therapeutics in a clear and practical form. It deals with the therapeutics of sera and vaccines, and is written, as such an introduction should be, on the basis of a thorough practical acquaintance with the work of a serum laboratory. It explains simply the preparation and testing of sera, and, above all, their methods of standardisation. All the ordinary sera are briefly described, and their use in clinical medicine indicated with commendable caution. The authors, as one might expect, depart in one or two particulars from current British and American practice, but to those who find German no hindrance the book can be strongly recommended as a reliable introduction to a subject which too often falls into the hands of mystifiers. We know of no book in English of the same scope which is so well written.

Control of Conception

By R. L. Dickinson, M.D., and Louise Stevens Bryant, M.D. London: Baillière, Tindall and Cox. 1932. Pp. 290. 24*s.*

This book is produced under the auspices of the American Committee on Maternal Health in response to requests for a brief compilation of what is at present known concerning the means of, and medical indications for, the control of conception. The reader is informed in a preface that its two main claims to originality reside in the way it interweaves clinical observation with the facts of anatomy, physiology, and chemistry, and in the manner that it "faces the two medical responsibilities" allied to contraception—namely, therapeutic abortion and sterilisation. The first of these claims is fully justified. The available knowledge of the physiology of coitus, which is scantier than that of any other function of the body, is intelligently epitomised. About three-quarters of the book is devoted to a discussion of the problems of contraception, and it is this part which will be of most interest to readers in this country.

Like Dr. Dickinson's other works, this one is fully documented, is illustrated by well-executed drawings, and is informed by a long practical experience of gynæcology. The discussion of the comparative merits of the different methods of controlling conception is among the best that has yet appeared. Especially valuable is the section devoted to the sheath. In America, as in Europe, this method is more generally used than any other except coitus interruptus. The 15 chief manufacturers in America are reported to produce 1,440,000 of these articles a day, and, according to Dr. Harmsen, a leading German firm of manufacturers sells no less than 24,000,000 a year. Yet this method has been somewhat groundlessly disparaged in most of the literature that has appeared in this country. Since the failure of the sheath is often attributable to the use of articles that have perished, the author recommends that the date of manufacture be stamped on each sheath. The disadvantages of all existing methods are now well recognised, and the researches in progress in this country and America with a view to discovering simpler and better ones are well summarised here. The book also contains chapters on the technique of abortion and of sterilisation.

Life in Nature

By James Hinton. Edited, with an introduction, by Havelock Ellis. London: George Allen and Unwin, Ltd. 1932. Pp. 291. 10*s.* 6*d.*

Seventy or eighty years ago some essays appeared in the *Cornhill Magazine* which when published as a volume met with a good reception, although the author, James Hinton, in his preface expressed modest doubts concerning the fate of his work. Hinton was aural surgeon to Guy's Hospital, had a large private practice, and represented well the clinical wisdom of his day, but he was far more distinguished as a philosopher than as a medical man, and "Life in Nature" thoroughly deserves republishing to-day. Mr. Havelock Ellis in an appreciative preface reduces the argument of the book to its simplest terms by reminding us how much materialistic interpretations of the phenomena of life upset the ordinary man in the middle of the nineteenth century. "To apply a 'materialistic' explanation to life seemed to deprive it of its glory, to kill what had been its special 'spiritual' exaltation, to reduce it to the low and common-place level which (except for poets at moments of unusual extravagance) characterised everything in nature outside life." Hinton's essays were a beautifully expressed intent to meet a prevalent disturbance of thought. In a loosely connected series of chapters he discusses the universality of life and the place of man in nature, and in a closing appendix supplies an attempt towards an interpretation of the laws of life. As lucid expositions of some of the more interesting questions which the known facts about living bodies suggest, certain of the arguments which he brought forward are necessarily not so valid as when they were originally stated, but this in no way detracts from the logicality of the arguments. Undoubtedly, Hinton was a real lover of wisdom. Writing about him in The Lancet shortly after his death, Samuel Wilks, his colleague at Guy's Hospital and in many ways a kindred philosophic spirit, said of the *Cornhill* essays: "They all show a train of thought which forbad him (Hinton) to grovel with details, but obliged him to link together and endeavour to harmonise the facts which he found in all dominions of nature. It is this which interests us, being the tendency of our modern thought. He knew not one 'ology from another, seeing they were but fictions of man's creating, but that all departments of nature were bound together by the same universal laws." These words in themselves justify the republication of "Life in Nature."

AN EMPIRE PRODUCTION

OF GREAT VALUE TO THE INVALID

Burgoyne's

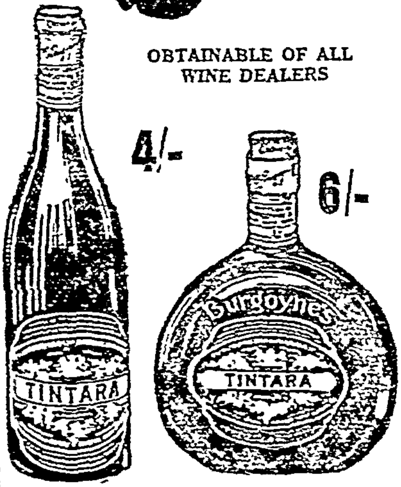
Tintara

Ferruginous

OBTAINABLE OF ALL
WINE DEALERS

4/-

6/-

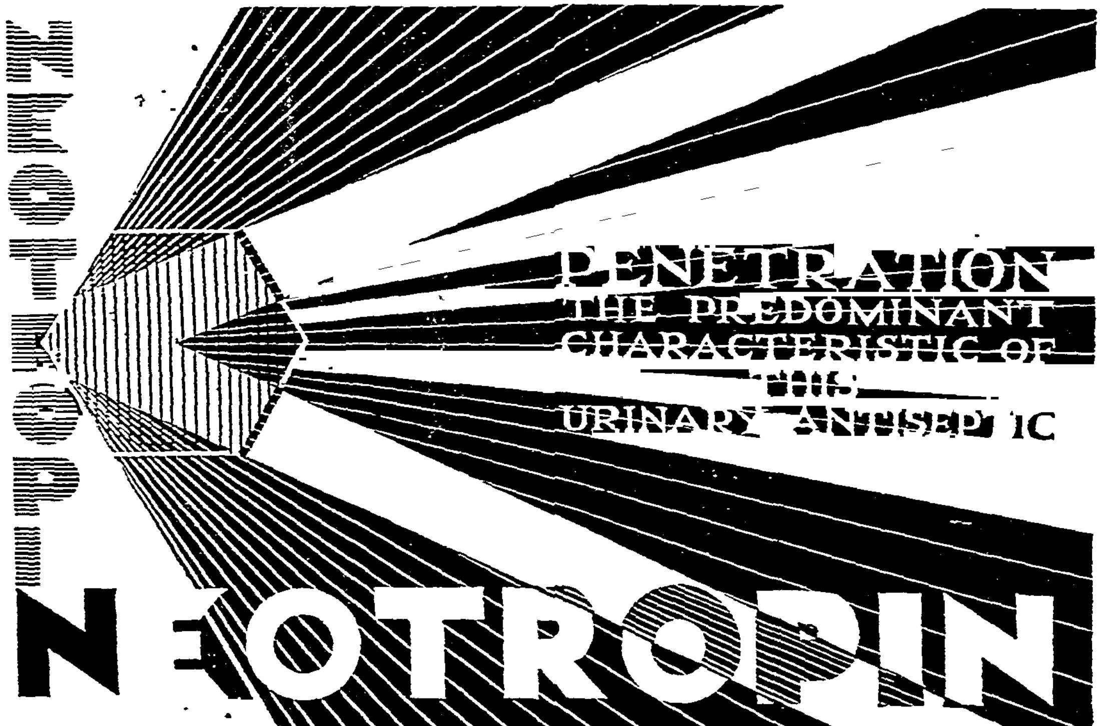


THIS PURE AUSTRALIAN WINE introduced in 1871, has been highly recommended by the Medical Profession in all cases where strength and nerve force have required building up. In anæmia, debility, neurasthenia, and in convalescence after any illness, this full-bodied, generous wine, palatable as well as health producing, has proved itself the finest of all natural stimulants.

Sample Bottle sent free in the United Kingdom, on receipt of professional card.

ABSOLUTELY PURE

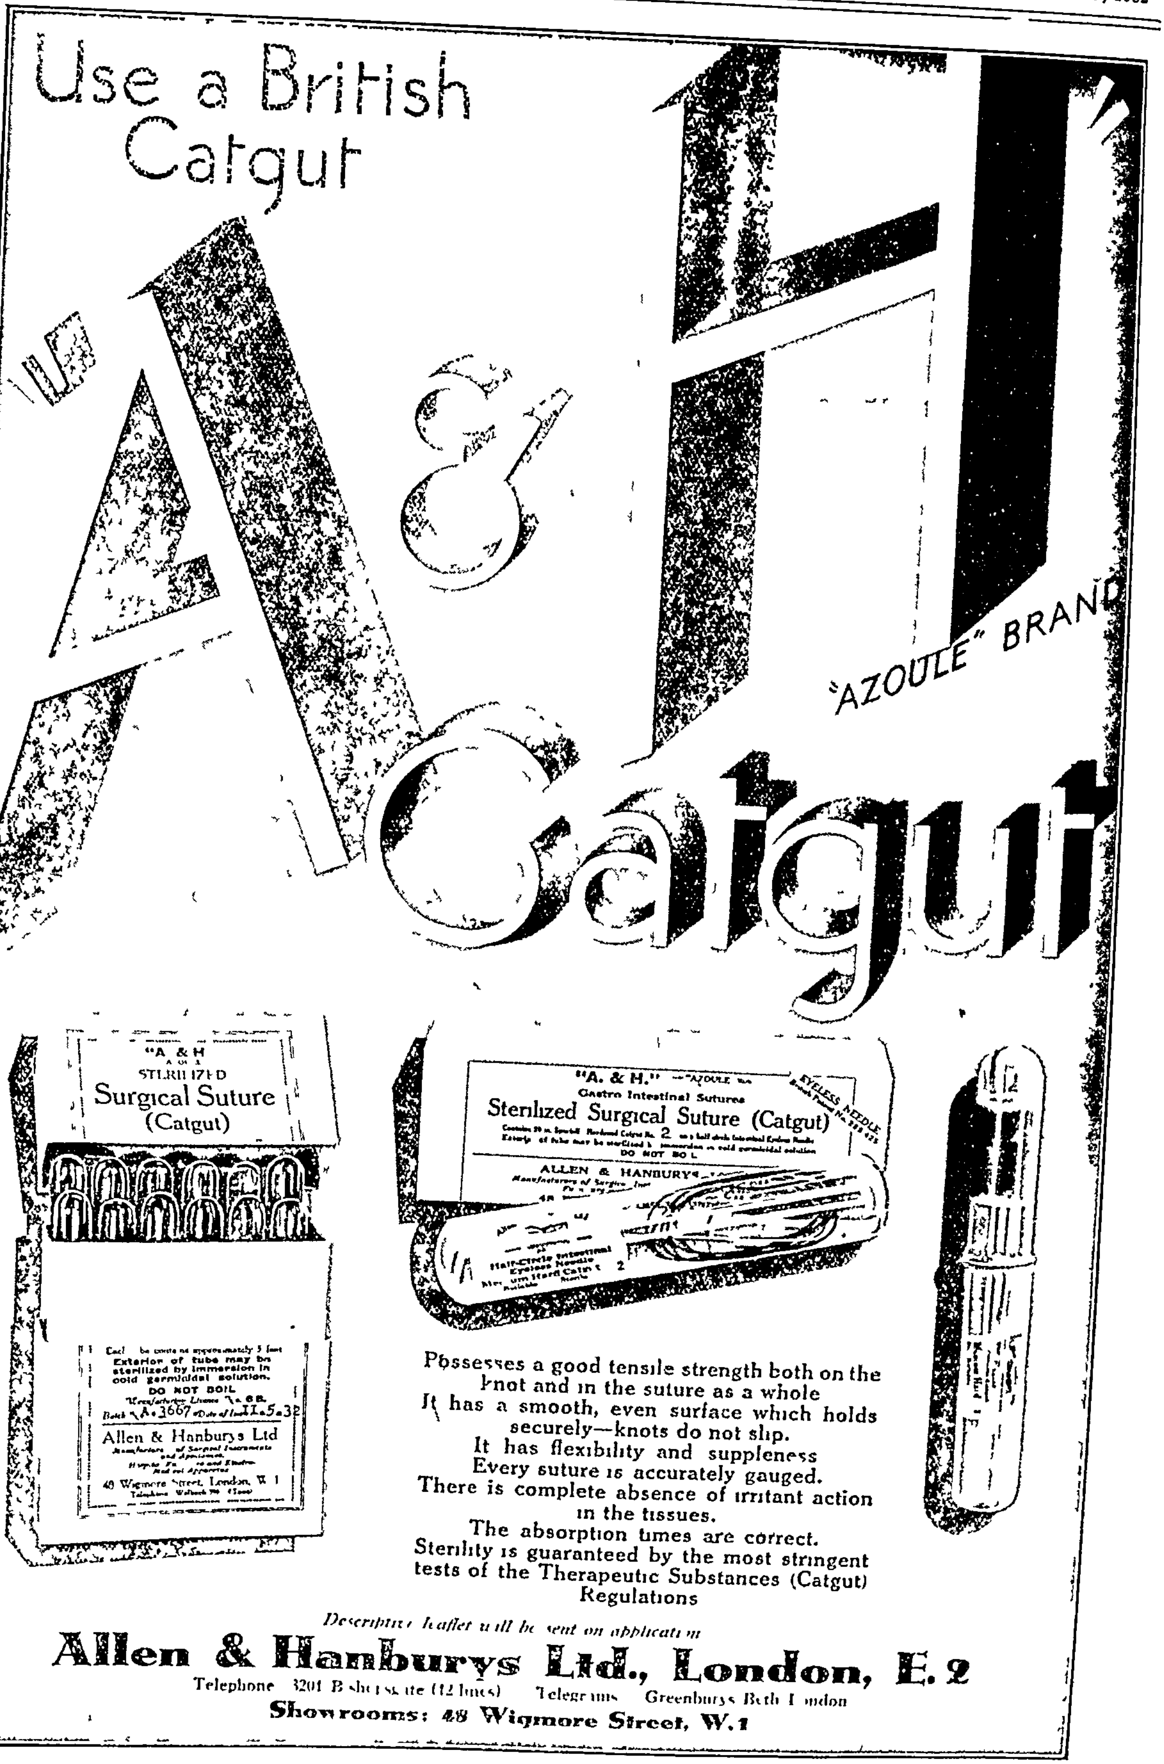
P. B. BURGOYNE & CO., Ltd.,
Burgoyne House, Dowgate Hill, London.



For oral administration. Bottles of 30 and 250 dragées (1.5 grains).

Sample and literature on request.

SCHERING LIMITED, 3, LLOYD'S AVENUE, LONDON, E.C.3.



Possesses a good tensile strength both on the knot and in the suture as a whole
It has a smooth, even surface which holds securely—knots do not slip.
It has flexibility and suppleness
Every suture is accurately gauged.
There is complete absence of irritant action in the tissues.
The absorption times are correct.
Sterility is guaranteed by the most stringent tests of the Therapeutic Substances (Catgut) Regulations

Descriptive leaflet will be sent on application

Allen & Hanburys Ltd., London, E.2

THE LANCET

LONDON: SATURDAY, NOVEMBER 19, 1932

THE NEGLECT OF WHOOPING-COUGH

THOMAS WILLIS in his classical treatise, "Pharmaceutice Rationalis," published in 1674, remarks that the management of whooping-cough was left mainly in the hands of old women and empirics. We have certainly advanced from that position, but perhaps not so very greatly. The serious aspect of this disease of childhood is still underrated by the public—and by the medical profession. Even a casual search of the literature shows how little attention has been paid to it in the field of public health. Yet during the decade 1921–30, whooping-cough was responsible in England and Wales for 44,000 deaths, that is slightly more than measles and more than scarlet fever and diphtheria put together. At ages 0–5 whooping-cough took fifth place during this decade in the list of causes of mortality. It is obvious from these figures that, in spite of the enormous improvement that has taken place in its contribution to the death-rate during the last three-quarters of a century, whooping-cough remains a killing disease. Moreover its significance to the life of the nation does not lie only in its mortality. In a study just published[1] by Dr. PERCY STOCKS (assisted by Miss MARY KARN), it is estimated that during 1926–30 there was in London an average annual incidence of about 40,000 cases, and that more school time was lost through whooping-cough than through measles. Far more important than this, as Dr. STOCKS points out, is the toll of impaired physique, the cardiac damage which cannot even be guessed at, and in severe cases the possible psychological trauma due to "the incessant terrifying paroxysms with their sense of impending suffocation"—a factor to which so far no attention has been paid.

The material which Dr. STOCKS has studied has been mainly drawn from four London boroughs—Greenwich, Wandsworth, Holborn, and Battersea—in which compulsory notification of whooping-cough was in force. After a discussion of its fatality, which falls mainly upon children under 2 years, and decreases rapidly with age, and of its periodicity, biennial in Greenwich and Battersea, he turns to the population at risk in relation to the periodicity of the disease. The epidemic cycle in whooping-cough has usually been assumed to be accounted for either by (1) the fact that there is some cycle of activity of the bacillus influenced by seasonal conditions, or (2) that epidemics begin when sufficient children have accumulated who have not previously had the disease and terminate when this surplus of susceptibles has been depleted. The first of these assumptions was examined by MATTHEW YOUNG,[2] whose work hardly supported the theory since the period was not identical in different towns; to which STOCKS adds the difficulty of believing that the cycle could be in a different phase by several months in two areas of London streets whose populations were continually mixing with each other. The second hypothesis is shown in this paper also to be untenable. Calculation of the number of children not attacked shows that there may be no greater proportion of susceptibles in the population when an epidemic is starting than when one is ending, and at the same time of year. This result is in agreement with American figures published by SYDENSTRICKER,[3] which showed that an epidemic ceased when the total non-immune population not only was not exhausted, but had been reduced by as little as about one-fifth, "in spite," he says, "of the fact that opportunity for contact was afforded under the usual conditions of urban life, and that no effort to control the infection was exercised by the community, except to exclude cases from the schools after they had become clinically manifest." On the other hand, Dr. STOCKS produces evidence in favour of the explanation both of the termination of epidemics and of their periodicity by the occurrence of a latent immunisation of contacts as in measles, such immunity only lasting about one year instead of two or three. The occurrence of such a transient latent immunisation is indicated by (*a*) the measurement of the rise and fall of apparent infectiousness of cases to other children in the same house over a period of six years in Battersea; (*b*) the measurement of the frequency of second cases in houses after different intervals of time during a decade in Greenwich; and (*c*) an analysis of the attack-rates amongst home contacts in Holborn and Battersea during several years following exposure to infection as compared with those among control groups of children. This analysis, which requires some mathematical reasoning, suggests the broad conclusion that for every 100 children who have recognisable whooping-cough during an epidemic, at least 100 escape by acquiring a transient latent immunity, while another 300 escape either by the same process or by virtue of an inherent passive immunity, and the remainder by having had the disease or by avoidance of infection.

These findings are similar to those of the same author for measles, with certain differences. Whooping-cough is seen to have a longer epidemic period: the period of conferment of latent immunity is shorter; the proportion of children attacked at some time during life is smaller—about 60 per cent. instead of 90 per cent. in measles—rendering probable the existence of a certain proportion with inherent immunity which is not apparent in measles; and, finally, the ratio of latent to manifest infections is lower in whooping-cough. It is to be hoped that Dr. Stocks's careful study will lead to the payment of increased attention to what is, at present, one of the most serious of the infectious diseases of early childhood.

◆

DIET IN DIABETES

Nearly four years ago[1] a correspondent in our columns drew attention to the opinions and results of Prof. Wilhelm Falta, of Vienna, who had long advocated the use of higher carbohydrate diets in the treatment of diabetes. Although a few workers in this country had been allowing their patients more carbohydrate, with insulin, it was not until 1930 that interest in this method of treatment became general, and the belief in extreme restriction of carbohydrates began to give way. Since then most of the authorities, both in England and America, have spoken encouragingly of the newer form of diet, and though the change of opinion was slow at first it has lately become rapid. Nor is this change a slight one. For many years after the discovery of insulin diabetic patients were kept strictly to an abnormal diet, and an allowance of carbohydrate greater than 60 g. a day was rare except in the mildest cases. On such diets constant attention to the intake of both carbohydrate and fat was necessary, and when still smaller quantities of the former were allowed the risk of acidosis was always present. A typical diet, laid down less than four years ago, would have read: carbohydrate, 50 g.; protein, 70 g.; fat, 130 g. To-day the quantities of fat and carbohydrate have been reversed by many physicians, so that the figures might read: carbohydrate, 200 g.; fat, 60 g. The main cause of so violent a reaction against the older practice is that the results it gave were not found to justify the difficulties and disadvantages of its application. It was thus not uncommon to find, as it was put in one discussion,[2] that patients who either could not or would not adhere to a low carbohydrate diet did as well or better than those who rigidly obeyed their doctors' orders.

When the carbohydrate is considerably increased it is found that a very small addition to the insulin allowance is often sufficient to maintain the urine free of sugar; in some cases two or three times as much carbohydrate can be taken on the same or even a lower insulin dosage. The use of such higher carbohydrate diets with insulin is a material gain from the patient's point of view, because he is able to take a simpler and more physiological diet. Many clinical reports show also that he feels better. As regards the effect on the disease itself it is perhaps early yet to judge, but a good deal of evidence points to some improvement under the new régime.[3] It is certain, however, that the total amount of carbohydrate allowed, if covered by insulin, is not the only factor concerned in the treatment of diabetes. The total calorie intake is certainly important, especially in elderly patients who have a tendency to obesity. The proportion of fat which should be given is still a matter for discussion, though Falta and others hold that large variations have little or no influence upon the hyperglycæmia or glycosuria. Clearly unless evidence is strong that a low fat intake is beneficial it is to the great advantage of a high carbohydrate diet that fats may be taken at the patient's own discretion, without risk of ketosis, so that only the carbohydrates require weighing.

The diet which seems to be proving most suitable for the diabetic is the one which, with the help of insulin, most nearly approaches the normal. It is reasonable to conclude that the work of the last few years has shown that with insulin extreme variations in diet are possible, whilst maintaining patients in good health and free of glycosuria. During these years however the incidence of diabetes has shown little change, and there is no proof that we have yet any means of obtaining regeneration of the islet cells of the pancreas. It is probably on these lines, rather than by dietary variations in the control of the disease, that further advance is most likely to come, and there may be pointers in the right direction among the suggestions put forward at the recent Vienna congress (reported on page 1127) over which Prof. Falta presided. Meanwhile it is a notable gain that a greater freedom in food is now known to be possible in diabetes, and if there is any danger in the change of opinion it is only that this freedom may perhaps be carried too far.

◆

MEDICINE AND THE STATE

During the decade preceding the war State medicine in this country developed rapidly from its environmental preoccupations toward functions more directly affecting the individual member of the community. The Notification of Births Act, 1907, brought the health departments into early and direct contact with the mother and her infant; the Education (Administrative Provisions) Act of the same year established school medical inspection and treatment; the Insurance Act, 1911, made a large proportion of the medical profession virtually part-time State officials, and brought into being extensive provision for the tuberculous; while the Mental Deficiency Act, 1913, launched schemes for the care and control of the mentally deficient. The outbreak of war brought an acceleration of this movement, the prevention and treatment of venereal diseases becoming a national and local charge as the result of the Public Health (Venereal Diseases) Regulations, 1916, and great extensions of the local authorities' powers and duties in relation to the welfare of mothers and children resulting from the passage of the Maternity and Child Welfare Act, 1918. Indeed, so rapid were the developments that there began to arise in the minds of private practitioners a good deal of uneasiness about these apparent encroachments on the field of private practice, and this disquiet was only allayed by an admirable report of November, 1928, by Dr. ALFRED COX, medical secretary of the British Medical Association. The tendency of public health legislation was clearly in a direction which required the careful attention of the medical profession in relation both to the welfare of the people and to their own interests, and the advocacy by the Association of extensions of medical benefit before the Royal Commission on National Health Insurance in 1926 was a sign that practitioners had come to realise the inability of persons of the insured class to obtain adequate medical attention by private means. A large measure of socialisation of medicine then seemed imminent. As far back as 1920 the Dawson Report had formulated a scheme for coördinating general practice with hospitals and the existing clinic system of local authorities through a network of primary and secondary health centres linked up with the great teaching hospitals. Ten years later the British Medical Association adopted its "Hospital Policy" and "Proposals for a General Medical Service for the Nation," which were largely an acceptance and an elaboration of the Dawson scheme, and of a widely extended system of medical insurance, regard being taken of the new position which had been created by the passage of the Local Government Act, 1929.

The situation is now very different from what it was two years ago. Excessive claims on sickness benefits and the abnormal burdens falling on unemployment insurance funds have cast doubt upon the soundness of the whole idea of social insurance, both from the economic and the moral standpoint. The international trade slump and our own consequent financial distresses have put out of court in the meantime any extension of services involving subventions which might be a burden on industry, whether directly or through rates and taxes. Moreover, the relative failure to attain that integration of the medical services which the Ministry of Health Act of 1919 and the Local Government Act, 1929, were designed to bring about, centrally in the one case and locally in the other, has revealed the practical obstacles which stand in the way of medical idealism. It is useful therefore to ask whether the ideas have been sound and to observe in what direction other peoples have been going. Before their financial crisis the people of America, faced with a much looser public health organisation than ours, revealing wide variation in provision from State to State and county to county, were beginning to pursue extensive investigations into the machinery of the medical services, of which the White House Conference on Child Health and Protection was a notable example. The most valuable, however, has probably been that instituted in 1928 by the Millbank Memorial Fund and carried out by Sir ARTHUR NEWSHOLME, its scope being the "relation between the private and official practice of medicine, with special reference to the prevention of disease" throughout the civilised world. Sir ARTHUR has related the facts as he collected them in various countries in three volumes of International Studies,[1] and in a book published more recently[2] he gives independently, but, of course, with ample reference to those publications, the conclusions he has arrived at as to the principles which should govern the future progress of State medicine and some guidance past the pitfalls in its way. The earlier volumes were largely the jottings of a peripatetic investigator and serve for reference rather than consecutive reading, but "Medicine and the State" is the ripe fruit of long years of experience as a general practitioner, medical officer of health of a provincial town, and chief medical officer of the local government board, fertilised by the study of foreign methods which he has recently had the opportunity to make.

Apart from the admirable hospital systems of Scandinavian countries (especially those in Denmark) and their relatively complete schemes of social insurance, Sir ARTHUR does not suggest that we have to borrow from other European nations. He finds the medical profession in Germany, France, and Belgium uneasy in their relations to State insurance and the establishment of polyclinics, especially in Eastern Europe, a dangerous substitute for that coöperation of the general practitioners, consultants, hospitals, and the public health service, which is urgently needed and which can only be obtained for a large proportion of the population by means of organisation on some other basis than fee-paying for services rendered. He criticises all existing insurance schemes for their weakness on the preventive side. In his view there can be little further advance in personal hygiene except through the influence of the general practitioner whom he regards as still imperfectly equipped for such work. The first step, he thinks, is to introduce a complete medical examination of every entrant to State insurance and to develop a system of periodical examination of all contributors without waiting for sickness to bring doctor and patient together. As a corollary, more and better teaching of preventive medicine is essential. Effective arrangements are required for making hospital treatment available for those who need it without the intrusion of any other criterion, but it is noted that no country has succeeded in evolving an insurance scheme which is capable of approaching financial capacity to bear this burden upon its funds: Sir ARTHUR retains, on the whole, his faith in the British type of public health service, but he looks forward steadily to the time when the wider association of general practitioners with public medical provision will enable them to do some, at least, of the work now done by assistants in health departments in connexion with the welfare of mothers and children. Several passages in the book seem to imply that he is

doubtful whether a really great advance in the application of the preventive idea can be attained outside of a salaried service; but he is obviously quite aware that no such service can be established until it is welcome to the medical profession. His immediate and practical suggestion is an extension in quality rather than quantity. Against some of the abuses of insurance he suggests technical safeguards derived from the practice of other lands, but he sees no final solution of this problem but in a higher moral outlook. He is firmly a believer in the perfectibility of mankind and quotes with approval in reference to these matters the saying of Senator ELIHU ROOT that "pessimism is criminal weakness."

[2] Medicine and the State. By Sir Arthur Newsholme, K.C.B., M.D., F.R.C.P. London: George Allen and Unwin, Ltd. 1932. Pp. 300. 7s. 6d.

All these things appear to be beyond the realm of practical politics just now. The objects of the Local Government Act have been only partially fulfilled. The outdoor medical service of the poor-law has been little changed. Coöperation between voluntary and council hospitals is not much closer. Indeed, the heralded reform in local government has proved in some places less a break up than a consolidation of the poor-law, and, where steps have been taken to transfer hospitals out of its atmosphere, there is, here and there, an itching to bring them back in the sacred name of economy. But the pendulum swings fast in our time, and we can hardly foresee how soon we may be faced with dangers to medicine of the opposite kind. Sir ARTHUR NEWSHOLME's valuable studies will be indispensable to those who wish to prepare their minds for some of the medico-political problems of the future.

ANNOTATIONS

THE B.B.C. ON MEDICAL PRIVILEGE

BY means of lectures and mock trials the B.B.C. is pursuing the laudable object of acquainting us with the law which every citizen is supposed to know. The latest item in the series of trials, broadcast under the title of "Consider your Verdict," consisted of the closing speeches and the judge's summing-up in imaginary proceedings against a medical practitioner. Listeners were invited to suppose that a doctor had been asked in the witness-box to answer questions in violation of professional confidence and that, instead of refusing to answer, he had given false answers, thereby exposing himself to a prosecution for perjury. In so far as the dramatising of this hypothesis gave publicity to the principle of medical secrecy, and in so far as it explained that the principle exists in the interests of the patients and is therefore for the public benefit, the mock trial was excellent. In so far as it suggested that doctors, *instead of keeping their mouths shut, are ready to* give false answers upon oath, it was less admirable. The hypothetical doctor was supposed to have been asked two questions before the magistrates—had he treated a patient for drug-taking, and had he supplied the patient with dangerous drugs? To both these questions he answered "No." When charged with perjury he admitted that the answers were untrue but, pleading that they were made in accordance with professional etiquette, he contended that they were not "wilfully" false within the meaning of the Perjury Act. Actually, of course, in real life no practitioner would have adopted so inept and so mistaken a line of conduct. He might or might not have declined to answer, according to his personal view of his professional duty. Thereupon the magistrates might or might not have taken serious notice of the refusal. They have not the powers of an assize court to commit a witness for contempt of court. The Summary Jurisdiction Acts enable magistrates to send a witness to gaol for seven days if he refuses to answer proper questions "without offering any just excuse for such refusal." The witness might or might not successfully maintain that medical privilege was a just excuse. But none of these contingencies would give a jury a chance to answer the glib question "should a doctor tell?" The B.B.C., therefore, to bring the doctor's dilemma within the range of the "Consider your Verdict" series, had to drag in the exotic and improbable element of perjury.

The statement that we are all supposed to know the law is not quite accurate. The true legal maxim is that ignorance of the law excuses nobody. A few years ago a witness at the Wandsworth County Court gave yet another version with which many will sympathise. "I know," he said, "that ignorance is no excuse for the law." Whichever of these versions we may prefer, we shall all welcome the efforts of the B.B.C. to instruct us. The medical profession, however, must mildly protest against the broadcasting of a suggestion that perjury is part of the professional duty of a doctor.

TUMOURS OF THE SUPRARENAL MEDULLA

THE tumour of the suprarenal medulla described by Mr. F. W. Law elsewhere in our present issue has two important characteristics—namely, its occurrence in early infancy, and the development of metastases in the cranium. Records of such tumours are now fairly numerous—J. Klein [1] has recently reported a similar case—and so frequently do these characteristics recur, that it may almost be said that multiple tumours of the skull bones and orbits in a child under 2 years indicate either chloroma or malignant tumour of the suprarenal medulla. There are, it must be admitted, cases on record—those of the so-called Pepper type—in which metastases tend to be confined to the abdomen, the liver being their chief site of deposit. Frew found that these were mostly tumours originating in the right suprarenal, and he explained their limitation on the grounds of peculiarities in the lymphatic drainage. A study of the larger number now on record, however, shows that the association of right-sided tumours with limitation to the abdomen does not hold very constantly. Indeed it seems doubtful whether the differentiation of two clinical types, the Pepper type on the one hand, and the Hutchison type with its numerous cranial and other bone metastases on the other hand, is of much value. Quite a number of cases in which liver involvement has predominated, and which might thus pertain to the Pepper group, have shown cranial metastases. It should be remembered that Pepper's collection of cases was made largely with a view to studying congenital tumours of the liver as well as the suprarenals, so that liver involvement was a somewhat prominent feature of his observations. As a general rule it may be taken that the characteristic feature of malignant suprarenal medullary tumours in infants is the tendency to produce far-flung metastases in bone and elsewhere. Subcutaneous nodules for instance, probably similar to those seen in Law's case, were found in a case reported by N. B. Capon[2] as well as in three others which he cited.

---

[1] Amer. Jour. Med. Sci., October, 1932, p. 491.

Views on the histogenesis of these tumours have been revolutionised in the last 20 years. The older observers seem usually to have classified them as sarcomata, and Marchand and Küster were probably the first to demonstrate their histogenic relationship to the sympathetic nervous system, although Virchow had already suggested such a possibility. Nowadays this relationship is generally recognised and accordingly such terms as neuroblastoma and ganglioneuroma have been adopted. A study of their microscopic characters seldom fails to make clear the histogenesis. Most of these tumours, especially the more malignant ones, exhibit the peculiar rosette formations which are characteristic of retinal gliomas, and which, as Shaw Dunn[3] has demonstrated, can be seen in the neuroblastic cells of the suprarenal medulla of the fœtus. Other less malignant ones show unmistakable ganglion cells and nerve-fibres, and Shaw Dunn has traced in an enlightening manner the true interrelationship of the more highly differentiated ganglio-neuromata with the more primitive neuroblastomata. Doubtless some enthusiastic exponent of the newer doctrines on gliomata will sooner or later relegate the latter type to the class of medulloblastomata, if that term is to survive.

These tumours of the suprarenal medulla are interesting because they provide some of the most clearly defined representations of tumours arising from nerve-cells. As Shaw Dunn remarks, they "represent new growths of the most highly specialised cells of the body, cells which apparently never undergo division in normal cases and which are therefore least likely to exhibit neoplastic development."

PRESENTATION TO SIR ST CLAIR THOMSON

PRIOR to the usual scientific business of the Section of Laryngology at the Royal Society of Medicine, on Nov. 4th, a pleasing ceremony was enacted in the form of a presentation, by members of the section, of his portrait in oils to Sir StClair Thomson. It had recently come to the knowledge of certain members of the section that a good portrait was in existence and could be acquired. Mr. Walter Howarth, the retiring president of the section, in making the presentation said that he would not attempt to enumerate the reasons which led to the desire to make the presentation, further than to point out that pre-eminently Sir StClair stood for British laryngology, a specialty which had passed through many vicissitudes before it was recognised as such, and that it must be a source of real gratification to him to realise how great had been his personal share in the efforts for status. Mr. Howarth pointed out that Sir StClair, linguist and traveller, and member of many foreign societies, had secured international friends for the specialty; he had made his house a centre where all men met; and his acts of kindness and help to his colleagues were constant, as many members of the section had experienced. In making the presentation members felt they were doing themselves honour in the act. Sir StClair Thomson's reply was in characteristic vein. Many of his successes, he said, had come to him unsought, so that he felt like a man at the end of the Great War who displayed a long row of medals across his chest, and when asked how he got them replied, "The first one I received by mistake, and I got the others because I had the first." One of his ambitions, he said, had been to earn the esteem and regard of his fellows, and in that he must now believe he had not altogether failed.

SUN-GLARE IN IRAQ

Squadron-Leader P. C. Livingston has made some interesting observations on the effect of sun-glare on the eyes not only of airmen, but of other Europeans employed in various capacities in Iraq.[1] Trouble arises mainly, not from atmospheric glare reflected from the sky but from light reflected from the ground, either directly on to the macula or laterally on to the more peripheral parts of the retina. The possible ways in which the visual function may be affected were studied as regards visual acuity, accommodation (spasm or fatigue), alterations in the field of vision and of the senses for form, light, and colour, spasm or fatigue of convergence and alterations in muscle balance, and finally cerebral fatigue involving loss of power to concentrate as well as many of the defects already mentioned. The importance of these observations will be evident in relation to airmen for whom defect in any of these factors is liable to cause accidents. Those examined were divided into five groups according to their occupation, air pilots forming only one of the groups. Over 100 persons were subjected to the various tests, and as far as was found possible all were given a thorough examination once a month during the period from May, 1930, to November, 1931, each being examined from five to ten times. As to visual acuity, 14 of those tested were found to have fallen below their initial visual standard, and in these the general tendency was always towards recovery in the cool weather. In three cases however the loss persisted. Fatigue of accommodation and also of convergence tended to increase during the hot weather. Nearly all those tested suffered to a greater or less extent in these respects. The power of binocular coördination, tested by the Bishop Harman diaphragm test, was affected prejudicially in most of those tested, and this, too, more in the summer than the winter. The importance of this function is great in relation to effecting a safe landing in an aeroplane. A good deal of attention was paid to the light sense—light minimum and light difference—and a new apparatus is described (the Clement Clarke test) by which these senses can be more accurately tested than by other tests in common use. A reduction in both senses was found to be exceedingly common. The visual fields were also found to be contracted concentrically to some extent in certain cases—between one-half and one-third of those examined. In 13 cases ring or arcuate scotomata were demonstrated. On the other hand no fundus changes due to indirect sun-glare were ever demonstrated with the ophthalmoscope. Nor was there any reason to suspect that the colour of the irides had any relation to the effects of glare. There seems to be no way in which we can differentiate between those who are and those who are not susceptible to the deleterious effects of sun-glare. The presence of chronic conjunctivitis naturally tends to increase susceptibility. The outstanding clinical signs of an acute attack are extreme

doubtful whether a really great advance in the application of the preventive idea can be attained outside of a salaried service; but he is obviously quite aware that no such service can be established until it is welcome to the medical profession. His immediate and practical suggestion is an extension in quality rather than quantity. Against some of the abuses of insurance he suggests technical safeguards derived from the practice of other lands, but he sees no final solution of this problem but in a higher moral outlook. He is firmly a believer in the perfectibility of mankind and quotes with approval in reference to these matters the saying of Senator ELIHU ROOT that "pessimism is criminal weakness."

All these things appear to be beyond the realm of practical politics just now. The objects of the Local Government Act have been only partially fulfilled. The outdoor medical service of the poor-law has been little changed. Coöperation between voluntary and council hospitals is not much closer. Indeed, the heralded reform in local government has proved in some places less a break up than a consolidation of the poor-law, and, where steps have been taken to transfer hospitals out of its atmosphere, there is, here and there, an itching to bring them back in the sacred name of economy. But the pendulum swings fast in our time, and we can hardly foresee how soon we may be faced with dangers to medicine of the opposite kind. Sir Arthur Newsholme's valuable studies will be indispensable to those who wish to prepare their minds for some of the medico-political problems of the future.

ANNOTATIONS

THE B.B.C. ON MEDICAL PRIVILEGE

By means of lectures and mock trials the B.B.C. is pursuing the laudable object of acquainting us with the law which every citizen is supposed to know. The latest item in the series of trials, broadcast under the title of "Consider your Verdict," consisted of the closing speeches and the judge's summing-up in imaginary proceedings against a medical practitioner. Listeners were invited to suppose that a doctor had been asked in the witness-box to answer questions in violation of professional confidence and that, instead of refusing to answer, he had given false answers, thereby exposing himself to a prosecution for perjury. In so far as the dramatising of this hypothesis gave publicity to the principle of medical secrecy, and in so far as it explained that the principle exists in the interests of the patients and is therefore for the public benefit, the mock trial was excellent. In so far as it suggested that doctors, instead of keeping their mouths shut, are ready to give false answers upon oath, it was less admirable.

The hypothetical doctor was supposed to have been asked two questions before the magistrates—had he treated a patient for drug-taking, and had he supplied the patient with dangerous drugs? To both these questions he answered "No." When charged with perjury he admitted that the answers were untrue but, pleading that they were made in accordance with professional etiquette, he contended that they were not "wilfully" false within the meaning of the Perjury Act. Actually, of course, in real life no practitioner would have adopted so inept and so mistaken a line of conduct. He might or might not have declined to answer, according to his personal view of his professional duty. Thereupon the magistrates might or might not have taken serious notice of the refusal. They have not the powers of an assize court to commit a witness for contempt of court. The Summary Jurisdiction Acts enable magistrates to send a witness to gaol for seven days if he refuses to answer proper questions "without offering any just excuse for such refusal." The witness might or might not successfully maintain that medical privilege was a just excuse. But none of these contingencies would give a jury a chance to answer the glib question "should a doctor tell?" The B.B.C., therefore, to bring the doctor's dilemma within the range of the "Consider your Verdict" series, had to drag in the exotic and improbable element of perjury.

The statement that we are all supposed to know the law is not quite accurate. The true legal maxim is that ignorance of the law excuses nobody. A few years ago a witness at the Wandsworth County Court gave yet another version with which many will sympathise. "I know," he said, "that ignorance is no excuse for the law." Whichever of these versions we may prefer, we shall all welcome the efforts of the B.B.C. to instruct us. The medical profession, however, must mildly protest against the broadcasting of a suggestion that perjury is part of the professional duty of a doctor.

TUMOURS OF THE SUPRARENAL MEDULLA

The tumour of the suprarenal medulla described by Mr. F. W. Law elsewhere in our present issue has two important characteristics—namely, its occurrence in early infancy, and the development of metastases in the cranium. Records of such tumours are now fairly numerous—J. Klein [1] has recently reported a similar case—and so frequently do these characteristics recur, that it may almost be said that multiple tumours of the skull bones and orbits in a child under 2 years indicate either chloroma or malignant tumour of the suprarenal medulla. There are, it must be admitted, cases on record—those of the so-called Pepper type—in which metastases tend to be confined to the abdomen, the liver being their chief site of deposit. Frew found that these were mostly tumours originating in the right suprarenal, and he explained their limitation on the grounds of peculiarities in the lymphatic drainage. A study of the larger number now on record, however, shows that the association of right-sided tumours with limitation to the abdomen does not hold very constantly. Indeed it seems doubtful whether the differentiation of two clinical types, the Pepper type on the one hand, and the Hutchison type with its numerous cranial and other bone metastases on the other hand, is of much value. Quite a number of cases in which liver involvement has predominated, and which might thus pertain to the Pepper group, have shown cranial metastases. It should be remembered that Pepper's collection of cases was made largely with a view to studying congenital tumours of the liver as well as the suprarenals, so that liver involvement was a somewhat prominent feature of his observations. As a general rule it that all the butters, English or Antipodean, from cows fed with grass or cod-liver oil had approximately the same value. This result is in conformity with some of the most recent research, which has indicated that vitamin A, when absorbed in great quantity, either in the form of vitamin A or of carotene, though it may be stored in the liver in large amounts, is not transferred to the milk of a lactating mammal in anything like a proportional quantity; there seems to be a maximal value for the vitamin A in milk which is not exceeded however much is ingested. Doubtless all the butters investigated were derived from cows receiving vitamin A in amount sufficient to produce the maximal possible output into the milk.

THE NATURE AND TREATMENT OF ULCUS TROPICUM

NEXT to fevers and fluxes, ulcerations of the skin, in some form or other, are one of the worst scourges of the untutored native. There are ulcers which are easily recognisable as being due to yaws, syphilis, veld sore, or dermal leishmaniasis, but these are not exactly what is meant by tropical ulcer. The lesion known by this name is a sloughing phagadænic condition affecting mainly the legs, and common in most tropical countries, especially those with a hot damp climate. Occasionally this disease assumes epidemic proportions and may sweep forward like a plague. The ulcer commences as a bleb, or bulla, and rapidly breaks down, involving, in serious cases, muscles, tendons, vessels, and nerves, and it may be the periosteum of the bones.

Because of its prevalence and the illness it causes, special attention has been directed towards ulcus tropicum in Central and East Africa, where, indeed, it forms one of the major problems. The patients usually exhibit signs of malnutrition and, as recorded by W. E. McCulloch[1] in 1928, examination of natives in Northern Nigeria showed that those suffering from this condition had a high blood-sugar but a low calcium content, whilst analysis of the native dietary disclosed a marked preponderance of carbohydrate with a deficiency in both protein and salt. It is believed that that lowered resistance of the tissues leads more readily to invasion by pathogenic organisms. These views are more or less supported by the work of M. Hughes[2] and T. R. F. Kerby[3] in Malaya. In our issue of Oct. 22nd Dr. L. J. A. Loewenthal subscribes to the generally accepted view that tropical ulcer is best regarded as a deficiency disease. His observations were made in Uganda, and he considers that the spirochætes and fusiform bacilli so constantly recovered from these lesions are of no significance because they are found in every wound and abrasion of the skin in the tropics. It is noteworthy that in the Bugwere and Bugishu districts of Uganda tropical ulcer is seen almost exclusively among the poorest classes of natives; seldom, if ever, does it appear in a chief's family or amongst the Baganda, who are well-to-do and eat meat twice weekly in addition to their customary diet of milk, unripe bananas, and sweet potatoes.

Treatment with antiseptics and intravenous injections of novarsenobillon having proved disappointing, Loewenthal tried daily intravenous injections of calcium chloride (grs. 15 in 10 c.cm. distilled water). This remedy rapidly brought about the disappearance of the offensive smell and was followed by granulation and healing. The average duration of calcium treatment was 4·8 weeks, whereas the average duration of other forms of treatment was eight months. In our present issue, however, Dr. Clifford James describes an entirely different way of dealing with tropical ulcer which he has successfully used in Choiseul, British Solomon Islands. He has adopted excision and skin-graft of the ulcers, because among the Solomon Islanders it is found that after ordinary cicatrisation the scar rapidly breaks down again. The methods were curettage of the ulcer and application of seed grafts, or cleaning of the ulcer by medical methods, with application of Thiersch or seed grafts to the granulations; or, again, actual excision of the ulcer and immediate or subsequent application of Thiersch or seed grafts. The ideal treatment, according to James, is one which heals a tropical ulcer by replacing it by normal or nearly normal skin. The results proved, in his capable hands, most gratifying; out of a series of 45 cases, all except 4 were completely successful. The question of a dietetic factor amongst these primitive Melanesians is not discussed, but doubtless it is present there as well.

IDIOPATHIC STEATORRHŒA

Samuel Gee in 1888 gave what has proved to be a classical account of the "cœliac affection." Since that time there have been many reports of similar cases masquerading under almost as many names. The result has been confusion and ignorance, and it will be useful to many readers to have the comprehensive review of the literature which has now been made by Dr. Izod Bennett, Dr. Donald Hunter, and Dr. Janet Vaughan.[1] Their paper is, however, more than a review, for it contains the report of a series of cases which have been fully investigated. Their conclusion is that the disease, though probably closely allied to tropical sprue, is not identical with it, as some observers believe. On the other hand, since most cases begin in childhood as typical examples of cœliac disease, there appears to be no justification for the term "non-tropical sprue." The clinical picture is varied. Steatorrhœa and disturbances of calcium metabolism alone are common to the whole group; hence the adoption of the name "idiopathic steatorrhœa." Other features often seen are severe anæmia, cutaneous lesions, infantilism, clubbing of the fingers and toes, megacolon, and a flattened type of blood-sugar curve after the ingestion of glucose. The anæmia may be hypochromic, megalocytic and hyperchromic, or erythroblastic in type. Tetany, gross bony deformities, spontaneous fractures, bone pains, and lens opacities are the outward signs of the disordered calcium metabolism. Histological examination of bone from several cases proves the presence of osteoporosis and osteomalacia. As a rule the serum calcium is low, and calcium-balance estimations show high figures for fæcal and low figures for urinary output. Plasma phosphorus estimations are variable. Estimation of the fat in the stools shows no failure to split fat but an excessive excretion. Treatment is of necessity difficult, and varied in its success. It is often possible to relieve one symptom by appropriate methods without influencing others. The steatorrhœa must be controlled by a low fat diet, while increased intake of calcium and vitamin D may relieve the tetany and the pains due to osteomalacia. The anæmia responds satisfactorily to appropriate therapy. Large doses of

irritability of the conjunctivæ, the vascular suffusion that ensues upon examination, and the profuse lacrymation on exposure to any degree of illumination. There is, however, no development of muco-pus as in conjunctivitis and no blepharitis. Later, as the acute symptoms abate, the chronic ones already noted remain.

As to prophylaxis, it may be taken as proved that the careful use of anti-glare spectacles is an efficient safeguard. The intensity of the visible rays is the main source of trouble and accordingly a moderately smoked glass gives much comfort, but any glass that is unnecessarily dark seems to have a depressing effect. And so, according to Livingston, do yellow and blue glasses. Numerous types of glass have been invented claiming to combat the harmful effects of certain invisible rays by their power to absorb them. As to the ultra-violet rays plane glass reduces them to a certain extent, a greater effect in this respect being obtained by Crookes's glass, Euphos, or others. The absorption of the infra-red rays is probably more important and less easily obtained. Tests with a glass named Infrex are favourably mentioned and so is Crookes's glass, but in Livingston's opinion the ideal balance that will embody adequate reduction of either end of the invisible spectrum with simultaneous optimum translucency for the visible spectrum has not so far been completely realised. Attention should be paid to the frames. The glasses should be large, oval, and directed downwards so as to engage reflected glare. The side-pieces should be dust-proof but not air-proof, and the bulk should be reduced as far as possible. Lastly the functional element often associated with these cases should not be forgotten. For many of them the darkened and silent room is the worst possible environment.

THE MEDICAL CURRICULUM ANALYSED

AT the last meeting of the Section of Medicine of the Royal Academy of Medicine in Ireland, Dr. W. G. Harvey read an interesting paper on that difficult topic, the teaching of special subjects in the medical course. The aim should be, he said, to shape students to be qualified to deal with disease to the safety and satisfaction of the public, and not to produce a body of all-round specialists. He urged that in dealing with any particular new subject which appeared as a candidate for inclusion in the curriculum, the particular reasons for its inclusion should be stated in the face of the difficulties of overcrowding with which the existing course is attended. Speaking as a dermatologist, Dr. Harvey was satisfied that this subject was sufficiently recognised in the ordinary course of training. Dr. R. R. Woods, dealing with instruction in diseases of the ear, nose, and throat, outlined a programme which would certainly raise the average of the students' practical knowledge, but which would require considerable time as well as anxious tuition if the training were to be practical. Dr. E. T. Freeman spoke of the necessity of training medical students thoroughly in respect to pulmonary tuberculosis, and found the facilities usually supplied wanting; while Dr. R. E. Steen emphasised the need for the better teaching of pædiatrics, where he was supported by Dr. W. R. F. Collis, who thought the subject especially badly taught in England. Dr. W. C. MacFetridge found that most practitioners now carried about a modern ophthalmoscope for use in diagnosis, and assumed to that extent that their training as students had enabled them to make practical use in general therapeutics of a difficult piece of special training. The president summed up the position by finding the student under the existing pattern of teaching swamped in detail which precluded the acquisition of a scientific outlook. The debate formed yet another illustration of the discontent with which the medical curriculum is regarded by an increasing number of medical men, and another argument for some general attempt for its revision

VITAMINS IN BUTTER

THE public has been coming more and more to value Australian and New Zealand butters for their flavour and cheapness. Nutritional experts, on their part, have long held that, as the Australasian cows are on pasture all the year round, these butters should, in theory, be well endowed with fat-soluble vitamins. It is interesting to have this opinion confirmed by an investigation carried out over a period of four years by Mr. S. S. Zilva, D.Sc., and his two colleagues, Miss Crawford and Miss Perry, the work being done at the Lister Institute under the auspices of the Medical Research Council and supported by a grant from the Empire Marketing Board.[1] Samples of butter from Australia and New Zealand, deriving from herds of different types, prepared in different ways, in summer and in winter, and kept for different periods were examined biologically for vitamins A and D. Comparable tests were also made on butter from English cows, fed in stall over the winter, on a diet of concentrates and receiving cod-liver oil. Anyone conversant with the conduct of such tests on animals will realise the labour entailed and the difficulty of making the results comparable over a series of years. In their tests for vitamin D the workers were fortunate in employing during their whole inquiry rats of approximately the same sensitiveness to rickets, so that their results are comparable throughout the whole period; for the vitamin-A tests the animal material was less uniform, and a general comparison is not perhaps so safely made.

In the Australian and New Zealand butters it was found that the vitamin content was uninfluenced by the mode of preparation or by the type of herd from which the milk was obtained. The influence of season was studied only with the New Zealand butters. The vitamin-A content, it was found, was the same in winter as in summer—not a surprising result, for the cows were on pasture, unsupplemented, at both seasons. The vitamin-D content, on the other hand, was distinctly lower in the winter butter, a diminution to be correlated with the greater distance of the sun from the zenith at that season; the period of unclouded sunshine was on an average six hours a day in the winter, against nine hours in the summer. Storage at a low temperature, even for two years, caused only a slight diminution of vitamin content, so that the comparatively short period of storage between the making of the butter on the other side of the world and its marketing in England is not to be regarded as having any deleterious influence.

On turning to the English butter from cows receiving cod-liver oil, the results suggest that even with this supplement, the vitamin-D value is not as high as that of New Zealand summer butter, being nearer to that of the New Zealand winter butter. For vitamin A it is noticeable, assuming that a general comparison of all the results is at least roughly valid,

PNEUMOCONIOSIS

BY J. R. TODHUNTER, M.B. CAMB., D.P.H.
TUBERCULOSIS OFFICER, BIRMINGHAM
AND
G. B. DIXON, M.R.C.S. ENG.
CHIEF CLINICAL TUBERCULOSIS OFFICER, BIRMINGHAM;
MEDICAL SUPERINTENDENT, CITY SANATORIUM

OUR object is primarily to direct attention to those types of pneumoconiosis which arise in connexion with the grinding and polishing of metals by artificial abrasives where the work is not included in the schedule of occupations for which compensation can be claimed when disability or death ensues. Often this disease is indistinguishable from silicosis when investigated, apart of course from the information to be derived from the industrial history. It produces disablement similar to that caused by silicosis and is frequently associated with pulmonary tuberculosis; but, notwithstanding this, the patient is not entitled to compensation for disablement, nor do his dependants receive recompense in the event of his death.

Within recent years silicosis has been included amongst the diseases for which affected workers, under certain conditions, may claim compensation either for death or disablement. Under the Workmen's Compensation Act regulations dealing with silicosis were issued in the Metal Grinding Industries (Silicosis) Scheme, 1927, applying to the grinding of metals by means of a grindstone, glazing when carried on in the same room as grinding, and the racing of grindstones. Compensation may be claimed for the death or disablement by silicosis of a worker engaged in an occupation scheduled in the above-mentioned schemes. In the statutory rules and orders which provide compensation the term "silicosis" is confined to disease brought about by the inhalation of silica dust as free silica (SiO_2). The silica dust may be mixed with other dusts but must be chemically free before the term silicosis can be accepted in its legal sense so far as compensation is concerned.

None of the regulations take cognisance of disease arising as a result of grinding or polishing metals with *artificial abrasives*.

PNEUMOCONIOSIS IN NON-SCHEDULED OCCUPATIONS

There are occupations not included in the schedule for compensation in which the employees develop a pulmonary condition which we have found to resemble silicosis clinically, radiographically and pathologically. Because the employments in which these cases occur are not scheduled, those affected cannot claim compensation under the present statutory orders and regulations. This applies to patients we have met suffering from pneumoconiosis arising from the prolonged use of emery in varied forms, from the use of "compo" and the calico mop, and from employments where nothing has been revealed in the industrial history to show that the individual had been engaged at any time in one or other of those scheduled. The following cases of pneumoconiosis are examples.

CASE 1. *Pneumoconiosis indistinguishable from silicosis occurring in a grease-mopper, and associated with pulmonary tuberculosis.*—Man, aged 38, polisher. Notified as pulmonary tuberculosis Jan. 8th, 1931. History of cough and expectoration for 12 months. Lassitude and loss of weight. On admission to the sanatorium there were signs of extensive pulmonary disease, impaired resonance accompanied by râles over the whole of the right lung and the upper half of the left lung, with sputum containing tubercle bacilli. He went downhill rapidly and died. Patient stated that he had worked for 23 years polishing cranks and wheels with calico mop and "compo."

Post-mortem examination revealed extensive tuberculous disease of the right lung, with a large cavity in the upper lobe; the left lung was slightly less affected, but contained many small cavities. In the left lung there were also numerous plaques of fibrous tissue near the surface, and several more deeply situated.

Some specimens were sent for *microscopical examination* to Prof. Haswell Wilson, who reported as follows: "Sections have been prepared from two portions of the lung tissue. The changes are essentially the same in both. The pleura is thickened, and there are a number of fibrotic areas in the lung substance. In both these situations there are numerous granules of pigment; some of these are black in colour, even when in a fine state of subdivision, and are obviously carbon, but the majority show the greenish tinge associated with particles of silica. Endarteritis has occurred, and the centre of the fibrotic area is necrotic. Many of the adjacent air vesicles show chronic catarrhal change, and contain desquamated epithelial cells in which granules of pigment are seen. A few vesicles are involved in the edges of the fibrotic areas and show collapse and degradation of the epithelial cells to the cuboidal type. In places there are foci of acute tuberculosis with catarrh and caseation. The histological picture is that of pneumoconiosis with acute tuberculosis, and is indistinguishable from that seen in silicosis."

CASE 2. *Pneumoconiosis indistinguishable from silicosis and associated with pulmonary tuberculosis.*—Man, aged 50, labourer. Admitted to hospital July 21st, 1930, with six months' history of cough and expectoration, loss of flesh, and debility. Tubercle bacilli present in sputum, impaired resonance upper half both lungs, and scattered râles throughout both lungs. Radiogram showed extensive mottling of both lungs. Patient was transferred to the sanatorium, took his discharge, became worse, was readmitted, and died on Nov. 28th, 1930.

We were unable in this case to obtain any definite history of exposure to silica dust. The man had spent most of his working life as a labourer in various employments. From the age of 16 to 26 he had worked as a turner in the cycle trade. He next spent 12 months as a builder's labourer, demolishing old buildings, followed by nine years' work as a warehouseman. He then spent 15 months as a labourer in a rubber works. During the war he served in the infantry from 1915 to 1919, and from 1919 to 1922 he was engaged on exhumation work in France. After two years' unemployment he got a job as navvy on road work, and continued at this for four years.

Post-mortem examination.—The pleura was densely adherent to the chest wall, over the whole of both lungs. The lungs on section were tough and indiarubber like; pleuræ and interlobar septa were much thickened. Both lungs showed numerous intermingled dark patches of fibrosis and light grey patches of tubercle. The tracheo-bronchial glands were enlarged, and on section almost black, with numerous grey tubercles, and were hard and gritty to the knife.

Portions of the lungs and glands were sent for *microscopical examination* to Prof. Haswell Wilson, who reported as follows: "There is, in my opinion, definite evidence of pneumoconiosis. In addition to the changes associated with the chronic tuberculous process there are areas of fibrosis in which there are abundant granules of pigment. These appear black in the aggregate, but under the high power have the greenish colour which is found with particles of stone. In any case the fibrosis is more extensive than is found in a pure anthracosis."

CASE 3. *Pneumoconiosis indistinguishable from silicosis in an emery-wheel grinder.*—Man, aged 32, notified as pulmonary tuberculosis April 8th, 1931. Tubercle bacilli present in sputum. Radiogram taken on April 29th showed dense infiltration of the upper half of the left lung and scattered mottling of the remainder; fine flocculent mottling over middle third of the right lung. He was admitted to a sanatorium on May 12th and died on Nov. 9th.

This man had served in the army after leaving schoo until he was demobilised in 1919, when he started work in a motor factory. For the past nine years he had worked as a grinder using an emery wheel, which was always run wet, except for the first four or five months after he began this work.

After death portions of the lungs were forwarded to Prof. Haswell Wilson for *histological examination.* His iron should be given in the hypochromic or erythroblastic types and marmite in the hyperchromic type. No constant anatomical lesions, apart from the osteomalacia, have been found at autopsy. The authors conclude that the clinical picture is dependent upon a disturbance of gastro-intestinal function resulting in deficient production, absorption or utilisation of one or more essential factors.

THE PROBLEM OF THE DEAF

THERE are at the present time about 34,000 deaf-and-dumb persons in England and Wales, of whom some 3000 are under 16 years of age. Dr. A. Eichholz, late chief medical inspector to the Board of Education, has made a study of these people during the years 1930 to 1932 which has just been published.[1] In his investigation he has aimed at covering the field of deaf welfare from three points of view—education, social welfare, and industrial conditions. Particularly he has endeavoured to answer the question how far the burden of deafness carries with it a handicap in the attempt to gain a satisfactory mode of life, and to what extent this handicap may be averted by education and training, or by extension of adult welfare. The mere record of employment obtained by school leavers does not, Dr. Eichholz has found, suffice to enable him to draw valid conclusions about the conditions in which the deaf-and-dumb actually live; it has been necessary for this purpose to tap two other sources of information—namely, the extent of poor-law relief and the experience of welfare societies. Happily the number of deaf-and-dumb children is showing a steady decrease year by year, and there were 760 vacancies among some 4700 places provided in certified schools for deaf children. At present the administration of public health is achieving much to arrest child deafness and post-natal deaf-mutism, but Dr. Eichholz does not surmise whether the group of born-deaf can ever be reduced. Generally speaking the deaf-and-dumb suffer little, if at all, from a physical point of view in their capacity to engage in industrial life. Nevertheless, on the social side temperamental conditions due to isolation, misunderstandings in their contacts with other people, certain difficulties in securing and keeping employment, and a general lack of public sympathy tend to throw the deaf-and-dumb together in order to secure the companionship from which they are otherwise debarred. For this reason deaf-mute marriages are part of their normal life, and Dr. Eichholz does not think it practicable to enjoin abstinence from parenthood upon persons who are able to maintain themselves, to manage their own affairs, and to discharge all the other functions of civil life. Temperamental inequalities are, however, reflected in the proportion of deaf-mutes suffering from mental diseases—seven times as great as that of hearing persons, and of deaf-mute inmates of public institutions, also a seven-fold excess. Domiciliary relief, on the other hand, is little higher among deaf-and-dumb persons than in the general population. Based on the data of his exhaustive investigation Dr. Eichholz would like the Ministry of Health to urge on local sanitary authorities closer attention to the early and continuous treatment of infants suffering from ear defects, and the Board of Education to invite local education authorities to improve their detection of defects and to arrange for the supervision of all cases of detected ear defect by practitioners with otological experience. Finally, being of opinion that more precise knowledge about deafness and deaf-mutism is required, he suggests that the Ministry of Health and the Medical Research Council should take steps to institute a study into the age-incidence, causes, and treatment of ear defect.

BABINSKI

THE loss which the French school of neurology has sustained by the death of Joseph François Felix Babinski is of a very special kind. Tall and handsome, of impressive appearance, none came in contact with him who did not fall under the spell of his personality. For a long period he was taken by the foreigner to be most representative of that brilliant galaxy of men who followed in the footsteps of Charcot, were imbued with his spirit of clinical research, and maintained the tradition of which he was the founder. It would be a mistaken idea to imagine that Babinski's pre-eminence was largely due to the association of his name with the extensor plantar reflex, which he was the first to describe, however much the fact tended to popularise him and his work. That discovery doubtless familiarised many with his attainments, but he did a great deal more of equally enduring value. His studies of hysteria and of so-called reflex paralysis were remarkable alike for the candour with which he discarded theories once warmly cherished by himself and for his endeavour to bridge the gap supposed to exist between the organic and the functional sides of neurology. Advances of recent years in the study of the psychoneuroses from the psychological side have tended to throw into the shade other aspects of these disorders, for which a purely psychological approach does not suffice; and Babinski, in his investigation of the phenomena of reflex paralysis, adopted an empirical line of which more will yet be heard. Throughout his life he was a master clinician, less dependent on neuropathology and the laboratory than many of his contemporaries, and convinced that further discoveries would reward those who pursued the same ideal as his own. At the International Medical Congress held in London the year before the war his was the outstanding figure in his own division, and worthily he carried his honours. Though he never succeeded to the Charcot chair in Paris, this in no way detracted from his celebrity. None of Charcot's pupils grappled with both organic and functional problems with the same facility as he; none is surer to be remembered for his accomplishment in the field of neurology.

THE Lloyd Roberts lecture of the Royal College of Physicians of London will be given at the College, Pall Mall East, at 5 P.M. on Tuesday next, Nov. 22nd, by Prof. L. P. Jacks, principal of Manchester College, Oxford. His subject will be the Liberal Education of the Body.

Sir George Newman's Harveian Oration, "The Debt of Preventive Medicine to Harvey and the College of Physicians," has been published by British Periodicals, Ltd., 19, Cursitor-street, London, E.C., price 1s.

INTERNATIONAL SOCIETY FOR MICROBIOLOGY.—The international congress of this society, which was to have taken place in Berlin in 1933, under the presidency of Prof. Hahn, is, owing to existing world conditions, now definitely postponed to 1934.

---

[1] A Study of the Deaf in England and Wales, 1930 to 1932. Being a Report by Dr. A. Eichholz, C.B.E., to the Minister of Health and the President of the Board of Education. H.M. Stationery Office. Pp. 206. 3s.

will suffice for our present purpose to say that one of the ultimate effects of the inhalation of minute particles of silica or siliceous materials is the production of fibrous tissue in the areas of lung affected and, so long as their action is exerted, the formation of fibrous tissue proceeds. This is particularly the case in silicosis. As the fibrotic changes in the lung increase in area and density, the physiological function of the organ is diminished and contraction, with resulting displacement of the parts, takes place, accompanied by the appearance of areas of compensatory emphysema, and in some cases also of bronchiectasis.

The mere existence of silicosis and other forms of pneumoconiosis is obviously a serious matter for those affected, for these conditions cause varying degrees of discomfort and disablement, and occasionally death. Moreover, in many cases, tuberculosis of the lung is superimposed or associated, which adds to the gravity of the condition so far as the maintenance of working capacity and duration of life are concerned.

Middleton [1] has described three conditions found in the lungs of workers employed in the grinding of metals :—

(1) Silicosis, a form of fibrosis primarily the result of the inhalation of fine particles of silica, in the form of fractured crystalline quartz, and with a definite relationship between its causation and the duration of employment in the industries; related also to a high incidence of and mortality from pulmonary tuberculosis; met with especially in the grinders on sandstone.

(2) A fibrosis, which is found as a primary result of the inhalation of minute particles of dust of such substances as emery, and with a definite relationship between its causation and the duration of employment in the industries associated with exposure to such dust in excessive quantities.

(3) A fibrosis, occurring as a secondary result of some other pathological change, arising either (*a*) as a sequela of a chronic bronchitis or other inflammatory change as the result of dust inhalation; or (*b*) as a sequela of some adventitious process not associated with dust inhalation, but due to antecedent or independent disease or injury.

It is therefore recognised that emery dust may give rise to pulmonary fibrosis, though this disability is apparently not scheduled for compensation.

The following Table shows the Registrar-General's returns for the years 1921–23 for the mortality from respiratory diseases among metal polishers, buffers, moppers, and glazers, compared with that among all occupied and retired males :—

Mortality from Respiratory Diseases in Certain Trades

Death-rate per 100,000.	In age-groups—							
	16–	20–	25–	35–	45–	55–	65–	70–
Bronchitis—								
Polishers, &c. ..	—	26	—	26	74	457	1263	2857
Occupied males ..	1	3	6	20	56	191	509	1771
Pneumonia—								
Polishers, &c. ..	68	77	26	183	277	254	253	317
Occupied males ..	21	28	40	72	103	170	276	472
Pulm. tuber.—								
Polishers, &c. ..	68	231	233	404	351	356	758	—
Occupied males ..	69	136	133	160	166	150	114	64

The comparative mortality figure, all occupied and retired males being taken as 1000, is as follows :—

	Occupied males.	Polishers, &c.
Bronchitis	1000	1962
Pneumonia	1000	2026
Pulmonary tuberculosis ..	1000	2124

The mortality from bronchitis shows a marked excess amongst polishers after the age of 50, while that due to pneumonia is excessive among polishers in middle age, 35 to 55. The death-rate from pulmonary tuberculosis shows excess among polishers at all ages from 20 to 70.

PROPHYLAXIS

It is advisable that workers in occupations and processes known to cause pneumoconiosis should be made acquainted with the risks of their employment. The required information might be imparted in the form of short addresses or talks couched in simple terms capable of being understood by them. Welfare workers should be instructed in preventive measures, and might supervise hygienic methods and, where necessary, correct faulty ones among employees. Such a procedure would be difficult at its initiation, but, if persisted in, could not but benefit all concerned.

There is little doubt that many workers are unwilling to use the respirators and helmets provided for their protection when working at some of the scheduled occupations. Their objections are varied, but many ignore precautions from sheer ignorance of the serious damage that may result from their neglect; others hold the view that to use a helmet or a respirator might create an impression amongst their fellow-workers that they were unduly nervous.

It is now agreed that entrants to the employments from which silicosis may arise should be carefully selected after medical examination, but the examination should include a radioscopic or radiographic investigation, preferably the latter. If silicosis and other forms of pneumoconiosis are to be recognised early, at a stage when removal from the causative agent is advisable if total disablement is to be prevented, annual examinations of the workers ought to be compulsory; nor could these examinations be regarded as effective if radiographic investigation were omitted.

It has been the lot of one of us to spend many hours in the coroner's court giving evidence on inquiries into the cause of death of persons, employed in scheduled occupations, who were suspected of having died from silicosis; and we would like to say to those interested in the prevention of pulmonary disease due to the inhalation of trade dusts, who may be possessed of patience and an analytical mind, that such occasions provide valuable opportunity for the furtherance of one's education in the ætiology of the disease. As a result of this experience we have heard that articles too large to be accommodated in sandblasting cabinets with the door closed are sometimes submitted to the blasting process with the door open, which is not good for the blaster. Also where the blaster is paid by piece rates there is a pecuniary advantage, though an accompanying and often unappreciated personal risk, in opening the cabinet to remove the articles subjected to blasting before the resultant dust has completely settled. If the attendant risks arising from these two causes are already met by existing regulations, it is obvious that the workers would receive more adequate protection from their rigorous enforcement; on the other hand, if the regulations do not cover the points we have mentioned, it is in the interests of the worker that they should.

In some factories in Birmingham where sandblasting is undertaken, the use of sand has been discontinued and chilled iron shot are used instead. For some types of work the innovation is said not to give such good results as the older method—a point upon which we do not feel competent to express report was as follows: "Under a low-power magnification the lung tissue is seen to be studded throughout by small nodular masses about 1 mm. in diameter. In places these merge into strands of dense fibrous tissue along the connective tissue septa and in relation to the vessels and bronchi. Towards the base of one lung there is a mass of dense fibrous tissue in which a number of lymphatic glands are embedded. Under a higher magnification these nodules are found to be (1) laminated nodules of fibrous tissue, many of which contain greenish granules in the interstices; and (2) small chronic tubercles with caseation and giant cells. There is a general increase in the connective tissue septa and in the tissues related to the perivascular and peribronchial lymphatics, and in this also numerous greenish granules together with jet black particles of carbon are seen. In the denser areas towards the root of the lung there is much more extensive fibrosis, which has destroyed much of the lung substance. Many air vesicles are embedded in this tissue. These are collapsed and their lining epithelium has reverted to a cubical type of cell. Granules of silica are scattered through this tissue, together with occasional tubercles, and there are some large areas of necrosis in which much polymorphonuclear infiltration has occurred. The glands at the root of the lung are embedded in dense cicatricial fibrous tissue. They show chronic inflammatory hyperplasia with much desquamation of the endothelium of the sinuses. Occasional [illegible] just visible greenish particles are s[illegible] sinuses, but although there is some carbon deposit there is no generalised deposition of silica in the glands and no *fibrosis. A few small tubercles are present in the glands.* The appearances in the lungs are those of diffuse silicosis, very extensive in its distribution, but only producing a limited destruction of the lung tissue, except at the base, where there is extreme fibrosis. In addition, there are numerous chronic tuberculous nodules which, however, from the relative cellularity of the granulation tissue composing them, would appear to be of more recent date than the silicotic nodules."

---

[1] Macklin, E. N., and Middleton, E. N.: Report on the grinding of metals and cleaning of castings, with special reference to the effects of dust inhalation upon the workers. 1923.

CASE 4. *Pneumoconiosis with associated pulmonary tuberculosis occurring in an emery-wheel grinder.*—Man, aged 44, notified as pulmonary tuberculosis on August 6th, 1931. Tubercle bacilli present in sputum. Admitted to sanatorium on August 27th. Radiogram on Sept. 10th showed flocculent mottling uniformly over lower two-thirds of both lungs, suggestive of a pneumoconiosis. On discharge from sanatorium on Nov. 18th physical signs suggested a diffuse fibrosis of both lungs, most marked in the lower two-thirds of right lung and lower third of left lung.

This man had worked as a grinder at a carriage and wagon works for ten years; he stated he had used an emery wheel all the time. He had ceased this work five years ago, and had since worked as a navvy.

CASE 5. *Pneumoconiosis with associated pulmonary tuberculosis after 30 years' exposure to emery dust.*—Man, aged 50, polisher, notified as pulmonary tuberculosis on March 31st, 1930. Examination on April 8th showed dullness and râles over right upper lobe; general condition good; tubercle bacilli present in sputum. Radiogram showed opacity at right apex with a ring shadow just below the clavicle and mottling of the remainder of the upper half of right lung; throughout the rest of the right lung and the whole of the left lung the striæ were much accentuated, with small intermingled opacities.

Since the age of 17 he had worked as a metal polisher in various workshops in Birmingham, always using an emery bob or mop, except for a period of three years about the age of 30, when he had used a plain felt bob which was fed with sand during the polishing process. He stated that he had never worked in the same room in which any sandstone grinding was carried on. Excluding three years' army service (1915–18) he had done 30 years' work as a polisher. Except for a persistent cough since the age of 30, his general health had been good until the autumn of 1929, when he had begun to suffer from dyspnœa and increased cough. He had had to give up work in March, 1930.

Re-examination on Feb. 26th, 1931, showed impaired resonance over the upper half of the right lung and bronchial breath sounds at the right apex, but no râles: chest expansion 1½ inches; weight and general condition maintained. He felt fairly well except for tightness of the chest and dyspnœa on exertion. He had a morning cough with some expectoration and tubercle bacilli were still present in the sputum.

A radiogram showed no change since April 8th, 1930, except for increased fibrosis and density of the infiltration in the right upper lobe.

His satisfactory general progress, and the absence of any material change in the multiple small opacities shown on the radiogram after the lapse of a period of ten months, suggests that the lung condition was one of pneumoconiosis with localised tuberculous disease of the upper part of the right lung, rather than a miliary tuberculosis.

CASE 6. *Pneumoconiosis associated with tuberculosis in an emery-wheel grinder.*—Male, aged 29, a universal grinder, was first examined on April 23rd, 1931. He gave two to three months' history of cough, expectoration, dyspnœa, loss of weight, and debility; there was loss of resonance and râles over the upper half of both lungs, and tubercle bacilli were present in the sputum. Radiographic examination showed dense mottling and cavitation of the upper half of both lungs, and some coarse mottling of the left base. He was admitted to a sanatorium on May 13th and died on Jan. 23rd, 1932.

This man had been employed as a grinder since the age of 14—i.e., for 15 years. During the whole of this time he is said to have worked with the emery wheel.

Prof. Haswell Wilson's report on this patient's lungs is as follows:—

Post-mortem.—"The pleural covering of both lungs is thickened and opaque. The left upper lobe is the seat of a very large chronic tuberculous cavity. The apex of the lower lobe is permeated by solid greyish tissue with darker pigmented areas. Scattered through this there are numerous tubercles of various sizes, and also a number of small cavities, evidently of more recent date than that in the upper lobe. The base of the lung is œdematous and contains a number of caseous tubercles. The right lung shows changes of similar nature and distribution, but rather less extensive than those in the left side. The bronchial glands are deeply pigmented and firm, but not gritty in consistence; a few small tubercles are present.

"*Microscopical section* of nine blocks from different parts *of the lungs and glands have been examined.* The lung substance generally is the seat of patchy fibrosis, and the pleura is much thickened. The fibrous areas in the lungs are all associated with the presence of minute granules which have a definite greenish tinge under the high power and are therefore not carbon. The nodules are dense and hyaline in appearance, and in places there is a suggestion of lamination. The granules are largest and are present in greatest numbers at the periphery of the nodules and in the centre, where in places necrosis is occurring; they are only just visible and appear to be undergoing solution. In some parts of the lung, especially in the apex of the left lower lobe, these fibrotic areas are almost confluent and involve almost the whole of the sections. There is a considerable degree of fibrosis in the perivascular lymphatics. Everywhere there is much catarrh of the vesicles, and there are many phagocytes laden with pigment granules. There is also extensive tuberculosis. With the exception of the large chronic cavity in the left upper lobe, the lesions are all of recent origin, with caseation of the contents of the air vesicles and destruction of their walls. The glands at the root of the lungs contain a few recent tubercles. There is a fair amount of pigmented granules, some of which are carbon, and although there is some fibrosis this is not so definitely related to the granules as it is in the lung substance. I am of opinion that the lungs in this case show the changes of pneumoconiosis associated with localised chronic and widespread acute tuberculous lesions."

It is probable that similar cases pass more or less unnoticed, except perhaps by medical men specially interested in pulmonary industrial diseases. This is unsatisfactory, and regrettable, for two reasons: *it* perpetuates a state of affairs under which the affected individuals fail to obtain compensation and, so far as we are aware, it does nothing to place information concerning their physical or industrial conditions in the hands of those whose care it is to see that workers in dangerous occupations are adequately protected.

If a person becomes disabled because of pneumoconiosis he should be eligible for compensation. The decision whether a trade or process should be included in the schedule entitling disabled workers to compensation ought not necessarily to depend on the fact that the associated dust contains free silica in any given proportion, but rather upon the fact that exposure to the dust produced in that employment can be shown to have caused a condition of pneumoconiosis, giving rise to disablement.

SOME EFFECTS OF THE INHALATION OF SILICA AND OTHER DUSTS

Before the condition recognised pathologically as pneumoconiosis can be produced the particles of dust inhaled must find their way into the alveoli; they are therefore very minute. Without entering into a detailed description of the affected lung, it water-supply was available. The council still insisted that the caravan-dwellers constituted a menace to the health of the neighbourhood. It was alleged that they committed indecent acts on neighbouring properties. At the relation of the rural district council the Attorney-General asked for an injunction which Mr. Justice Bennett granted. The judge said the defendant was liable if he allowed his land to be used in a way which involved interference with his neighbours' convenience. Had he omitted some legal duty? He had put his land to an abnormal use and was liable if the health and comfort of his neighbours thereby suffered. The principle of Fletcher *v.* Rylands was the only rule under which he could be held liable. Some of the caravanners, said the judge, were quite respectable people, but the defendant had attracted others with not so high a standard.

Fletcher *v.* Rylands (1868) is one of the most important decisions alike for the law student and the legal practitioner. Some mill-owners constructed a reservoir. They employed a competent engineer and good workmen. In the course of construction some old mine-shafts were found and carefully filled up. When, however, the reservoir was completed and the water was run in, leakage occurred into the plaintiff's adjacent mines. The mill-owners denied liability, contending that they had made their reservoir with competent construction. It was held, however, that apart from any question of negligence, anyone who brings on to his land anything which, if it should escape, may damage his neighbour, does so at his peril and must compensate his neighbour if damage occurs. Mr. Corke's caravan-dwellers were the *equivalent of Messrs. Rylands' reservoir.* To turn a Bromley brick-field into a caravanners' encampment is an exceptional use of the land.

CONGRESS ON DISORDERS OF DIGESTION AND METABOLISM

(FROM OUR VIENNA CORRESPONDENT)

DURING the first week of October the Deutsche Gesellschaft für Verdauungs- und Stoffwechselkrankheiten met in Vienna under the chairmanship of Prof. Wilhelm Falta. Despite the unfavourable conditions prevailing in Central Europe there was a very large attendance. The society, which was founded in 1914, and has at present nearly 600 members, avoids one-sided specialisation by arranging discussions on "borderland" subjects at its meetings, and thus invites the physiologist, pharmacist, chemist, and pathologist to coöperate with the surgeon and internal physician. This year's meeting was conducted on the same lines as the last meetings. The subjects were presented in three sections; each was introduced by three or four eminent professors, who dealt with it from the standpoint of the pathologist, the surgeon, and the internist, and where necessary the chemist or the pharmacologist also gave an introductory address.

ABSORPTION

The first subject was absorption, enteral and parenteral. Prof. G. Mansfeld (Hungary), speaking as a pharmacologist, referred first to the important part played by the skin, chiefly through electro-chemical changes in the subcutis, which regulate osmosis. He pointed out that many dangerous gases are absorbed more easily by the skin than by the lungs—a fact well known in gas warfare. The respiratory epithelium also absorbs certain gases very quickly, while substances like nicotine and insulin are absorbed by inhalation and rapidly transmitted to the blood stream. As regards the stomach, the remarkable fact had been ascertained that the gastric juice distinctly lowers the velocity of absorption in the stomach itself, thus ensuring complete digestion.

Prof. W. Nonnenbruch (Prague), after reviewing what is known about the mucous membrane of the intestines as an absorbing organ, proceeded to show that irritation (or inflammation) of the walls of the alimentary canal tends to promote and increase the absorption of fat. He pointed out that the function of the villi is an important but not an indispensable factor in absorption, and that the internal secretion of the pancreas can be regarded as affecting fat-absorption no longer. The importance of the spleen in this respect is far greater.

Prof. W. Denk (Vienna) described how absorption takes place through the subcutaneous connective tissue and the peritoneum, how toxic substances are absorbed from occluded or gangrenous portions of the gut, and how extravasates (hæmatoma) are absorbed: the differences of the absorptive power of different sections of the gut were also shown. This factor is important in estimating the extent of absorbing surface that can be resected without injurious consequences. Prof. Denk laid stress on the necessity for further study of the problems presented by normal and pathological absorption.

In the discussion following these reports, several well-known workers presented interesting papers relating to this problem. Amongst them may be mentioned Prof. W. Zweig (Vienna), who has made a special study of the fate of radium emanation (radon) in the body. He estimates that within four hours the entire quantity of the ingested emanation is excreted by expiration through the lungs; the stomach absorbs only a small proportion of it. A paper by Dr. E. Urbach (Vienna) dealt with allergic conditions due to alimentary absorption, and the changes produced thereby in the skin. He has found that treatment with propeptones has given excellent results in many stubborn cases (vasomotor rhinitis).

INSULIN IN DIABETES

The second subject for discussion was the problems of insulin and diabetes mellitus. The experimental side was discussed by Prof. Staub (Bâle). He distinguished between the action of the pancreatic hormone and adrenaline, and put forward a new thesis, based on his experiments, attributing the diabetic condition to a loss of tonus of the parasympathetic system, produced by insulin, which he takes to be a hormone. Dr. Herxheimer (Wiesbaden) explained that the chief feature of the morbid anatomy of diabetes is the diminution of the number of the "islet cells" (Langerhans), their "hardening" and hyalinisation. These islet cells can be regenerated from the pancreatic gland tissue, as shown by Mansfeld, but they only produce the hormone, not the other gland tissue. Operative procedure for the cure of diabetic conditions has already been performed in the United States, but the results are not satisfactory.

The action of insulin was discussed in the report presented by Prof. Falta (Vienna). His wide experience has convinced him that it is a characteristic of real diabetes that small doses of insulin may completely restore the balance of metabolism, whilst other kinds of glycosuria are more resistant to the an opinion. But, viewed from the prophylactic side when dealing with silicosis, there can be no room for doubt that the substitution of metallic shot for sand is a distinct advance and one to be encouraged, and it is gratifying to know that many factory owners have readily adopted it in the interests of their employees.

We hesitate to suggest that pneumoconiosis of every description should be made notifiable, because our experience suggests that if notification is to be successful, it must carry with it treatment, supervision, and some measure of protection for the patients. No practitioner can be expected to notify his patients unless something of benefit to the patient results, but we do think that notification of all forms of pneumoconiosis by the medical officers associated with tuberculosis dispensaries or clinics would reveal a hitherto unsuspected amount of this disease in some of our large industrial areas.

SUMMARY

1. The precautions at present taken to safeguard the class of worker we have discussed appear to be either insufficiently effective or inadequately enforced.
2. The inhalation of dusts from occupations other than those included in the schedules may cause pulmonary fibrosis and produce a condition clinically and pathologically indistinguishable from silicosis.
3. It seems advisable to safeguard those who are employed in grinding and polishing metals with artificial abrasives.
4. The necessity for necropsies on those suspected of pneumoconiosis, when opportunity arises, is obvious. When undertaken by skilled pathologists, information as to the prevalence of this disease would be forthcoming.

Reports upon our pathological specimens were made by Prof. Haswell Wilson, of the University of Birmingham, to whom we express our indebtedness.

MEDICINE AND THE LAW

Surgeon and Patient's Consent

WHEN a specified surgical operation is being performed with the patient's consent, it sometimes happens that some more extensive operation is found necessary. The legal position of the surgeon in these circumstances was discussed by Mr. Musgrave Woodman in his presidential address, summarised in our columns last week. A few days earlier the decision of a French court had dealt with a similar situation. Dr. A had been consulted three years ago by a woman with regard to a swelling in the breast. He diagnosed it as a small tumour which he thought was not malignant; he advised operation. A surgeon removed the tumour and on examination believed the case to be one of cancer. He communicated his belief to the patient's husband who was present; the latter told him to act for the best. Apparently further operation was thereupon carried out. Afterwards, when the patient became aware of the extent of what had been done and when she ascertained the conditions in which her husband had given authority, she sued the surgeon for 200,000 francs damages. Thereupon Dr. A, on his side, complained that his professional reputation was seriously affected; he consequently counterclaimed against the patient's husband for damages to the same amount. The case came before the civil tribunal in 1930. By a procedure which may cause English doctors to envy their French colleagues, the tribunal referred the dispute to a commission of three experts, Prof. Balthazar, Prof. Durieux, and Prof. Duvoir. Before the experts had completed their report the patient died, having undergone a fresh operation in the meantime. Before her death, however, she had made her husband promise to continue the litigation in the name of himself and their children. The experts eventually declared that Dr. A was right in what he did. He did not think the tumour malignant; it was proper not to disturb the patient's mind; it was easy to make a mistake in a diagnosis; many malignant tumours begin as non-malignant. When the husband told the surgeon to act for the best he gave a definite consent; the operation which followed was proper. The patient, being then still under the influence of the anæsthetic, was not in a fit state to make a decision. The authority given by the husband was, it was true, insufficient, because as soon as it was a question of life and death, *le droit naturel* prevailed over the civil code. Ought Dr. A then to have waited till the patient regained conciousness? No; the husband might, perhaps, say that natural emotion impaired his ability to give a decision carrying full legal weight, but the patient returning to consciousness after the operation was in a still less favourable condition to form a decision in a matter of urgency. Not only was Dr. A not at fault; his conduct conformed strictly with the dictates of professional practice and also with the law which recognises cases of urgency.

The French decision is interesting despite the differences of French law and legal procedure, and of the idea of responsibility as between doctor and surgeon. The chief English decision is that of Beatty *v.* Cullingsworth (operation for removal of ovarian cyst). It will be remembered that the patient told the surgeon she was going to be married; "if you find both ovaries diseased, you must remove neither." He assured her he would not remove anything he could help. The right ovary was found diseased and was removed. The left was found affected by the same disease in an early stage; the surgeon removed it, thinking it necessary to save the patient's life. She sued him for negligence; the jury found in favour of the surgeon. This result prevented discussion of the legal position on appeal. According to the summing-up of Hawkins, J., who tried the case, the surgeon had always told the patient that she must give him a free hand. If, said the judge, the jury thought that tacit consent had been given, they must find for the surgeon. This question of consent was, of course, the main fact in dispute.

Caravan-dwellers as a Nuisance

Many local authorities have taken powers by local Act to control and supervise dwellers in caravans and other temporary structures. The Surrey County Council's Act of 1931, is a specially elaborate form of such legislation. There remains also the general law to be enforced as is shown by the case of Attorney General *v.* Corke, decided last July and now available in the law reports. The defendant allowed gipsies and others to settle in his disused brick-field, in the rural district of Bromley. He charged them weekly sums varying from 5*s.* to 10*s.*, and a population of about 240 persons was thus collected. The local authority served notice on the defendant under section 94 of the Public Health Act, requiring abatement of the nuisance. He then provided eight water-closets for the brick-field, for which a sufficient further than the laboratory. Others have become invaluable, such as the sera against plague and cholera. The value of antitetanic serum was demonstrated during the Great War, and Dopter's antimeningococcal serum provided a remedy for a disease hitherto always considered fatal. Vaillard's serum against bacillary dysentery, and the serotherapy of yellow fever, of hæmorrhagic spirochætosis, and of infantile paralysis may be mentioned in passing. Turning from specific to crossed serotherapy, Richet gave as a first example of the latter the treatment of snake-bite with antitetanic serum, introduced by Roux and Calmette. Though such crossed serotherapy may not yet have emerged from the realms of empiricism, it may in Richet's opinion have a great future. The same applies, he thinks, to the treatment of syphilis with sera, and "it is again probable that the last word has not been said of the serum treatment of cancer, which since 1895 has given exceedingly encouraging results"; and he went on to state his conviction "that the investigations undertaken on every side with so much ardour in clearing up the ætiology of this disease will find their application in the preparation of a curative serum."

IRELAND

(FROM OUR OWN CORRESPONDENT)

THE PRESENT METHOD OF MAKING LOCAL APPOINTMENTS

In response to a query from the Irish Medical Committee, the Appointments Commission has made a statement of its present procedure in reference to appointments in the service of local authorities. The procedure is given thus:

> In accordance with Section 6 (3) of the Local Authorities (Officers and Employees) Act, 1926, the Commissioners may recommend one, two, or more persons for appointment to an office to which the Act applies. The Commissioners have recently decided that where a local authority wishes to have some freedom of choice in appointments, they will send it the names of the candidates who have been placed first and second, or, if the local authority so desires, the names of the first three candidates. The names in either case will be arranged in alphabetical order. Accordingly, it is now the practice of the Commissioners to ask each local authority whether it desires to have one, two, or three names submitted to it, and to state in the particulars of appointment issued to prospective candidates whether one, two, or three persons will be recommended to the respective local authorities in connexion with the various posts to be filled.

Up to a few months ago the Commission, with the help of a selection board, selected one candidate in each case, and the local authority had no option but to appoint him. The appointment virtually rested with the Appointments Commission. The selection board, which advised the Commission as to its choice, was guided by a statement of the qualifications and experience of the candidates, and by the impression formed at a personal interview. Now that the final choice rests with the members of the local authority, without any guidance as to the relative merits of the three selected candidates, it is clear that less weight will be laid on qualifications and experience, and more on personal and political and family influence. The quality of the candidates for public appointments had greatly improved in the past few years. It is to be feared that there will be a change in the opposite direction as a result of the change of procedure made by the Appointments Commission.

THE DOCTOR'S DAY

"Come, tell me how you live," I cried,
"And what it is you do!"

II.—COUNTY HEALTH OFFICER

The writer is medical officer to two small county councils, one of which contains a borough with a population of about 43,000. In the other there are two small towns with populations varying from 2000–3000. The total population of the two counties is about 67,000. The work of county medical officer includes that of school medical officer, tuberculosis officer, venereal diseases officer, mental deficiency officer, and inspector of midwives; work does not include environmental hygiene, which is performed by the officers of the urban and rural districts.

I usually wake, he writes, at 6.30 A.M. and read for an hour, but not the platitudes of Dr. Worldly Wiseman, nor the effusions of Dr. Social Uplift; as a good Victorian I prefer that helpful tract, "The Importance of being Earnest" and the essays of the incomparable Max. At 7.20 the postman comes, and I read all my letters and decide on my replies. At 9 I go to my office for a quarter of an hour and dictate letters to my secretary. My postage account amounts to £20 per quarter. At 9.30 I attend three women with gonorrhœa, and a like number of men, at the dispensary in my garden. I give two artificial pneumothorax refills. One or two cases are treated for syphilis. I return to my office, sign my letters, and make arrangements for my next week's work.

A DAY IN THE CAR

I get into my car and take my nurse with me. We drive to the nearest town, where I treat three more cases of syphilis in their own homes by intravenous and intramuscular injection. We go to another house in a village to do an artificial pneumothorax operation, and examine another consumptive in the same house. We then pass on to another village where a boy has recently come home from a special school for defective children. Is he to go back in view of the economy campaign? I find he cannot repeat "round and round the rugged rock the ragged rascal ran." My committee is advised that he should be allowed to return to the special school. We go to another village to examine a boy whose mother has asked that he may be excused from attending a central school. I find the boy is suffering from rheumatism, and that his heart is right out in the mid-axillary line. He is pale, anæmic, and pyrexial. He is advised to stay away from school for a year. We pass on to another village where an artificial pneumothorax refill is undertaken in the patient's home; and to yet another village where we treat a lady with gonorrhœa on her kitchen table, and give her an injection for syphilis on her sofa.

By this time it is 1 P.M. My nurse and I lunch in the car. This takes 20 minutes; then off we go ten miles to inject a boy with congenital syphilis with neokharsivan and bismuth in his own residence. After that we go another ten miles to attend a lady and gentleman, both of whom are suffering from syphilis. The lady was discovered at a school medical inspection with a large gumma in her neck. Her husband showed no signs of disease, but shortly developed epileptic fits and his Wassermann reaction was found to be strongly positive. The children showed no signs of congenital syphilis, and the blood test in all four of them was negative. We pass to the county town where two cases of pulmonary tuberculosis are visited and two cases of syphilis treated in their homes. We go on to another village where we see a case of congenital syphilis which has been under constant treatment for five years. When ingestion of the hormone, unless it is given in very high dosage. These latter cases are, however, often free from sugar for a long time. Degenerative changes in the pancreas are always present in diabetes, whilst changes in other organs (adrenals and hypophysis) are only of a secondary nature. Falta believes that the insulin-resistant cases are due to an increased counteraction of the adrenals; perhaps this hyperfunction may itself in some instances produce diabetes. At present two types of disturbances of sugar-metabolism are distinguished. In one group, the "insular organ" is over-active, and we find super-insulinism; in the other the adrenals act too little. In both instances we find the hypoglycæmic complex of symptoms. Again, there may be atrophy of the insular organ, with hypertrophy of the adrenals. Here we have hyperglycæmia and increase of sugar in the urine. The majority of insulin-resistant patients can be made free from sugar with very high doses of insulin; then the insulin may be almost entirely cut down, and the patients show a permanent tolerance for food.

The subsequent discussion was chiefly devoted to diet in diabetes. The difference of opinion centered around the question: Should diabetics receive food rich in fat or poor in fat? Prof. O. Porges (Vienna) and Dr. Adlersberg, his assistant, advise a diet poor in fat and rich in proteins and carbohydrates. Prof. Noorden, whose experience is probably the most extensive in German countries, now also holds this opinion. Falta prefers more fat in the diet. Russian physicians reported good results obtained in the special diabetic kitchens opened for workmen. Prof. G. Katsch (Greifswald), medical superintendent of a diabetic sanatorium on the Isle of Rügen, described his observations on more than 400 patients, who are under constant supervision. They are given the Porges-Adlersberg diet, with plenty of bread (250 g. per day), and plenty of work. The work has a tendency to lower the sugar-content of the blood, as has often been proved. Similar favourable observations were made in Berlin by Rosenberg in the Western Hospital for Diabetics. This was the most important subject discussed at the Congress, for it may be said to be the crux of the therapeutic problems of the present day. So many papers were read on diabetes in general that they cannot all be mentioned here; but the problem of surgical interference, of heredity, of chemical purity of insulin, dermatological symptoms, and sociological points were all brought forward by competent speakers.

THE LARGE INTESTINE

The third day of the Congress was devoted to the problems of the rectum and sigmoid colon. Prof. R. Maresch (Vienna) discussed the formation of polyps, and maintained that their degeneration into cancers takes place only in 37 per cent. of the cases, while some German authors put it as high as 50 per cent. The X ray diagnosis of diseases of these parts was presented by Dr. Fischer (Berlin), who spoke especially on diverticula. He pointed out that modern methods of examination make it possible to decide by X rays whether the passage in the intestines is impeded by spastic or organic causes, intrinsic or extrinsic factors, of inflammatory or neoplastic nature. Prof. Mayer (Berlin) pointed out that neoplasms of the rectum have been observed in children of 11–13 years of age, and laid stress on the fact that microscopical examination alone is not sufficient to distinguish definitely between a malignant and a benign tumour; each case must be judged on its merits. Gynæcological problems in connexion with pathological conditions of the lower intestinal canal were discussed by Prof. G. A. Wagner (Berlin), who made special reference to the injuries caused by radium application in the vagina or rectum, and advised the use of high-voltage X rays. Dr. Boas (Berlin) read a paper on rectal inflammations and eczema, and advised a diet with no condiments or salt. Prof. Finsterer (Vienna) demonstrated cured cases of rectal new growth operated on under splanchnic anæsthesia some 15–20 years ago. Electrosurgery (coagulation) was strongly advocated by Dr. F. Mandl (Vienna), and "subaqual intestinal lavage" was discussed and advised by Prof. R. von den Velden (Berlin). A very interesting paper on intestinal parasites was read by Dr. Fiebiger, of the Veterinary College, Vienna, and Zweeg and Schindler showed their instruments for deep examination of the rectum and stomach (proctosigmoscope and flexible gastroscope).

PARIS

(FROM OUR OWN CORRESPONDENT)

CENTENARY OF DR. A. GUÉNIOT

On Nov. 8th the weekly meeting of the Academy of Medicine was exclusively devoted to celebrating the centenary of Dr. Alexandre Guéniot. He was present himself, looking like a youthful septuagenarian in his academic robes of violet, green, and gold—a picturesque and distinguished figure with features not unlike those of Sir Clifford Allbutt. The Minister of National Education presided, and the hall and gallery of the Academy were crowded with the élite of the medical profession, and representatives of the Government of France and the municipality of Paris, together with the leaders of the sciences allied to medicine. In recognition of the part he had played in ushering numberless Parisians into the world, he was presented with a medal by the chairman of the Municipal Council. Reference was also made to his presidency of the Academy of Medicine, to his faithful attendances at its meetings even up to the present time, and to a book he had published not so long ago on "How to Live to 100"—a work which doubtless will become a best seller in Paris this month. The Minister of National Education reminded him that since the time of Hippocrates, supposed to have died at the age of 109, there have been many doctors who have led useful and active lives after the age of 100. Dr. Guéniot replied to his many well-wishers in that spirit of gentle banter which was the keynote of the meeting from beginning to end.

PAST, PRESENT, AND FUTURE OF SEROTHERAPY

In a communication to the Academy of Medicine on Oct. 5th Charles Richet, the father of modern serotherapy, indulged in certain personal and impersonal reminiscences, defined its present position, and drew a rough sketch of its future. It was on Nov. 5th, 1888, that Richet and Héricourt made their now famous communication to the Academy of Sciences, and on Dec. 6th, 1890, they gave the first serotherapeutic injection in history at the Hôtel-Dieu. While they pursued their studies in connexion with tuberculosis, and achieved nothing decisive for the time being in this field, Behring and Kitasato made those contributions to the serotherapy of tetanus and diphtheria which proved so brilliantly successful. By 1899 there were no fewer than 45 different therapeutic sera prepared, but several of them never got

CORRESPONDENCE

AUXILIARY TREATMENT OF TOXIC DIPHTHERIA

To the Editor of THE LANCET

SIR,—The work of Schwentker and Noel, quoted by Dr. Woodcock, upon the treatment of the circulatory failure of diphtheria was founded not upon hypothesis but upon very careful pathological and biochemical investigations by themselves and others. The work, which gained the William H. Howell award of the Johns Hopkins University, appeared to me of such great significance that I agreed with my then colleagues in the Birmingham City Hospital—E. C. Benn, E. Hughes, S. Alstead—that it should be repeated and extended. This was done by them under my close observation throughout, and the results, which were published in THE LANCET of Feb. 6th (p. 281), were definitely favourable. At the same time, it must be pointed out that this work required the collaboration of three medical officers working as a team, although it is true that the energies of one of them, Dr. Stanley Alstead, were in part employed in obtaining repeated electrocardiograms from the cases under treatment, and so providing most valuable evidence as to progress. In your last issue (p. 1077) these workers insist, and I agree with them, that when insulin is employed in cases of toxic diphtheria it is of importance that its use should be controlled by blood-sugar estimations. These estimations, which were made throughout by Dr. Hughes, necessitated his being available at all sorts of unlikely times and, in the aggregate, represented many hours of work. In a word, the technique would be difficult or impossible to carry out in small fever hospitals or in general practice.

My observations both in Birmingham and in the diphtheria wards of this hospital have convinced me that the administration of glucose in addition to antitoxin will save the lives of children suffering from hypertoxic diphtheria which would not be saved by antitoxin alone. Hence, assuming these observations to be correct, which from the results of others they appear to be, it becomes important to evolve the simplest possible technique, if this auxiliary treatment is to become of general application. Although I have no experience in the use of the further accessories of iodine, alkalis, and thyroid employed by Dr. Peters, and am not impressed by the hypothesis upon which their use is founded, I agree with him as to the importance of *intravenous* glucose therapy wherever possible. But where intravenous injection is for any reason impossible, then half a loaf is better than no bread, and the oral or subcutaneous route should be resorted to. That part at least of the dose of antitoxin should also be injected intravenously whenever possible in these grave cases and part intramuscularly should go without saying. As to insulin, I think there is little doubt that in some of the cases of the Birmingham series its injection, guided by blood-sugar estimations, turned the scale. On the other hand, within recent months, some striking recoveries have occurred in the wards of this hospital following intravenous antitoxin and glucose to which insulin did not contribute. In my opinion every case of toxic diphtheria should, in addition to an appropriate dose of antitoxin (in part intravenous), also receive glucose at first intravenously and then for next ten days by mouth. Insulin, unless adequate facilities for blood-sugar estimations exist, it is wiser, I think, to omit.—I am, Sir, yours faithfully,

E. H. R. HARRIES,

Nov. 12th. Medical Supt., North-Eastern Hospital, N. 15.

THE ECONOMICS OF TUBERCULOSIS

To the Editor of THE LANCET

SIR,—In your issue of Oct. 29th (p. 956) is a summary of Dr. Jane Walker's address analysing the success of the present-day attempt to control tuberculosis. In an article which appeared in your columns nearly 20 years ago,[1] when I was a tuberculosis officer to the Essex County Council, I analysed the first hundred cases recommended for sanatorium benefit in East Essex and noted how advanced these were before they came under the notice of the tuberculosis officer. The same thing had already struck me when medical superintendent at Benenden—the complaint was in fact familiar at every sanatorium in Great Britain; but my ten years in Essex were enough to show me that the general practitioner was getting more interested in chest work and was thus justifying the existence of tuberculosis officers. During the years which have since elapsed I have not changed my view that sanatorium benefit is a failure, and the reason is clear enough. Let me define a public health "omnibus expert" as a doctor who holds the D.P.H., and who poses as a specialist in tuberculosis and mental deficiency, while he is excellent at his proper job of general public health work and school inspection. I will trace how these omnibus experts came into being. In August, 1912, when Dr. F. G. Bushnell and Dr. N. O. Pitt and myself were appointed tuberculosis officers to Essex, we were, I believe, the first appointments in tuberculosis under the sanatorium benefits section of the N.H.I. Acts. The report of the Astor Commission, under which these appointments were made, covered the situation very carefully. We had to prove that we had held general hospital posts for so long and had been properly trained in tuberculosis work, so that the public as well as the practitioner might have reasonable confidence in us. At that date of course X rays, artificial pneumothorax, phrenic avulsion, and thoracoplasty were practically unknown in this country. When the Local Government Board allowed a local authority to appoint as tuberculosis officer one who did not fulfil the Astor Commission's minimal demands, from that moment did the tuberculosis campaign fail in the areas which had omnibus experts. I shall be told that in these areas to-day we have a chief clinical tuberculosis officer, who is an expert, or a hospital consultant. I agree that they are excellent, but as long as human nature is what it is they will be starved of cases. The result is that sanatoria are full of doubtfully tuberculous cases. The believers in the omnibus experts say that it is waste of money on the same day to let the county M.O.H., the local M.O.H., and the tuberculosis officer visit the same place; but if the tuberculosis officer should diagnose a case as consumption that has not got it, look at the expense to the public and the hardship to the individual. Suppose an omnibus expert is appointed in one of these areas, he is sent to a town of (say) 30,000 inhabitants, he is given a dispensary and waiting-room, but no X rays. On his first visit he may meet in consultation a leading practitioner who has an X ray plant and who may have been a house officer at Brompton 20 years ago. Now two things may happen; he may say he cannot read a film or he may pretend he can. From that moment he is of no further use in the county. I strongly advise return to the able and sensible Astor Commission report; large areas each with a proper first seen this boy was covered with mucous tubercles, but is now a healthy looking and intelligent child; it has taken five years of constant treatment to get his Wassermann reaction negative. One curses the official policy of obscurantism, and passes on to another village where we visit a healthy young woman who was formerly wasted to a shadow with a gummatous ulceration at the back of her pharynx. She has now two healthy babies. Syphilis is preventable and steps should be taken to instruct persons in the means of prevention. This would prevent an unfortunate young woman wasting away till she looked like the victim of an Indian famine, or 14 of my syphilitic patients being nearly blind for months. But the Social Hygiene Council has set its face against instruction of this nature. We now return to headquarters, where we treat more cases of gonorrhœa and syphilis. The day usually ends about 6 P.M.

---

MORE STATIONARY DAYS

Another day is spent on medical inspections and public health work. An excellent attendance of parents at the medical inspections—over 70 per cent. of them come—is secured by writing to each stating the exact time of the child's examination. The parents are asked if the child has suffered from any of the infectious diseases, pneumonia, growing pains, stiff neck, earache, or ear discharge. I also inquire as to the age of beginning to walk and talk, and the method of upbringing adopted in infancy—i.e., breast or bottle, and the use of a dummy teat. During this period the nurse weighs and measures the child, examines the head for cleanliness, tests the child's vision, and hearing by the forced whisper test. The state of the throat—tonsils, adenoids, and goitre—and teeth is then recorded by the medical officer. The heart and lungs are examined by palpation, percussion, and auscultation. The trousers are then lowered in boys, the presence or absence of phimosis and hernia noted, and the position of the testicles ascertained. The stockings are removed and the existence or absence of bunions, flat-feet, and spinal curvature is observed. If the vision is below 6/9, the optic disc is examined, and if the hearing is below 20/20, or if tonsils and adenoids exist, the otoscope is used. The parent, if present, is informed of any defects found and, in addition, after the examination a letter is sent informing the parents of any defects which require treatment. The school nurse visits the home and arranges for the child to attend the ophthalmic, orthopædic, or aural clinics established by the county education committee. In addition, a school dentist visits each school and inspects and treats the children in a horse-drawn caravan. There are no care committees.

As medical inspection can only be undertaken in school hours, and as religious instruction must not be interrupted, only four hours' medical inspection can be managed in any one day. This leaves time to call on any of the nurse-midwives, and to inspect in their homes their bags and registers. Many of the schools have formed milk clubs, and it is important for me to look at the cows and sheds belonging to the farmer who sells the milk. Only the cleanliness of the cows is considered by the medical officer: all the cows in my counties are subjected to a bi-annual examination by veterinary inspectors. The sheds and dairy are examined for cleanliness. I also inspect the cowsheds in company with the veterinary surgeons if samples of milk coming from my counties are discovered by the London or other county councils to contain tubercle bacilli. Between 12 and 2 o'clock I also undertake the inspection of cottages which have been rebuilt under the Housing (Rural Workers) Act —a most useful measure—and the supervision of mental defectives under guardianship or statutory supervision.

In my other county the work is more like that of a medical officer to a medium-sized borough. The mornings are usually devoted to medical inspections, and the afternoons and evenings from 2.30 to 8 o'clock to the treatment of cases of venereal disease and tuberculosis.

WHY DOES THE WORK ATTRACT ME?

There are no half-days. The salary is £1400 a year, with an allowance of £250 for motor-car and also clerical expenditure. The work is attractive for various reasons. In the first place I have no social duties. My wife does not have to call on newcomers; we do not have to entertain. I do not have to go to church, play golf or bridge, or become a Freemason. On the whole I prefer the country to the town. I live in a beautiful village with under 1000 inhabitants. It is mainly agricultural, but recently large cement works have been started, which in no ways disturb the amenities. The house in which I live—the only one available in the county in 1911—and my office accommodation were formerly the county brewery. When I first took the house it was the property of a maltster. The house was in good repair, but was surrounded by brewery buildings in more or less advanced stages of dilapidation. A huge tower overlooked the house, in which all the fowls of the air seemed to congregate. After the war I bought the house, the dilapidated brewery, and an acre and a half of ground for £950. I pulled down the brewery (selling the stone for £150), but retained the offices for the use of my county councils. I laid out lawns and flower-beds where beer had once been brewed. The site of the malting was converted into a sunk garden. Its windows were converted into small alcoves which are filled with flowers. A sun-dial was bought in the Euston-road. The whole, I am told, has a wonderful look of the old-world. A small laboratory, and a wooden building in which patients suffering from tuberculosis and venereal diseases are seen, have been erected on the ground adjoining the office.

I take only two weeks' holiday a year. Larger holidays would bore me. The first week I spend at the British Medical Association, and the rest at Stratford-on-Avon and Malvern. I live in the only county where there is no theatre, so during my last holiday I went to 13 plays in 14 days, chiefly those of the Bard, but also those of Shaw and other authors, produced by Sir Barry Jackson. As I belong to the Royal Society of Medicine and the London Library I never have a dull moment. Sundays are especially delicious. I stay in bed till 11 A.M., reading for about two hours. I then attend to a few patients, chiefly gonorrhœics, do an hour or two's work in the laboratory, prepare abstracts for a medical journal, and then go out for a walk with my dogs for some six miles. Apart from medical work I am kindly allowed to inflict on the local historical societies my hearty admiration of various abnormal persons, such as Catherine II. of Russia, Charles II. of England, and Jeffrey Hudson of Oakham.

Should I like to change my job? On the whole no. In a larger county I should be cut off from clinical work, and in private practice one sees too little of any one disease. You ask, "Are you doing any good?" To this I regretfully answer, "I doubt it," for do I not prolong the life of the syphilitic, the consumptive, and the mental defective? But perhaps this account of an ill-spent life will be of use in preventing others from entering an overcrowded profession.

CONVALESCENT HOME FOR MINERS' FAMILIES.—It is proposed to adapt Berry Hill Hall, Mansfield, a large house surrounded by 80 acres, which has for some years been used as a miners' convalescent home, as a centre for the convalescent treatment of Nottinghamshire miners' wives and children. It is proposed by the local committee of the Miners' Welfare Fund that all the adult colliery workers in the county shall contribute a halfpenny a week towards maintenance and the travelling expenses of patients. There are stated to be more than 200 miners' children in the county suffering from physical disability.

iving a hypodermic of hyoscine hydrobromide r. 1/100. One patient of mine, when she saw her hild, said "is that mine? I thought someone else was aving a baby and I was taking an interest in it." I irst learned the use of hyoscine at St. Andrew's Hospital in 1882. While suggesting its use in midvifery, I can tell you much more of it in cases of nental derangement, other than maniacal cases. I ound gr. 1/100 taken by mouth—it is tasteless in vater—the most useful sedative I knew. It much stonished me from the evidence at the Crippen trial iow very little the medical profession knew of it. Dr. D. J. Leech, of Manchester, asked me to write on t nearly 40 years ago, and I then gave him all my xtensive notes.—I am, Sir, yours faithfully,

New Milton, Hants, Nov. 11th. WILLIAM STANWELL.

DECOMPRESSION IN ENCEPHALITIS LETHARGICA

To the Editor of THE LANCET

SIR,—In Kenya, although we have had a fair number of cases of encephalitis lethargica, I have never known of any to survive. I was therefore justified, when I saw no hope of recovery, in trying anything reasonable on two cases recently under my care. Both were Europeans: one aged 23 and the other 5 years.

The diagnosis was clinically, and according to laboratory findings, as definite as it could be. Both were treated in the ordinary way, by repeated lumbar punctures, until it was quite evident that without continuous drainage of the brain they must die. Subtemporal decompression immediately above the zygoma was done, and the dura entirely removed so that drainage would take place into the depth of the temporal muscle and the fluid be there absorbed. In both, on opening the dura, there was a big flow of water.

After this comparatively simple operation to obtain continuous drainage the worst symptoms immediately disappeared. It took a fortnight in one case and a month in the other before cerebral irritation was quite gone. They are now both well, and without any unpleasant results. One I operated on three years ago, the other one year ago.

I am, Sir, yours faithfully,

Nairobi, Oct. 10th, 1932. R. W. BURKITT.

FUSO-SPIROCHÆTAL DISEASES OF THE LUNGS

To the Editor of THE LANCET

SIR,—If Dr. A. S. Hall will look up the first reference[1] I gave in my paper he will find his question answered very fully by Dr. David T. Smith, of the New York State Hospital for Incipient Pulmonary Tuberculosis, together with a full bibliography, up to that date, of the conditions. Dr. Smith writes:

> "The disease may manifest itself as: (1) pulmonary gangrene; (2) post-operative pulmonary abscess; (3) non-operative pulmonary abscess; (4) abscess secondary to (*a*) aspiration of a foreign body, (*b*) pulmonary neoplasm, or even (*c*) pulmonary tuberculosis; (5) unresolved pneumonia; (6) acute bronchitis; (7) bloody bronchitis; (8) putrid bronchitis; or (9) chronic bronchiectasis. In all these different clinical forms of the disease exactly the same bacteriological flora have been present."

The two acute cases reported by me were obviously cases of post-operative "putrid" lung abscess, the particular type of lung abscess for which the *Bacillus fusiformis* and *Spirochæta vincenti* are believed to be responsible. The chronic cases I believe to correspond to the "bloody" or "putrid bronchitis" of Smith, the "bronchial spirochætosis" of Castellani, Chalmers, O'Farrell, and many others. Mason[2] described "pleural spirochætosis," and Lamb and Paton a case of vegetative endocarditis said to be caused by the same organisms. In one of my cases a chronic syphilitic pulmonary fibrosis may possibly have complicated the condition. Whether a streptococcus or a pneumococcus acts as a sort of "pilot" for the fusiform bacillus and spirochæte in these conditions seems to me a matter of minor importance.

Obviously, many other organisms may be responsible for similar conditions. In another case of mine, met with in a young farmer in 1931, dyspnœa, loss of weight, and sweating were associated with a purulent bronchitis. The sputum contained mycelial threads in large amount. The mycelium was identified by Dr. Gloyne as that of *Penicillium glaucum*, a mould found on decaying fruit, hay, and cattle foodstuffs. After a prolonged course of treatment with arsenical preparations by the mouth, the mycelium disappeared from the sputum after which the condition cleared up completely.

My suggestion is that intravenous arsenical treatment is desirable in all the pulmonary forms of Vincent's disease, in order to dislodge the deeply buried anaerobic spirochætes from their entrenchments. Arsenicals are now being used intravenously even in Vincent's stomatitis.[3]

I am, Sir, yours faithfully,

Buxton, Nov. 7th, 1932. P. HEFFERNAN.

THE INCREASE IN ARSENIC-RESISTANT SYPHILIS

To the Editor of THE LANCET

SIR,—I am gratified to find the thesis of Dr. Drake and Dr. Thomson, that a more resistant form of spironema is making its appearance, supported by Dr. Semon. My reason for bringing this matter before the profession is to have a thorough investigation of the late results of modern syphilotherapy. What I earnestly desire is to get a comparison between these results and what one may call the natural history of late syphilis as demonstrated by Bruusgaard's masterly analysis of César Boeck's patients who had no specific treatment whatever.[4] The venereologist does not come into the inquiry. It demands a cardiologist, a radiologist, a neurologist, and a serologist, working in collaboration with asylum and hospital authorities. After 20 years of arsenical therapy the time appears to me ripe for such an inquiry. Investigation of the immediate results of many thousands of cases, as I understand is being prosecuted by the League of Nations, would have no value in comparison with (say) 1000 cases worked out on the lines of Bruusgaard.

May I assure Colonel Burke that I did not "assume" that syphilis was decreasing in severity before "606" was introduced. As a pupil of Hutchinson, Waren Tay, and others who knew syphilis, I learned that what was described as its "trivial" cutaneous manifestations were the outward and visible signs of a general disease, and in my own clinic that was always my teaching. As students we learned also that there was an ætiological relationship between aneurysm and aortic disease and lues, and although we knew naught of the spironema and had no serologist to make our diagnoses, we knew there was a connexion between it and G.P.I., tabes, and ocular paralyses. As we still tuberculosis specialist, if possible M.D., M.R.C.P. Until then we shall drift along in this hopeless condition, deceiving the public and wasting thousands a year. I am, Sir, yours faithfully,

UNEMPLOYMENT AND RESEARCH

To the Editor of THE LANCET

SIR,—Two and a half days have not been enough to pool half the experience and suggestions on unemployment from the back benches of the House of Commons. But there has been at least one conspicuous omission from the debate—namely, the part science must play in the problem. Mr. Lansbury quoted a recent writer as saying "Science is progressively diminishing the demand for man-power." This is a glaring fallacy. So said the mob that broke up the first spinning-jenny. What could industry do without steam, gas, electricity, fine chemicals, the internal combustion engine—all the products of science? Labour-saving machinery is but a by-product of science. It is to science we must look for fresh developments of individual and corporate life, creating fresh desires and interests in all parts of the world, and increasing the demand for man-power.

The basis of scientific discovery is research, real and not spurious, well guided but free, alike in the basic arts and sciences and in their application to life and industry. In this country we starve research; we appreciate the results, but not the necessary precedents. Honour is given to those who explore mountain-heights, deserts, and polar regions; little to those who explore Nature and substance at our very doors. The encouragement of research—both in pure and applied science—must be one of the most vital, as it is one of the few hopeful, factors in the future expansion of industry and solution of unemployment.

I am, Sir, yours faithfully,

FRANCIS FREMANTLE.

House of Commons, Nov. 9th, 1932.

THE ROYAL MEDICAL BENEVOLENT FUND

To the Editor of THE LANCET

SIR,—I should like to endorse Sir Thomas Barlow's appeal to his fellow practitioners for generosity to the Royal Medical Benevolent Fund. The good work which this Fund has been doing during the last 96 years is well known, but it may not be so well understood that much more urgent assistance could be given if funds were available. Will each member of our profession consider this to be a debt of honour, and one not lightly to be put on one side. I suggest again, as I suggested in your columns three years ago, that when we have benefited by the advice of consulting physicians and surgeons in reference to the health of ourselves, or wives or children, we might well be expected to show our gratitude by sending some help, even if small, to this Fund. There are always piteous cases of doctors who have fallen out of the ranks on account of permanent ill-health, or their widows and children for whom the father has not had a chance to make an adequate provision.

Donations may be sent to the hon. treasurer, R.M.B.F., 11, Chandos-street, London, W.1. I need hardly say that all applications for help are most carefully examined before assistance is given.

I am, Sir, yours faithfully,

Harrogate, Nov. 14th, 1932. JAMES G. MACASKIE.

CHLOROFORM CAPSULES

To the Editor of THE LANCET

SIR,—The administration of chloroform capsules in maternity practice by midwives is perhaps not quite so simple a problem as some may come to believe. These capsules are now being tried by experienced administrators in our most up-to-date clinics in the best of circumstances, and I have no doubt that they will give rise to considerable approval. I shall take as a text for my argument a recent extract from the daily press.

"Mr. ——, —— deputy-coroner, held an inquest yesterday on ——, aged 30, —— wife of a dock labourer, and the mother of nine children, who died in the Maternity Hospital on Friday from asphyxia, while under an anæsthetic for an obstetric examination.

"Miss ——, the matron, said she administered the anæsthetic, which she made up from chloroform and ether, in the presence of Dr. ——, the honorary surgeon. She was a certified midwife, but not a qualified anæsthetist, although she had administered anæsthetics many times. During the examination the patient's face changed colour. Oxygen and other restoratives were applied, but the patient did not revive. A post-mortem was made by Dr. ——, who found that death was due to asphyxia, following the administration of an anæsthetic, accelerated by hæmorrhage and the necessary obstetric procedure which were a predisposing factor by reducing the woman's strength.

"The deputy-coroner, who returned a verdict in accordance with the medical evidence, said it was a matter for serious concern to discover that it was the practice in this hospital for an anæsthetic to be administered by a person who was not fully qualified. He did not attach any blame either to the matron or to Dr. —— for following what was evidently a practice established by their predecessors. In all probability even if a qualified anæsthetist had administered the anæsthetic in this case the same result would have occurred. He thought the anæsthetic was properly and skilfully administered, and that every effort was made to restore the patient. At the same time, in view of modern medicine and the use of anæsthesia as much as possible in confinement cases, he thought the hospital should discontinue the present practice, and arrange for the attendance of a qualified anæsthetist."

This patient, then, died from asphyxia and not from primary cardiac failure. I can imagine the scene. The reflex disturbance in the larynx and respiratory mechanism, set up by manipulations or the stretching of the pelvic floor, the rapidly developing muscular rigidity, the clenched jaws and contracted throat muscles, the swelling and retracted tongue, the deepening cyanosis passing into lividity as the heart fails to cope with the obstructed pulmonary circulation, and finally the few terminal gasps as the respiratory centre gives out. Here is a condition which if once established, especially in a bad light and the poor circumstances which a feather bed offers, might well tax the skill, resource, and presence of mind of an experienced administrator.

I am not antagonistic to the administration of chloroform as an analgesic in obstetrics, for if not the best it is probably the most practical agent for general use at the present time. But will Mr. Rivett and his co-workers be able to arrange with certainty that the use of these capsules will never lead a stout plethoric woman into the unfortunate circumstances which I have described, and should such a train of events develop in the dim light of a cottage bedroom, at which end of the case will the perplexed midwife be the more successful?

I am, Sir, yours faithfully,

London, W., Nov. 12th, 1932. W. HOWARD JONES.

To the Editor of THE LANCET

SIR,—I have been interested lately in discussions on the need for new methods of easing the pains of childbirth. For many years I was in the habit, in cases in which I had previously used chloroform, of nsurance medical practice to final-year medical tudents." The preamble to this and the chairman's tatement made it quite clear (though the resolution tself did not say so) that the payment for these ectures could come from the interest on the capital um of the National Insurance Defence Trust. An mendment was carried limiting the draft from this ource to £150 in any one year, but this amendment n turn was lost as a substantive motion. It was finally esolved that the expense of educating medical tudents in insurance practice should not devolve pon the service itself, but that the attention of he medical schools should be drawn to their esponsibility in providing such instruction.

A PLACE IN THE CURRICULUM

The medical curriculum, we are told, is now under eview by a committee of experts with the idea f eliminating certain matters which are thought o occupy too much of the student's time. It is suggested, for instance, that some of the minute anatomy earnt solely for examination purposes and forgotten within six months, might be eliminated. It is to be hoped that this committee, although in all probability the great majority of its members have not worked under the Acts at all, will consider the necessity of requiring the medical schools to provide some teaching on the regulations of a service into which the majority of their pupils will eventually go. It may perhaps be said without offence that there is room for improvement in the training of the younger men on duty in hospitals in the issue of certificates to any who apply for them. It is unhappily a commonplace remark amongst leaders of approved societies that certificates from hospitals are not worth the paper they are written on. At one time it was a common practice for a batch of blank certificate forms to be signed by the house surgeon or house physician and left in charge of the sister of the ward to fill in details and date. No doubt this practice generally worked without harm, but it had nothing to recommend it from an administrative point of view, and it readily lent itself to fraud. Such certification methods would not be tolerated in the N.H.I. medical service, with the result that the strictness of the rules comes rather as a shock to the newly qualified man entering practice, and leads him to wonder where he has gone wrong when a complaint is made about his certification procedure.

HOSPITAL AND PRACTITIONER

As far as the insurance service is concerned, hospitals are primarily intended either for the obtaining of a second opinion, or for the carrying out of some treatment, operative or otherwise, which the insurance practitioner cannot do himself at home; he, in his turn, is not playing the game if, because a case happens to be somewhat onerous on him in its treatment, he simply sends it off to hospital to save himself the trouble of attending it. It is certainly his duty, when sending up a case to hospital for another opinion, to write to the member of the staff giving some particulars of what is or has been done up to the time of sending it up, and not merely to unload it on the hospital with (or even without) his visiting card. In Scotland and some enlightened areas in this country, a special form is in use for sending up cases to hospital. If this becomes general it should prove a convenience both to practitioner and hospital staff, and help to smooth the pathway of the patient up to the hospital, between its various departments, and back to the practitioner.

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS

The Means Test

ON Wednesday, Nov. 9th, the House of Commons went into committee (Sir D. HERBERT in the chair) on the following resolution in connexion with the Transitional Payments (Determination of Need) Bill:—

> That it is expedient—
>
> (a) To make provision that, in determining under the Unemployment Insurance (National Economy) (No. 2) Order, 1931, questions as to whether the circumstances of applicants for transitional payments are such that, whilst unemployed, they are in need of such payments, the following rules shall be complied with—
>
> (i.) Wounds or disability pensions (as enumerated in Section 16 of the Finance Act, 1919) which are taken into account, shall be treated as if they were reduced by one-half;
>
> (ii.) weekly payments by way of compensation under the enactments relating to workmen's compensation in force in the United Kingdom which are taken into account, shall be treated as if they were reduced by one-half;
>
> (iii.) money and investments treated as capital assets and taken into account shall, in so far as the value of all such money and investments considered in the aggregate does not exceed £25, be disregarded, and, in so far as that value exceeds that amount but does not exceed £300, be treated as equivalent to a weekly income of 1s. for every complete £25;
>
> (iv.) in taking into account the value to any person of any interest in the dwelling-house in which he resides, any sum which might be obtained by him by selling or by borrowing money upon the security of that interest shall be disregarded; and to authorise the expenditure, out of moneys provided by Parliament, of such expenses as may be incurred by reason of the provisions aforesaid; and
>
> (b) to permit the application of the same rules in the granting of outdoor relief under the enactments relating to the poor-law.

Sir H. BETTERTON (Minister of Labour), in moving the resolution, said that its purpose was to enable him to introduce at once a Bill to provide that certain rules should be applied in determining the need of applicants for transitional payment. The resolution also provided that the same rules should be applied in granting outdoor relief. Only those who had exhausted their insurance qualifications, and whose relief was provided wholly by the Exchequer, were affected by the resolution. Under the Order made a year ago it must be assumed that they had exhausted their right after 26 weeks, and he held that that could not be regarded as an ungenerous allowance of time. A man and wife and three children, in 26 weeks, received £38 in benefit, and taking the contributions as 10*d.* per week it would take 18 years before the unemployed person had paid in enough to make up the £38. The claim of the Opposition was that a man who had exhausted his claim on the fund, and then sought relief from the State, should have that relief whatever his means might be, and without any inquiry being made. Such a man was to be privileged as against the insured person because he had exhausted his right, and privileged against the man who applied for poor-law relief because no inquiry was to be made into his means. The Government did not hold that view. The Labour Government had passed the Anomalies Act in order to deal with certain abuses in the system. The present Government were now dealing with abuses which were even more flagrant than those dealt with by the Anomalies Act. There had been discrepancies in administration, and the new Bill founded on this resolution would be directed to a more uniform system of dealing with applicants. The Bill would be limited to three types of resources—disability pensions, workmen's compensation, and savings.

that asylums should retain patients who might quite well be suitably cared for by guardians. District asylums, says the Board, hold land not as a source of profit but in order to provide therapeutic occupation for the patients, and the places of boarded-out patients should be filled by others who have reached a stage at which they would benefit by the work.

All the patients under guardianship were visited last year. Dr. Ferguson Watson reports that their care and supervision attain a remarkably high standard. Most of the guardians have housed patients for many years and their parents and grandparents also undertook this work. Many guardians are skilful at training and improving their patients, some of the most capable and devoted being spinsters, whose motive in taking them is a desire for companionship and a genuine sympathy for those unable to guide their own lives.

The number of patients suffering from general paralysis of the insane at the beginning of this year was 385. Of the 403 patients discharged after treatment for general paralysis during the previous decade 116 had been treated by induced malaria and 287 by other treatment; it is not clear how many of these were also treated by malaria. Ninety-nine, including 40 of the malaria-treated, were discharged as recovered; 110, including 48 malaria-treated, were discharged as relieved, and 194, of whom 28 had been treated with malaria, were discharged as not improved. Sixty-nine of these patients, including 29 malaria-treated patients, have since been readmitted.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED NOV. 5TH, 1932

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 21 (last week 34); scarlet fever, 2283; diphtheria, 1060; enteric fever, 74; acute pneumonia (primary or influenzal), 803; puerperal fever, 28; puerperal pyrexia, 107; cerebro-spinal fever, 24; acute poliomyelitis, 40; acute polio-encephalitis, 5; encephalitis lethargica, 12; continued fever, 2 (Islington, 1; Eastleigh, 1); dysentery, 6; ophthalmia neonatorum, 76. No case of cholera, plague, or typhus fever was notified during the week.

Of the cases of small-pox, 18 (i.e., all except 3) were reported from the County of London, distributed thus among the metropolitan boroughs: Southwark and Stepney each 1, Islington 2, Hackney 4, Poplar 10.

The number of cases in the Infectious Hospitals of the London County Council on Nov. 8th–9th was as follows:—Small-pox, 70 under treatment, 2 under observation (last week 64 and 4 respectively); scarlet fever, 2116; diphtheria, 1775; enteric fever, 19; measles, 225; whooping-cough, 376; puerperal fever, 20 (plus 8 babies); encephalitis lethargica, 231; poliomyelitis, 6; "other diseases," 152. At St. Margaret's Hospital there were 21 babies (plus 7 mothers) with ophthalmia neonatorum.

Deaths.—In 117 great towns, including London, there was no death from small-pox, 1 (0) from enteric fever, 12 (1) from measles, 4 (0) from scarlet fever, 13 (2) from whooping-cough, 25 (4) from diphtheria, 70 (17) from diarrhœa and enteritis under two years, and 41 (8) from influenza. The figures in parentheses are those for London itself.

Watford reported the death from enteric fever. Of the fatal cases of diphtheria, 6 occurred at Hull, 5 at Liverpool, and 3 at Halifax. Four deaths from measles were reported from Birmingham.

The number of stillbirths notified during the week was 233 (corresponding to a rate of 36 per 1000 total births), including 30 in London.

TYPHOID IN YORKSHIRE

The outbreak at Denby Dale being at an end, arrangements are in train for sending 60 convalescents to recruit in the South of England, and attention is concentrating on new sources of drinking water. A water diviner is searching for new springs and in the meantime the village main is being linked up with a reservoir supplying the neighbouring village of Cumberworth.

New cases are still being reported at Malton, the total up to Tuesday night being 230, with 11 deaths. For the past week or so the new infections must be regarded as secondary ones. A group of blood transfusion volunteers has been organised locally. Here as at Denby Dale a distress fund has been opened and has met with generous response.

Dr. L. C. Walker writes to correct certain dates in his account (p. 1085) of the Malton epidemic. The first case came into the poor-law institution on Sept. 23rd (not 21st), and was treated as a typhoid from the 26th.

PANEL AND CONTRACT PRACTICE

Teaching Insurance Practice Methods

AT this season of the year some medical schools arrange for lectures to final-year students on the intricacies of medical practice under the National Health Insurance Act. There may be, attached to teaching hospitals by virtue of some specialty which they practise, a number of insurance practitioners available for this task. But it is one definitely requiring very special qualifications. There are many points arising under the Act that are of the first importance if the practitioner of the future is to avoid the pitfalls which may bring him before the medical service subcommittee, with its associated worry and possible loss of prestige. Last week in this column we touched upon the methods of getting a name removed from one's list of insured persons, and the time when this can be done—matters which are known to few practitioners who are not dealing every day with them. Another conundrum which might be set to would-be lecturers on insurance practice is, who is to pay for the attendance of a nurse called in to give insulin daily to a diabetic patient whom the doctor attending considers incompetent to administer it to him/herself? Or—under what conditions is an insurance practitioner able to charge a bona-fide insured person without illegality, and what is the procedure to be adopted to avoid (quite properly) medical service subcommittee proceedings? If the deans of medical schools who have the interest of students at heart will consult with the secretaries of the local panel committees on this matter, these committees would generally be able and willing to nominate men with a working knowledge of the regulations, who will give chapter and verse for the difficulties which arise frequently in practice. Such lectures would be of material use to students in preventing mistakes in the carrying out of regulations under the Acts.

WHO SHOULD BEAR THE COST?

It will be remembered that this proposal was discussed at some length by the annual panel conference last month, when the discussion turned on the question of cost—it being agreed that there should be some remuneration for such lectures. The Insurance Acts Committee, through its chairman, proposed "that, with the object of preserving the high standard of the N.H.I. medical service, the conference approves the policy of the giving of lectures on uff Cooper replied: I presume the hon. Member to research work in connexion with chemical defence. nly institution is Oxford University. where certain ists carry out experiments for which payment is made Army funds.

MONDAY, NOV. 14TH

Certified Milk Regulations

tain McEwen asked the Minister of Health whether tention had been drawn to the difficulty which the cers of certified milk were faced with by reason of the try's regulation laying down that the date of production be stated on all bottles. so that the afternoon's milk nsaleable until the following day: and. seeing that ading of the regulation by post-dating was increasing, er he would take steps to stop this by amending the ation or otherwise.—Mr. Shakespeare (Parliamentary tary to the Ministry of Health) replied: My right friend is not aware that the practice of post-dating s of certified milk is increasing. and if any case in this is being done is brought to his notice. he will steps to secure compliance with the provisions of the ve Order. My right hon. friend has received some sentations suggesting that the requirement in question d be altered, and these will be considered in conjunction other proposals when an opportunity arises for the dment of the Order.

Maternal Mortality in Stepney

. Potter asked the Minister of Health whether. in of the mortality and morbidity in childbirth in the gh of Stepney, he would call for reports from the cal officers of health as to the advisability of establishing unicipal birth-control clinic in that borough.—Mr espeare replied: No. Sir. Local authorities have no al power to establish birth-control clinics as such. l send my hon. friend a copy of the circulars issued by lepartment on this subject.

TUESDAY, NOV 15TH

Medical Service in Bermuda

ptain Balfour asked the Financial Secretary to the Office the reasons which prevented the coöperation he civil medical staff on the island of Bermuda for g medical facilities to the 444 officers and other ranks which made necessary the services of three Royal Medical Corps officers for this purpose.—Mr. Duff er replied: The reasons may be summarised as follows: he distance between the residences of local civil doctors military stations. and lack of rapid means of conveyance; he fact that the local doctors are fully engaged in their ate practice; and (3) lack of accommodation in civil ital for military patients—necessitating maintenance military hospital. I would remind my hon. and gallant d that the Army medical staff are responsible for the ical care of the wives and families as well as of the ps themselves.

Silicosis

r. David Grenfell asked the Secretary for Mines if he ld give the number of cases of silicosis reported to him each of the British coal fields up to the latest convenient .—Mr. Ernest Brown replied: The following is the rmation asked for: Silicosis is not a notifiable disease the only figures are those of cases in which compensation paid under the Workmen's Compensation Act. The ber of such cases in coal-mines between Feb. 1st. 1929, date on which the Various Industries (Silicosis) Scheme e into operation, and the end of 1931, was 91, including fatal cases. Figures showing the number of cases in h coal-field are only available for 1931, and the distribu- of the 52 cases arising in that year was as follows:—

Area.	Fatal.	Disablement.
South Wales	5	13
Monmouth	5	21
Somerset	1	2
Staffordshire	1	1
Yorkshire	—	2
Lancashire	1	—
	13	39

Ir. David Grenfell asked the Secretary for Mines ether he had considered the compulsory adoption of ering or dust-catching appliances when shot holes were ed in stone by power-driven drilling machines.—Mr. nest Brown replied: The Coal Mines Act requires the of efficient means of preventing the escape of dust from er drills when they are used for drilling in ganister, d sandstone, or other highly siliceous rock. Active ures continue to be taken to ensure effective compliance with this requirement, to ascertain which dusts are injurious to health, and in what circumstances, and to secure the use of practical and effective means of suppressing them.

Mr. David Grenfell asked the Secretary for Mines whether he had received a report on the possible effect of stone-dusting on the health of men working underground: and whether he had had any record of silicosis or anthracosis cases from mines where boring by power-driven drills had not been introduced.—Mr. Ernest Brown replied: The stone-dusting of colliery roadways as an essential protection against coal-dust explosions has been generally enforced by regulation for nearly 12 years past. It has proved remarkably effective and I know of no evidence that the practice has been injurious to health. The suitability of the dust used is constantly watched by the inspectors of mines and steps are taken to prevent the use of unsuitable materials. In coal-mining the development of a case of death or disablement from silicosis is usually a matter of many years. It is very difficult, therefore, to relate the case fully and reliably to the working and medical histories of the worker, and at present the evidence in the very few cases which are not definitely associated with the use of power drills in siliceous rock is not conclusive. The condition of the lungs known as anthracosis is not specifically related to the use of power drills.

Maternity and Child Welfare

Mr. Parkinson asked the Minister of Health what grant would be made towards maternity and child welfare services during the current year: and the amount in the year 1931.—Mr. Shakespeare (Parliamentary Secretary to the Ministry of Health) replied: Under the Local Government Act. 1929. separate grants for maternity and child welfare services, other than the training of midwives and health visitors. ceased to be payable in respect of any year after the financial year 1929–30. The amount of the discontinued grant formerly paid by the Exchequer in respect of these services was included in determining the loss on account of grants under the Act.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

Proby. Surg. Lts. M. G. Stratford and K. Forsythe to be Surg. Lts.

M. G. Ross to be Surg. Lt.

ROYAL ARMY MEDICAL CORPS

Maj. P. M. J. Brett, Res. of Off., relinquishes his appt. under Art. 520 (*b*), Royal Warrant for Pay and Promotion.

The undermentioned to be Majs.: Capts. G. H. Barry, E. J. S. Bonnett. W. Y. Eccott. and C. A. Hutchinson.

R. T. Shipman to be Lt. (on prob.).

TERRITORIAL ARMY

Capt. C. W. F. Greenhill to be Maj.

INDIAN MEDICAL SERVICE

Capt. D. P. Bhargava to be Maj. (Prov.).

Lt. (on prob.) T. D. Ahmad to be Capt. (on prob.).

Lt.-Col. R. H. Bott retires.

Capts. M. S. Segat and C. L. Malhotra relinquish their temp. commns.

ROYAL AIR FORCE

Flying Officer E. K. Pritchard relinquishes his commission on completion of service.

ROYAL AIR FORCE RESERVE

Flight-Lt. R. F. T. Grace is transferred from Class D (ii to Class D (i).

DEATHS IN THE SERVICES

Surg. Capt. Edward Bridges Townsend, R.N., retd., who received his medical education at King's College, and qualified in 1883. died at the R.N. Hospital. Haslar, on Nov. 7th, aged 71. Entering the Royal Navy in 1884 he subsequently served in the battleship *Canopus*. in the Mediterranean. In 1903 he was promoted to fleet-surgeon for conspicuous merit. A year later he was appointed to the cadets training ship *Britannia*. and afterwards served in the Naval College at Dartmouth. A year before the outbreak of the war he became medical officer of the *Vernon*, torpedo school ship, where he served till 1917 when he retired.

National Institute of Industrial Psychology. The Rockefeller Foundation has made a further grant of £5000 towards the research funds of this institute, to be expended in the years 1933–36.

There would be a minimum scheme with discretion to the public assistance committees to go above the minimum if they deemed it desirable to do so according to the merits of the individual cases. Statutory protection would be given to a portion of disability pensions, which proposal conformed to the recommendations of the Royal Commission. The portion to be protected was one-half, but the discretion of the committees would not be interfered with in cases where they deemed it prudent to make larger allowances in cases where medical attention and special diet were involved. The insertion in the Bill of a specific figure of so much a week might do more harm than good, because the public assistance committees might be apt to regard it as a maximum and be disinclined to go beyond it. The question of savings was an extraordinarily difficult matter. What the Government proposed was to disregard savings which did not exceed £25, and where they did not exceed £300 they would be treated as equivalent to a weekly income of 1*s.* for every completed £25. So far as workmen's compensation was concerned, where there were lump sums taken by way of commuted workmen's compensation they were treated as "money or investments."

Mr. GREENWOOD said that the Government had no evidence whatever for their estimate that there would be a saving of £1,000,000. The Bill would not touch the great mass of injustices that have given rise to the growing volume of public indignation in regard to the administration of the needs test. The process was breaking up family life. The resolution did not touch the problem.

After further debate,

Sir E. HILTON YOUNG (Minister of Health) said that there was not a word of truth in the allegation that the inspectors of the Ministry of Health had bullied, badgered, and lectured public assistance committees to reduce the amounts payable to ex-Service men. The purpose of the second part of the resolution was to make it lawful in granting outdoor relief by way of public assistance to observe the same rules as were required by the resolution in relation to transitional payments. They were making in this Bill a change that was temporary, with the intention of its being succeeded by a more comprehensive scheme. In those circumstances it was thought that the changes in public assistance should be as small as possible. The judgment of those best qualified was that the additional charge on local authorities would be very small. He had undertaken to reconsider the basis of the block grant for local authorities in the distressed areas with a view to its revision in the second grant period, and that recommendation was well under way.

Mr. R. S. HUDSON (Parliamentary Secretary to the Ministry of Labour), replying to the suggestion that it might be possible to alter the resolution so as to disregard the whole of disability pensions below 8*s.* or 15*s.*, or some definite figure, said that the Ministry of Health would consider that point. (Cheers.) But it would be impossible to include such an alteration in the present Bill because it would increase the charge. Without in any way committing the Government, he would say that they would bear the point in mind, turn it over, and see when the final Bill, which they hoped to introduce next session, was under discussion, if they could do anything to meet the point. (Cheers.)

Dr. O'DONOVAN said that if the poor in Russia could starve for 15 years for the socialist millenium, he was certain that the English poor could put up with hardships for a couple of years in faith and hope for a better England. (Cheers.)

The resolution was carried by 267 votes to 43—majority, 224.

On the following day the resolution was agreed to on Report, and the Bill was brought in and read a first time.

The Royal Assent

In the House of Lords on Nov. 15th, the Royal Assent was given to the Edinburgh Royal Maternity and Simpson Memorial Hospital Order Confirmation Bill and the Ottawa Agreements Bill.

HOUSE OF COMMONS

THURSDAY, NOV. 10TH

Black-listed Schools

Sir WILLIAM JENKINS asked the Parliamentary Secretary to the Board of Education the number of black-listed schools demolished in 1930, 1931, and up to Sept. 30th, 1932, and the expenditure incurred upon rebuilding such schools, giving particulars for elementary and secondary separately, and the figures for England and Wales separately.—Mr. HERWALD RAMSBOTHAM replied: The following numbers of public elementary schools previously on the Board's "black list" have been closed or replaced:—

Year ending		England.	Wales.
Sept. 30th, 1930	.. ..	61	5
" " 1931	.. ..	42	5
" " 1932	.. ..	52	3

The Board have not compiled any "black list" of secondary schools.

As regards the second part of the question, I am afraid tha it is not possible to analyse the total expenditure incurred on new schools so as to show how much is directly referabl to the replacement of unsatisfactory buildings, as schoo which serve this purpose frequently serve at the same tim to meet other needs, such as increases in population or th improvement of educational facilities.

Sir WILLIAM JENKINS asked the Parliamentary Secreta to the Board of Education what was the number o elementary schools condemned through insanitary an other conditions and placed on the black list on Dec. 30th 1930, Dec. 30th, 1931, and the number on Sept. 30th 1932, or the latest available date; and the number o secondary schools for the same dates and give separat figures for England and Wales.—Mr. HERWALD RAMSBOTH replied: The total numbers of public elementary schoo included on the Board's "black list" were as follows:—

Year ending		England.	Wales.
Sept. 30th, 1930	.. ..	1531	184
" " 1931	.. ..	1381	169
" " 1932	.. ..	1264	158

No schools were added to the list during these years. Th Board have not compiled any "black list" of seconda schools.

Medical Herbalists and Registration

Mr. GORDON MACDONALD asked the Minister of Healt for what purpose he sent the letter he received from th National Association of Medical Herbalists of Great Britain Limited, on April 26th, 1932, to the General Medical Council —Sir E. HILTON YOUNG replied: A copy of the letter wa sent to the Registrar of the General Medical Council b my direction for the information of the Council, becaus the letter put forward a claim by the Committee of th National Association for registration as a teaching an practising body. No request was made or indication give that it was desired that the letter should be regarded a confidential.

The Post-graduate Medical School

Sir ERNEST GRAHAM-LITTLE asked the Minister of Healt whether, in view of the present need of retrenchmen exemplified by the cuts made and contemplated in eve department of public expenditure, and in view of the develo ment since the Athlone Committee reported of numerou agencies for supplying post-graduate teaching at th constituent medical schools of the London Universit it was proposed to proceed with the foundation of the post graduate medical school at Hammersmith; and, if so, wha was the amount of the contribution to be made by th Exchequer.—Sir E. HILTON YOUNG replied: The answe to the first part of the question is in the affirmative. A regards the second part, the maximum of the Excheque grant for the building and equipment of the school wi be £100,000.

Chemical Warfare

Mr. THOMAS WILLIAMS asked the Financial Secretary t the War Office the names of all universities or other edu tional institutions or private research establishments t which grants were given for chemical research work.

n Mary's House "

name has been given to a large house at Fleet, ire. which has been purchased as a home for retired s of Queen Alexandra's Imperial Military Nursing It is hoped that the necessary alterations will be ed in time to allow of the house being occupied pring of next year.

adcast Demonstration

)ec. 2nd Dr. Leo Jacobsohn will give a wireless on cardiac auscultation. In connexion therewith l heart-sounds will be broadcast via the German Königswusterhausen. Medical listeners are asked rt to the Kaiserin Friedrich-Haus, Robert Koch-, Berlin NW 7, on the results of the reception.

ı Health Resorts Association

naugural luncheon of the British Health Resorts tion, Ltd., will be held at the Ritz Hotel, Piccadilly, , W., at 1 for 1.15 P.M. on Tuesday, Nov. 22nd. eston, chairman of the association, will preside, and ıcipal speakers will be Sir Hilton Young, Minister of , Sir Thomas Horder, Lieut.-Colonel R. H. Elliot, ., and Dr. Fortescue Fox. Tickets may be had from secretary of the association, 28, Portland-place, W.1.

y of Apothecaries of London

ecil Wall, the new Master, presiding over a Livery on Tuesday last, Nov. 15th, said that within three the society would celebrate the 300th anniversary irst meeting in the present hall. The general prac- of to-day was the direct lineal descendant of the ary of the seventeenth century. It was a curious of the Act of 1815 that it selected a city company rol the development of general practice, but universal had been accorded to the society's work, and it ced the medical schools of the country into activity. difying its requirements from candidates the society iven a coach-and-four through the apprenticeship , and in 1834 it was able to demand that every should spend three years in a medical school, ng 18 months in hospital. Sir George Makins, ıg as senior liveryman, mentioned that it was rs since he was apprenticed to a member of the , taking his preliminary examination not long after- The society, he said, had always done its best to e medicine, not only by improving education but also h scholarships for research. Sir William Willcox, warden, in proposing the toast of the Medical Schools, at everything was in the melting-pot—economically What was the future of the voluntary future of the medical curriculum? The it should have a voice in the deliberations ed the curriculum, but he was sure that ans of the medical schools should play an important deciding that future. Dr. C. M. Wilson, dean of ry's Hospital medical school, in reply, said that in rds of Dr. Johnson, "there are some subjects from the mind naturally retires"—and one of them was edical curriculum. It had been debated since the f the Greeks, and he feared the solution of the problem not come to the present company at a time when all the blood in their bodies was in the splanchnic . All had their views and remedies. It should be in mind, however, in criticising examinations, that if ere abolished the process of signing-up would have made so strict that it might become a persecution. Vakelin Barratt, senior warden, in proposing the of the Visitors, spoke of the society's continuing pecial interest in materia medica, midwifery, and es of children. Colonel Norman King, registrar of eneral Medical Council, who replied for the guests, hat the Act of 1858 was an advance, because it made ractitioner qualify in all three branches of medical and he could not help thinking that any step which d a partial qualification would be retrograde. The il had no power to lay down rules concerning the al curriculum; its function was to inquire, to suggest, report, and he believed that the way in which it cir- d information about what was being done by the various ng bodies was of great value to many of them. It red to him as a layman that the thing to be sought ot to turn out a specialist but a general practitioner. so doing the curriculum could be lightened it would good thing, and if it were possible to include six ths' apprenticeship to a general practitioner, he thought ould be a great advantage.

mong those present at the dinner were the deans of nedical schools of Guy's Hospital (Prof. T. B. Johnston), tminster (Sir Stanley Woodwark), St. Thomas's (Prof. . Dudgeon), Middlesex (Dr. Izod Bennett), the London . William Wright), and Charing Cross (Mr. Eric Crook).

Royal Society of Medicine

Section of Laryngology.—The first award of the Logan Turner prize will be made in June, 1934. The subject is: To investigate the part played by allergy or sensitisation as a factor in predisposing the mucous membrane of the nasal fossæ and of the paranasal air sinuses to infection, and its bearing upon the treatment of disease of these cavities. Papers should be sent in to the hon. secretary of the Section at 1, Wimpole-street, London, W.

Bacteriological Standards for Milk and Ice-cream

A joint meeting of the metropolitan branch of the Society of Medical Officers of Health and the food group of the Society of Chemical Industry will be held at 5.30 P.M. on Friday, Nov. 25th, at the London School of Hygiene and Tropical Medicine, Keppel-street, W.C. Prof. W. W. Jameson will take the chair, and a discussion on Bacteriological Standards for Milk and Ice-cream will be opened by Dr. Vynne Borland, medical officer of health for Bethnal Green, Prof. G. S. Wilson, of the London School of Hygiene, Mr. E. B. Anderson, of United Dairies, Ltd., and Mr. D. H. Clayson, of J. Lyons and Co., Ltd.

Nurses' Home at Limerick

A wing in reinforced concrete has been added to Limerick county infirmary as a nurses' home. The cost has been defrayed by a grant from the hospital sweepstake funds. Limerick firms have made the whole of the furniture. Every room has a fireplace as well as central heating. The floor vacated by the nurses is to be made into a ward of 20 or more beds, and the Hospitals Trust is being asked to grant more money to enable the institution to be extensively improved.

North Staffordshire Orthopædic Hospital

The Duchess of Portland last week opened a new open-air pavilion of this hospital at Hartshill, Stoke-on-Trent. There are two wards, one each for boys and girls (50 patients), which have cost £7000. The walls are adorned with representations of children's fairy tales and rhymes. The warming is by ceiling radiators. The annual report records that 209 new cases were admitted and 864 out-patients treated—a record number. The average weekly cost per in-patient was £2 14*s.* 2½*d.*—a small increase. The old out-patient block has been adapted as workshops for the making of splints and other appliances.

British Empire Cancer Campaign

Sir John Bland-Sutton presided at the quarterly meeting of the Grand Council of this campaign held in London on Nov. 14th. The following grants, totalling £14,100, were made in furtherance of cancer research: £5400 to the Middlesex Hospital; £2700 to the Cancer Hospital (Free); £2250 to St. Bartholomew's Hospital; £1150 to the Mount Vernon Hospital; £690 to the Marie Curie Hospital; £585 to St. Mark's Hospital; £550 to Mr. I. Hieger, working at the Cancer Hospital; £400 to the Westminster Hospital; £350 to the Medical Research Council, towards the maintenance of the radon centre at the Middlesex Hospital; and £25 to Dr. E. K. Dawson, at Edinburgh.

Mr. Cecil Rowntree is to be the representative of the University of Sydney cancer research committee on the Council, in place of Sir Granville Ryrie.

Hospital Extensions

During the last week or two extensions and improvements to several provincial hospitals have been opened. The most important of them is the Walton Hospital of the corporation of Liverpool (2021 beds), where a new theatre was opened last week by the Lord Mayor, Mr. A. Gates, who stated that the hospital is the largest in the country. The theatre is named after Miss Agnes Jones, who laid the foundation of poor-law nursing in the predecessor of the present institution in 1865. The work she did there is commemorated by a statue in the hospital chapel and by a window in Liverpool Cathedral, in which the centenary of her birth was marked by a service on Sunday last. The hospital deals with 16,000 patients a year, and there are annually between 2000 and 3000 major operations.—Also last week a new male wing of Southport Convalescent Hospital was opened by Princess Blücher.—Sir Hubert Bond has opened an enlargement of Berkeley Hospital, Gloucestershire, which includes one public and two paying wards, a theatre, and accommodation for nurses. The cost has exceeded £2200.—Miss L. R. Gilchrist recently formally opened a new out-patient's department at Tynemouth Victoria Jubilee Infirmary. The building has cost £16,500, the proceeds of a legacy from the late Mrs. Wilson of Easby House, North Shields, and is a memorial to her mother, brother, brother-in-law, and sister-in-law. The building includes two large massage rooms, a theatre, a laboratory, and the usual accessories. The warming is by the panel system.

MEDICAL NEWS

University of Oxford

The following have been appointed or reappointed examiners:—

Anatomy: Prof. J. E. S. Frazer. *Physiology*: Dr. C. G. Douglas, F.R.S. *Materia medica*: Dr. K. J. Franklin. *Pathology*: Dr. E. W. Ainley Walker. *Forensic medicine and public health*: Dr. J. F. Taylor. *Medicine*: Dr. C. M. Hinds Howell. *Surgery*: Prof. G. E. Gask. *Midwifery*: Mr. A. J. McNair and Mr. Wilfred Shaw.

Pembroke College.—The Theodore Williams medical scholarship, of £100 a year for four or five years, will be awarded next spring. An examination will be held on Feb. 21st, and particulars may be had from the senior tutor of the college.

University of Cambridge

Sir Charles Sherrington, O.M., Waynflete professor of physiology in the University of Oxford, has been appointed Bede lecturer for 1933.

University of London

Five lectures on Bacteria in Nature will be given by Dr. F. W. Twort, F.R.S., professor of bacteriology in the University, at the London School of Hygiene and Tropical Medicine, Keppel-street, W.C., at 5 P.M. on Dec. 1st, 2nd, 5th, 6th, and 7th.

Two lectures on Sinanthropus will be given at University College, Gower-street, London, W.C., at 5.30 P.M., on Friday, Dec. 9th, and Monday, the 12th, by Dr. Davidson Black, professor of anatomy in the Peiping Union Medical College, China.

Royal College of Surgeons of England

An ordinary meeting of the council was held on Nov. 10th, with Sir Holburt Waring, the president, in the chair.

Diplomas of membership were granted to the candidates whose names appeared in our issue of Nov. 5th (p. 1031) as recipients of the L.R.C.P. (with the exception of H. F. Moseley).

Diplomas in public health were granted, jointly with the Royal College of Physicians, to candidates whose names appeared on the same page. A diploma in gynæcology and obstetrics was granted, jointly with the College of Physicians, to Dr. Albert Leslie Watson, of the University of Sydney.

Mr. Gerard Sutherland Irvine, late of Epsom College, was nominated the fortieth Jenks scholar. Sir Cuthbert Wallace was elected a member of the committee of management of the Conjoint Examining Board, in the place of Mr. F. J. Steward.

Psycho-analysis in Medicine

At a meeting of the Paddington Medical Society on Nov. 8th, Dr. Ernest Jones spoke on the Significance of Psycho-analysis in Modern Medicine. It enlarged the field of medicine, he said, in two ways. It, for the first time, gave physicians the ability to understand and cope with many conditions in whose presence they had previously been helpless, and it had extended the field of therapeutics to other conditions, such as marital incompatibility, which had previously not belonged to it. He discussed three ways in which physical disease produced a mental situation which tended to evoke any neurotic elements present, through (1) frustration, (2) fear, and (3) suffering. The stress laid by psycho-analysis on the dynamic factors in disease was in accord, he said, with the functional attitude in modern medicine, just as the stress it laid on the instinctual origin of mental conflict was in accord with biological principles.

Fellowship of Medicine and Post-Graduate Medical Association

There will be an afternoon course in infants' diseases at the Infants Hospital, Vincent-square, S.W., from Nov. 28th to Dec. 10th. A course in dermatology will be given at the Blackfriars Skin Hospital from Nov. 28th to Dec. 10th. The course will consist of instruction in the out-patient department every afternoon from 2.30 P.M. Special demonstrations of interesting cases will be given on Tuesday, Nov. 29th and Tuesday, Dec. 6th. Two demonstrations of medical ophthalmology will be given at the Royal Westminster Ophthalmic Hospital, Broad-street, W.C., as follows: Wednesday, Dec. 7th, at 5 P.M., Mr. G. G. Penman, demonstration of fundi of medical interest; Thursday, Dec. 8th, at 8.30 P.M., Mr. C. L. Gimblett, Some Points in Medical Ophthalmology (illustrated by epidiascope). A panel of teachers is available daily for personal tuition in almost all branches of medicine and surgery; arrangement for attendance at these clinics must be made through the Secretary of the Fellowship, at 1, Wimpole-street, London, W., from whom all particulars may be had.

Addenbrooke's Hospital, Cambridge

Sir Humphry Rolleston will open the new Douty clinic at this hospital, at 3 P.M. on Friday, Nov. 25th

Royal Institute of Public Health

The next annual congress of this institute will be at Eastbourne from May 30th to June 4th, 1933. Leverhulme will preside.

L. *councillors (in addition to the above)*: Mr. G. H. representative on the General Medical Council (ex Dr. John F. Fergus, Dr. John Henderson, Dr. A Kelly, Dr. J. Souttar M'Kendrick, Mr. W. F Mackenzie, Mr. John Patrick, Mr. William J. Mr. John Rowan, Prof. Archibald Young, and Young.

Imperial Cancer Research Fund: Annual

The thirtieth annual report records the app Sir Percy Sargent as joint treasurer with Sir George The fund has received a donation of £20,000 to "Miss Elizabeth Wills Allen Memorial Fellowship A. F. Watson, of Sheffield, has been appointed a of the scientific staff as from Sept. 1st, and it h decided to make a grant of £250 per annum to Dr. Todd, of Bristol, towards his laboratory expense report of the director, Dr. J. A. Murray, F.R.S., the researches published in the tenth scientific which has already been reviewed in our colum publications from the laboratory during the issued in this report, include two papers by Prof. R. of New York, and Mr. R. J. Ludford, D.Sc., rec liminary observations on the micro-dissection and injection of normal and cancer cells grown in vitro observations demonstrate the close physico-chem larity of cancer cells to their normal prototypes. Cramer's survey on the Comparative Study of published in the *Cancer Review*, 1932, vii., 241, is as providing a valuable reminder of the pr since the fund was inaugurated 30 years ago, and confirmation of the views advanced at that time importance of the occurrence of cancer in wild and ticated animals for the statement and study of the problem. Dr. H. G. Crabtree has contributed to report a critical essay on the metabolism of the cell, dealing mainly with the results of the which have arisen out of the new lines of inquiry by the work of Warburg.

The executive committee have reluctantly Frederic Hallett's resignation of the post of secre account of his continued ill-health. They appreciation of the way he has guided the policy fund during its 30 years of existence, and believe success and reputation of the fund must be largely to his devotion. In recognition of his invaluable have granted him a pension, and, with the consent president, the Duke of Bedford, Sir Frederic has been a vice-president of the fund.

Medical Diary

SOCIETIES

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

Tuesday, Nov. 22nd.—5 P.M., Medicine. Discussion: The Pathogeny of Nephritis and its Bearing on Treatment. Opener: Prof. O. L. V. de Wesselow. Followed by Dr. J. C. Spence and Dr. T. Izod Bennett.

Wednesday.—5 P.M., Comparative Medicine. Discussion: Heredity as a Factor in Animal Disease. Openers: Prof. F. A. E. Crew and Mr. W. C. Miller.

Thursday.—7.45 P.M., Neurology. Clinical meeting at the out-patient department of the West End Hospital for Nervous Diseases, 73, Welbeck-street, W. 8.30 P.M., Urology. Clinico-pathological meeting. Cases and specimens: Mr. A. E. Roche: 1. Congenital Solitary Kidney. Mr. S. MacDonald: 2. Myoma of Bladder. 3. Ureteric Calculus showing Spontaneous Fracture. 4. Tuberculous Kidney. Mr. J. G. Yates Bell: 5. Total Cystectomy for Papilloma. Mr. H. W. S. Wright: 6. Hypernephroma with no Local Symptoms, with a short description of [illegible] mino-thoracic Exposure of the Kidney. 7. Carcinoma of the Urethra. Mr. E. W. Riches: 8. Prostatic Ducts shown in a Cystogram. 9. Cystogram of Multiple Calculi in a Vesical Diverticulum. Mr. H. P. Winsbury-White: 10 and 11. Dilatation in the Urinary Tract in Children. 12. New Growth of Kidney. Other cases and specimens will be shown.

Friday.—5 P.M., Disease in Children. (Cases at 4.30 P.M.) 8 P.M., Epidemiology and State Medicine. Paper: Dr. E. W. Caryl Thomas (M.O.H., Dagenham, Essex): Problems in Public Health Encountered in a New Area.

MEDICO-LEGAL SOCIETY.

Thursday, Nov. 24th.—8.30 P.M. (at 11, Chandos-street, W.), Dr. F. J. McCann: The Medico-legal Significance of Impotence in the Male and in the Female. (Discussion will follow.)

HUNTERIAN SOCIETY.

Monday, Nov. 21st.—9 P.M. (at the Apothecaries Hall, Water-lane, E.C.), *Discussion on the Influence of Faith on Disease*, to be opened by the Rev. Father Woodlock, Dr. Robert Hutchison, and Dr. William Brown.

NORTH-WEST LONDON MEDICAL SOCIETY.

Tuesday, Nov. 22nd.—9 P.M. (at Willesden Constitutional Club House), Dr. James Mennell: Joint Manipulations in General Practice.

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES, 11, Chandos-street, W.

Friday, Nov. 25th.—8.30 P.M. Papers by Major F. C. Doble, Mr. T. J. Wright, and Mrs. Lynette Hemmant on *Difficult Cases—What Should A. Do?* (Discussion will follow.)

MEDICAL OFFICERS OF SCHOOLS ASSOCIATION.

Friday, Nov. 25th.—5 P.M. (at 11, Chandos-street, Cavendish-square, W.), Discussion on Mouth-breathing and Nasal Obstruction to be opened by Mr. Warwick James and Mr. Somerville Hastings.

ROYAL MEDICO-PSYCHOLOGICAL ASSOCIATION.

Tuesday, Nov. 22nd.—3 P.M. (in the Barnes Hall of the Royal Society of Medicine), Sir Farquhar Buzzard: Education in Medicine. (Maudsley lecture.)

ST. JOHN'S HOSPITAL DERMATOLOGICAL SOCIETY.

Wednesday, Nov. 23rd.—5 P.M. (at St. John's Hospital, 49, Leicester-square, W.C.), Dr. J. M. H. MacLeod: Observations on Leprosy in Great Britain at the Present Time.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS, Pall Mall East, S.W.

Tuesday, Nov. 22nd.—5 P.M., Prof. L. P. Jacks: *The Liberal Education of the Body. (Lloyd Roberts lecture.)*

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

Monday, Nov. 21st, to Saturday, Nov. 26th.—West End Hospital for Nervous Diseases, 73, Welbeck-street, W. A Course in Neurology daily at 5 P.M.—Royal Waterloo Hospital, Waterloo-road, S.E. A Course in Medicine, Surgery, and Gynæcology. Afternoons and some mornings.—Hospital for Consumption, Brompton, S.W. A Course in Practical Pathology dealing with Laboratory Methods and the Interpretation of Results. Thurs., at 11.45 A.M.—London Lock Hospital, 91, Dean-street, W. Course in Venereal Diseases, afternoons and evenings.—St. Mark's Hospital, City-road E.C. Course in [illegible] All day.—British Red Cross Clinic for [illegible] c, Marylebone-road, N.W. Six [illegible] on Diagnosis and Treatment of [illegible] Tues. and Thurs., at 8.30 P.M.—[illegible] for Nervous Diseases. In-patient Department, Gloucester-gate, N.W. Demonstration on the Fundus Oculi by Mr. R. Lindsay Rea, on Tues., 8.30 P.M. (Specially suitable for M.R.C.P. candidates.)—These courses and demonstrations are open only to Members of the Fellowship of Medicine.

HAMPSTEAD GENERAL AND NORTH-WEST LONDON HOSPITAL POST-GRADUATE SCHOOL.

Wednesday, Nov. 23rd.—4 P.M., Mr. D. H. Patey: Modern Views on the Formation of Gall-stones.

WEST LONDON HOSPITAL POST-GRADUATE CO Hammersmith, W.

Monday, Nov. 21st.—10 A.M., Genito-urinary O Skin Department. 11 A.M., Surgical Wards Eye and Gynæcological Out-patients.

GLASGOW POST-GRADUATE MEDICAL ASSOCIAT

Tuesday, Nov. 22nd.—3.30 P.M. (in the Facult Vincent-street), Dr. R. R. Morrison: Radium.

Wednesday.—4.15 P.M. (in the Royal Maternity H Prof. J. Munro Kerr: Obstetrical Cases.

Appointments

Tippett, G., M.B., M.S. Lond., has been appointed Assistant and Registrar to the Harlow Wood H Nottingham.

Certifying Surgeons under the Factory and Worksh Ashton, J. C. (Machynlleth, Montgomery); Joir (Guiseley, York).

room windows are ingeniously designed to give the maximum light and the minimum degree of shadow. One model shows a long sheet of glass, 12 feet in height, with a further domed section springing 7 feet to the roof. All the frames are of steel, and the joints are welded solid. The opening casements are airtight when closed; they are easily opened and allow a large volume of air to enter when required. Of other exhibits one of the most interesting illustrated the value of occupational therapy in the care of mental defectives.

ANOTHER GRENFELL CALENDAR

An attractive calendar for 1933 will be sold for the benefit of Sir Wilfred Grenfell's work in Labrador and Northern Newfoundland. The calendar consists of a frontispiece in colours entitled "Down North on the Labrador," and each of the twelve pages contains new photographs of the Labrador, a calendar for the month, and quotations from Grenfell's writings. The calendar is produced for the Grenfell Association by Raphael Tuck and Sons, Ltd., and the price is 3*s.* 6*d.*

"Special Reserve" Cyder.—We have received from Messrs. Wm. Gaymer and Son, Ltd. (Attleborough, Norfolk). samples of "Special Reserve" Cyder, the medical importance of which is that it contains only the barest trace of sugar, and it is therefore a suitable beverage for a diabetic patient. The dryness, however, for those whose consumption is not limited by health needs, can be modified to taste, the suggestion of the manufacturers being that it will be found a very satisfactory drink if a quarter of a grain of saccharin is added to a half-bottle of the cyder. The alcoholic content is not heavy, approximately 7·0 per cent.

A Dental Diary of Appointments.—The Dental Manufacturing Co., Ltd. (Brock House, Great Portland-street, London, W.1), has sent us a copy of an Appointment Book for 1933, which is excellently suited for its purpose. We are noticing it now because it must be a convenience to every methodical dental practitioner to be able to enter his New Year appointments from the early autumn onwards. The diary contains three columns to a page and a week in an opening, with space for half-hourly appointments from 9 A.M. to 8 P.M. At the beginning are useful notes on fees and regulations for dental benefit, and at the end is an address-book. The price is 6*s.* 6*d.* plain, 7*s.* 6*d.* interleaved with blotting-paper, 8*s.* interleaved with ruled paper (as in the copy we have received); postage 6*d.* extra.

Vacancies

For further information refer to the advertisement columns

Altrincham General Hospital.—Sen. and Jun. H.S.'s. At rate of £150 and £120 respectively.

Birmingham and Midland Eye Hospital.—Res. Surg. O. £150.
